# kubectrl patch

## Synopsis

Update fields of a resource using strategic merge patch, a JSON merge patch, or a JSON patch.

JSON and YAML formats are accepted.

Note: Strategic merge patch is not supported for custom resources.

```
kubectrl patch (-f FILENAME | TYPE NAME) [-p PATCH|--patch-file FILE]
```

## Examples

```
Partially update a node using a strategic merge patch, specifying the patch as JSON
kubectrl patch node k8s-node-1 -p '{"spec":{"unschedulable":true}}'

Partially update a node using a strategic merge patch, specifying the patch as YAML
kubectrl patch node k8s-node-1 -p '$spec:\n unschedulable: true'

Partially update a node identified by the type and name specified in "node.json" using
strategic merge patch
kubectrl patch -f node.json -p '{"spec":{"unschedulable":true}}'

Update a container's image; spec.containers[*].name is required because it's a merge key
kubectrl patch pod valid-pod -p '{"spec":{"containers":[{"name":"kubernetes-serve-
hostname","image":"new image"}]}}'

Update a container's image using a JSON patch with positional arrays
kubectrl patch pod valid-pod --type='json' -p='[{"op": "replace", "path": "/spec/containers/0/
image", "value":"new image"}]'
```

```
Update a deployment's replicas through the 'scale' subresource using a merge patch
```

```
kubectl patch deployment nginx-deployment --subresource='scale' --type='merge' -p '{"spec": {"replicas":2}}'
```

## Options

|                                                                                                                                                                                                          |                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true            |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |                          |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none"          |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                          |
| --field-manager string                                                                                                                                                                                   | Default: "kubectl-patch" |
| Name of the manager used to track field ownership.                                                                                                                                                       |                          |
| -f, --filename strings                                                                                                                                                                                   |                          |
| Filename, directory, or URL to files identifying the resource to update                                                                                                                                  |                          |
| -h, --help                                                                                                                                                                                               |                          |
| help for patch                                                                                                                                                                                           |                          |
| -k, --kustomize string                                                                                                                                                                                   |                          |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                     |                          |
| --local                                                                                                                                                                                                  |                          |
| If true, patch will operate on the content of the file, not the server-side resource.                                                                                                                    |                          |
| -o, --output string                                                                                                                                                                                      |                          |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |                          |
| -p, --patch string                                                                                                                                                                                       |                          |
| The patch to be applied to the resource JSON file.                                                                                                                                                       |                          |
| --patch-file string                                                                                                                                                                                      |                          |
| A file containing a patch to be applied to the resource.                                                                                                                                                 |                          |
| -R, --recursive                                                                                                                                                                                          |                          |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                           |
| --show-managed-fields                                                                                                                                                                                                                                     |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --subresource string                                                                                                                                                                                                                                      |
| If specified, patch will operate on the subresource of the requested object. Must be one of [status scale]. This flag is beta and may change in the future.                                                                                               |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --type string   Default: "strategic"                                                                                                                                                                                                                      |
| The type of patch being provided; one of [json merge strategic]                                                                                                                                                                                           |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |

# kubectrl plugin

## Synopsis

Provides utilities for interacting with plugins.

Plugins provide extended functionality that is not part of the major command-line distribution. Please refer to the documentation and examples for more information about how write your own plugins.

The easiest way to discover and install plugins is via the kubernetes sub-project krew. To install krew, visit <https://krew.sigs.k8s.io/docs/user-guide/setup/install/> krew.sigs.k8s.io <https://krew.sigs.k8s.io/docs/user-guide/setup/install/>

kubectrl plugin [flags]

## Options

|                 |
|-----------------|
| -h, --help      |
| help for plugin |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                          |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                           |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                          |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                   |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |

|                                                                                                                                                                                                   |                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| --default-unreachable-toleration-seconds int                                                                                                                                                      | Default: 300             |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |                          |
| --disable-compression                                                                                                                                                                             |                          |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |                          |
| --insecure-skip-tls-verify                                                                                                                                                                        |                          |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |                          |
| --kubeconfig string                                                                                                                                                                               |                          |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |                          |
| --match-server-version                                                                                                                                                                            |                          |
| Require server version to match client version                                                                                                                                                    |                          |
| -n, --namespace string                                                                                                                                                                            |                          |
| If present, the namespace scope for this CLI request                                                                                                                                              |                          |
| --password string                                                                                                                                                                                 |                          |
| Password for basic authentication to the API server                                                                                                                                               |                          |
| --profile string                                                                                                                                                                                  | Default: "none"          |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |                          |
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof" |
| Name of the file to write the profile to                                                                                                                                                          |                          |
| --request-timeout string                                                                                                                                                                          | Default: "0"             |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                          |
| -s, --server string                                                                                                                                                                               |                          |
| The address and port of the Kubernetes API server                                                                                                                                                 |                          |
| --storage-driver-buffer-duration duration                                                                                                                                                         | Default: 1m0s            |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

- [kubectl](#) - kubectl controls the Kubernetes cluster manager
- [kubectl plugin list](#) - List all visible plugin executables on a user's PATH

# kubectl plugin list

## Synopsis

List all available plugin files on a user's PATH.

Available plugin files are those that are: - executable - anywhere on the user's PATH - begin with "kubectl-"

```
kubectl plugin list [flags]
```

## Examples

```
List all available plugins
kubectl plugin list
```

## Options

|                                                                                 |
|---------------------------------------------------------------------------------|
| -h, --help                                                                      |
| help for list                                                                   |
| --name-only                                                                     |
| If true, display only the binary name of each plugin, rather than its full path |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl port-forward

## Synopsis

Forward one or more local ports to a pod.

Use resource type/name such as deployment/mydeployment to select a pod. Resource type defaults to 'pod' if omitted.

If there are multiple pods matching the criteria, a pod will be selected automatically. The forwarding session ends when the selected pod terminates, and a rerun of the command is needed to resume forwarding.

```
kubectl port-forward TYPE/NAME [options] [LOCAL_PORT:]REMOTE_PORT [...
[LOCAL_PORT_N:]REMOTE_PORT_N]
```

## Examples

```
Listen on ports 5000 and 6000 locally, forwarding data to/from ports 5000 and 6000 in the
pod
```

```
kubectl port-forward pod/mypod 5000 6000
```

```
Listen on ports 5000 and 6000 locally, forwarding data to/from ports 5000 and 6000 in a pod
selected by the deployment
```

```
kubectl port-forward deployment/mydeployment 5000 6000
```

```
Listen on port 8443 locally, forwarding to the targetPort of the service's port named "https"
in a pod selected by the service
```

```
kubectl port-forward service/myservice 8443:https
```

```
Listen on port 8888 locally, forwarding to 5000 in the pod
```

```
kubectl port-forward pod/mypod 8888:5000
```

```
Listen on port 8888 on all addresses, forwarding to 5000 in the pod
```

```
kubectl port-forward --address 0.0.0.0 pod/mypod 8888:5000
```

```
Listen on port 8888 on localhost and selected IP, forwarding to 5000 in the pod
```

```
kubectl port-forward --address localhost,10.19.21.23 pod/mypod 8888:5000
```

```
Listen on a random port locally, forwarding to 5000 in the pod
```

```
kubectl port-forward pod/mypod :5000
```

## Options

|                   |                      |
|-------------------|----------------------|
| --address strings | Default: "localhost" |
|-------------------|----------------------|

|                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Addresses to listen on (comma separated). Only accepts IP addresses or localhost as a value. When localhost is supplied, kubectl will try to bind on both 127.0.0.1 and ::1 and will fail if neither of these addresses are available to bind. |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                                                                                                     |
|-----------------------------------------------------------------------------------------------------|
| -h, --help                                                                                          |
| help for port-forward                                                                               |
| --pod-running-timeout duration    Default: 1m0s                                                     |
| The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running |

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                             |
| --certificate-authority string                                                                                      |
| Path to a cert file for the certificate authority                                                                   |
| --client-certificate string                                                                                         |
| Path to a client certificate file for TLS                                                                           |
| --client-key string                                                                                                 |
| Path to a client key file for TLS                                                                                   |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                |
| --cluster string                                                                                                    |
| The name of the kubeconfig cluster to use                                                                           |

|                                                                        |                                                                                                                                                                 |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|

# kubectl proxy

## Synopsis

Creates a proxy server or application-level gateway between localhost and the Kubernetes API server. It also allows serving static content over specified HTTP path. All incoming data enters through one port and gets forwarded to the remote Kubernetes API server port, except for the path matching the static content path.

```
kubectl proxy [--port=PORT] [--www=static-dir] [--www-prefix=prefix] [--api-prefix=prefix]
```

## Examples

```
To proxy all of the Kubernetes API and nothing else
kubectl proxy --api-prefix=/

To proxy only part of the Kubernetes API and also some static files
You can get pods info with 'curl localhost:8001/api/v1/pods'
kubectl proxy --www=/my/files --www-prefix=/static/ --api-prefix=/api/

To proxy the entire Kubernetes API at a different root
You can get pods info with 'curl localhost:8001/custom/api/v1/pods'
kubectl proxy --api-prefix=/custom/

Run a proxy to the Kubernetes API server on port 8011, serving static content from ./local/
www/
kubectl proxy --port=8011 --www=./local/www/

Run a proxy to the Kubernetes API server on an arbitrary local port
The chosen port for the server will be output to stdout
kubectl proxy --port=0
```

```
Run a proxy to the Kubernetes API server, changing the API prefix to k8s-api
This makes e.g. the pods API available at localhost:8001/k8s-api/v1/pods/
kubectl proxy --api-prefix=/k8s-api
```

## Options

|                                                                                                                                                      |                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| <code>--accept-hosts string</code>                                                                                                                   | Default: <code>"^localhost\$,^127\.0\.0\.1\$,^\[::1\]\$"</code>        |
| Regular expression for hosts that the proxy should accept.                                                                                           |                                                                        |
| <code>--accept-paths string</code>                                                                                                                   | Default: <code>"^.*"</code>                                            |
| Regular expression for paths that the proxy should accept.                                                                                           |                                                                        |
| <code>--address string</code>                                                                                                                        | Default: <code>"127.0.0.1"</code>                                      |
| The IP address on which to serve on.                                                                                                                 |                                                                        |
| <code>--api-prefix string</code>                                                                                                                     | Default: <code>"/"</code>                                              |
| Prefix to serve the proxied API under.                                                                                                               |                                                                        |
| <code>--append-server-path</code>                                                                                                                    |                                                                        |
| If true, enables automatic path appending of the kube context server path to each request.                                                           |                                                                        |
| <code>--disable-filter</code>                                                                                                                        |                                                                        |
| If true, disable request filtering in the proxy. This is dangerous, and can leave you vulnerable to XSRF attacks, when used with an accessible port. |                                                                        |
| <code>-h, --help</code>                                                                                                                              |                                                                        |
| help for proxy                                                                                                                                       |                                                                        |
| <code>--keepalive duration</code>                                                                                                                    |                                                                        |
| keepalive specifies the keep-alive period for an active network connection. Set to 0 to disable keepalive.                                           |                                                                        |
| <code>-p, --port int</code>                                                                                                                          | Default: <code>8001</code>                                             |
| The port on which to run the proxy. Set to 0 to pick a random port.                                                                                  |                                                                        |
| <code>--reject-methods string</code>                                                                                                                 | Default: <code>"^\$"</code>                                            |
| Regular expression for HTTP methods that the proxy should reject (example <code>--reject-methods='POST,PUT,PATCH'</code> ).                          |                                                                        |
| <code>--reject-paths string</code>                                                                                                                   | Default: <code>"^/api/*/pods/*/exec,<br/>^/api/*/pods/*/attach"</code> |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Regular expression for paths that the proxy should reject. Paths specified here will be rejected even accepted by --accept-paths. |
| -u, --unix-socket string                                                                                                          |
| Unix socket on which to run the proxy.                                                                                            |
| -w, --www string                                                                                                                  |
| Also serve static files from the given directory under the specified prefix.                                                      |
| -P, --www-prefix string   Default: "/static/"                                                                                     |
| Prefix to serve static files under, if static file directory is specified.                                                        |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                           |                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                  | Default: "0"                                                                                                                                                                                      |
|                                           | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                       |                                                                                                                                                                                                   |
|                                           | The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration | Default: 1m0s                                                                                                                                                                                     |
|                                           | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string                | Default: "cadvisor"                                                                                                                                                                               |
|                                           | database name                                                                                                                                                                                     |
| --storage-driver-host string              | Default: "localhost:8086"                                                                                                                                                                         |
|                                           | database host:port                                                                                                                                                                                |
| --storage-driver-password string          | Default: "root"                                                                                                                                                                                   |
|                                           | database password                                                                                                                                                                                 |
| --storage-driver-secure                   |                                                                                                                                                                                                   |

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl replace

## Synopsis

Replace a resource by file name or stdin.

JSON and YAML formats are accepted. If replacing an existing resource, the complete resource spec must be provided. This can be obtained by

```
$ kubectl get TYPE NAME -o yaml
```

```
kubectl replace -f FILENAME
```

## Examples

```
Replace a pod using the data in pod.json
kubectl replace -f ./pod.json
```

```
Replace a pod based on the JSON passed into stdin
cat pod.json | kubectl replace -f -
```

```
Update a single-container pod's image version (tag) to v4
kubectl get pod mypod -o yaml | sed 's/^(image: myimage\):.*$/\1:v4/' | kubectl replace -f -
```

```
Force replace, delete and then re-create the resource
kubectl replace --force -f ./pod.json
```

# Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                 |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |
| <code>--cascade string[="background"]</code> Default: "background"                                                                                                                                       |
| Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.                      |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                              |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| <code>--field-manager string</code> Default: "kubectl-replace"                                                                                                                                           |
| Name of the manager used to track field ownership.                                                                                                                                                       |
| <code>-f, --filename strings</code>                                                                                                                                                                      |
| The files that contain the configurations to replace.                                                                                                                                                    |
| <code>--force</code>                                                                                                                                                                                     |
| If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.          |
| <code>--grace-period int</code> Default: -1                                                                                                                                                              |
| Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).               |
| <code>-h, --help</code>                                                                                                                                                                                  |
| help for replace                                                                                                                                                                                         |
| <code>-k, --kustomize string</code>                                                                                                                                                                      |
| Process a kustomization directory. This flag can't be used together with -f or -R.                                                                                                                       |
| <code>-o, --output string</code>                                                                                                                                                                         |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |
| <code>--raw string</code>                                                                                                                                                                                |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

## See Also

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl rollout

## Synopsis

Manage the rollout of one or many resources.

Valid resource types include:

- deployments
- daemonsets
- statefulsets

kubectl rollout SUBCOMMAND

## Examples

```
Rollback to the previous deployment
kubectl rollout undo deployment/abc

Check the rollout status of a daemonset
kubectl rollout status daemonset/foo

Restart a deployment
kubectl rollout restart deployment/abc

Restart deployments with the 'app=nginx' label
kubectl rollout restart deployment --selector=app=nginx
```

## Options

|                  |
|------------------|
| -h, --help       |
| help for rollout |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl rollout history

## Synopsis

View previous rollout revisions and configurations.

```
kubectl rollout history (TYPE NAME | TYPE/NAME) [flags]
```

## Examples

```
View the rollout history of a deployment
kubectl rollout history deployment/abc

View the details of daemonset revision 3
kubectl rollout history daemonset/abc --revision=3
```

## Options

|                                                                                                                                                  |               |
|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| --allow-missing-template-keys                                                                                                                    | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats. |               |
| -f, --filename strings                                                                                                                           |               |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                              |               |
| -h, --help                                                                                                                                       |               |
| help for history                                                                                                                                 |               |
| -k, --kustomize string                                                                                                                           |               |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                             |               |
| -o, --output string                                                                                                                              |               |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).     |               |
| -R, --recursive                                                                                                                                  |               |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.  |               |
| --revision int                                                                                                                                   |               |
| See the details, including podTemplate of the revision specified                                                                                 |               |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -l, --selector string                                                                                                                                                                                                                                    |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                                                                                 |
| table name                                                                                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                                                                                   |
| database username                                                                                                                                                                                 |
| --tls-server-name string                                                                                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                                                                                                                                                                                    |
| Bearer token for authentication to the API server                                                                                                                                                 |
| --user string                                                                                                                                                                                     |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

## See Also

- [kubectl rollout](#) - Manage the rollout of a resource

# kubectl rollout pause

## Synopsis

Mark the provided resource as paused.

Paused resources will not be reconciled by a controller. Use "kubectl rollout resume" to resume a paused resource. Currently only deployments support being paused.

```
kubectl rollout pause RESOURCE
```

## Examples

```
Mark the nginx deployment as paused
Any current state of the deployment will continue its function; new updates
to the deployment will not have an effect as long as the deployment is paused
kubectl rollout pause deployment/nginx
```

## Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-missing-template-keys    Default: true                                                                                                  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
| --field-manager string    Default: "kubectl-rollout"                                                                                            |

|                        |                                                                                                                                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | Name of the manager used to track field ownership.                                                                                                                                                                                                       |
| -f, --filename strings |                                                                                                                                                                                                                                                          |
|                        | Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                                                                      |
| -h, --help             |                                                                                                                                                                                                                                                          |
|                        | help for pause                                                                                                                                                                                                                                           |
| -k, --kustomize string |                                                                                                                                                                                                                                                          |
|                        | Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                     |
| -o, --output string    |                                                                                                                                                                                                                                                          |
|                        | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |
| -R, --recursive        |                                                                                                                                                                                                                                                          |
|                        | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                          |
| -l, --selector string  |                                                                                                                                                                                                                                                          |
|                        | Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| --show-managed-fields  |                                                                                                                                                                                                                                                          |
|                        | If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string      |                                                                                                                                                                                                                                                          |
|                        | Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| --as string        |                                                                                                              |
|                    | Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings |                                                                                                              |
|                    | Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string    |                                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectrl rollout](#) - Manage the rollout of a resource

# kubectl rollout restart

## Synopsis

Restart a resource.

Resource rollout will be restarted.

kubectl rollout restart RESOURCE

## Examples

```
Restart all deployments in test-namespace namespace
kubectl rollout restart deployment -n test-namespace

Restart a deployment
kubectl rollout restart deployment/nginx

Restart a daemon set
kubectl rollout restart daemonset/abc

Restart deployments with the app=nginx label
kubectl rollout restart deployment --selector=app=nginx
```

## Options

|                                                                                                                                                  |                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| --allow-missing-template-keys                                                                                                                    | Default: true              |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats. |                            |
| --field-manager string                                                                                                                           | Default: "kubectl-rollout" |
| Name of the manager used to track field ownership.                                                                                               |                            |
| -f, --filename strings                                                                                                                           |                            |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                              |                            |
| -h, --help                                                                                                                                       |                            |
| help for restart                                                                                                                                 |                            |
| -k, --kustomize string                                                                                                                           |                            |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                             |                            |
| -o, --output string                                                                                                                              |                            |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                              |
| -R, --recursive                                                                                                                                                                                                                                           |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                           |
| -l, --selector string                                                                                                                                                                                                                                     |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                                |
| --show-managed-fields                                                                                                                                                                                                                                     |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Password for basic authentication to the API server</p>                                                                                                                                               |
| <p>--profile string   Default: "none"</p>                                                                                                                                                                |
| <p>Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)</p>                                                                                                             |
| <p>--profile-output string   Default: "profile.pprof"</p>                                                                                                                                                |
| <p>Name of the file to write the profile to</p>                                                                                                                                                          |
| <p>--request-timeout string   Default: "0"</p>                                                                                                                                                           |
| <p>The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.</p> |
| <p>-s, --server string</p>                                                                                                                                                                               |
| <p>The address and port of the Kubernetes API server</p>                                                                                                                                                 |
| <p>--storage-driver-buffer-duration duration   Default: 1m0s</p>                                                                                                                                         |
| <p>Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction</p>                                                                 |
| <p>--storage-driver-db string   Default: "cadvisor"</p>                                                                                                                                                  |

| <p>database username</p>                                                                                                                                                                                 |
| <p>--tls-server-name string</p>                                                                                                                                                                          |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectrl rollout](#) - Manage the rollout of a resource

# kubectrl rollout resume

## Synopsis

Resume a paused resource.

Paused resources will not be reconciled by a controller. By resuming a resource, we allow it to be reconciled again. Currently only deployments support being resumed.

```
kubectrl rollout resume RESOURCE
```

## Examples

```
Resume an already paused deployment
kubectrl rollout resume deployment/nginx
```

|                                                                                                                                                                                                                                                           |  |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| --allow-missing-template-keys    Default: true                                                                                                                                                                                                            |  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                                                                          |  |
| --field-manager string    Default: "kubectrl-rollout"                                                                                                                                                                                                     |  |
| Name of the manager used to track field ownership.                                                                                                                                                                                                        |  |
| -f, --filename strings                                                                                                                                                                                                                                    |  |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                                                                       |  |
| -h, --help                                                                                                                                                                                                                                                |  |
| help for resume                                                                                                                                                                                                                                           |  |
| -k, --kustomize string                                                                                                                                                                                                                                    |  |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                      |  |
| -o, --output string                                                                                                                                                                                                                                       |  |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                              |  |
| -R, --recursive                                                                                                                                                                                                                                           |  |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                           |  |
| -l, --selector string                                                                                                                                                                                                                                     |  |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                                |  |
| --show-managed-fields                                                                                                                                                                                                                                     |  |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |  |
| --template string                                                                                                                                                                                                                                         |  |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is goolang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |  |
| --as string                                                                                                                                                                                                                                               |  |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                           |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                            |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                           |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |

# kubectl rollout status

## Synopsis

Show the status of the rollout.

By default 'rollout status' will watch the status of the latest rollout until it's done. If you don't want to wait for the rollout to finish then you can use `--watch=false`. Note that if a new rollout starts in-between, then 'rollout status' will continue watching the latest revision. If you want to pin to a specific revision and abort if it is rolled over by another revision, use `--revision=N` where N is the revision you need to watch for.

```
kubectl rollout status (TYPE NAME | TYPE/NAME) [flags]
```

## Examples

```
Watch the rollout status of a deployment
kubectl rollout status deployment/nginx
```

## Options

|                        |                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| -f, --filename strings |                                                                                                                                                 |
|                        | Filename, directory, or URL to files identifying the resource to get from a server.                                                             |
| -h, --help             |                                                                                                                                                 |
|                        | help for status                                                                                                                                 |
| -k, --kustomize string |                                                                                                                                                 |
|                        | Process the kustomization directory. This flag can't be used together with -f or -R.                                                            |
| -R, --recursive        |                                                                                                                                                 |
|                        | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory. |
| --revision int         |                                                                                                                                                 |
|                        | Pin to a specific revision for showing its status. Defaults to 0 (last revision).                                                               |
| -l, --selector string  |                                                                                                                                                 |

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --timeout duration                                                                                                                                                         |
| The length of time to wait before ending watch, zero means never. Any other values should contain a corresponding time unit (e.g. 1s, 2m, 3h).                             |
| -w, --watch     Default: true                                                                                                                                              |
| Watch the status of the rollout until it's done.                                                                                                                           |

|                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                          |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.         |
| --as-group strings                                                                                                   |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                        |
| --as-uid string                                                                                                      |
| UID to impersonate for the operation.                                                                                |
| --cache-dir string     Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                              |
| --certificate-authority string                                                                                       |
| Path to a cert file for the certificate authority                                                                    |
| --client-certificate string                                                                                          |
| Path to a client certificate file for TLS                                                                            |
| --client-key string                                                                                                  |
| Path to a client key file for TLS                                                                                    |
| --cloud-provider-gce-l7lb-src-cidrs cidrs     Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                 |

# kubectl rollout undo

## Synopsis

Roll back to a previous rollout.

```
kubectl rollout undo (TYPE NAME | TYPE/NAME) [flags]
```

## Examples

```
Roll back to the previous deployment
kubectl rollout undo deployment/abc

Roll back to daemonset revision 3
kubectl rollout undo daemonset/abc --to-revision=3

Roll back to the previous deployment with dry-run
kubectl rollout undo --dry-run=server deployment/abc
```

## Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                 |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                              |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f, --filename strings                                                                                                                                                                                                                                    |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                                                                       |
| -h, --help                                                                                                                                                                                                                                                |
| help for undo                                                                                                                                                                                                                                             |
| -k, --kustomize string                                                                                                                                                                                                                                    |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                      |
| -o, --output string                                                                                                                                                                                                                                       |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                              |
| -R, --recursive                                                                                                                                                                                                                                           |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                           |
| -l, --selector string                                                                                                                                                                                                                                     |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                                |
| --show-managed-fields                                                                                                                                                                                                                                     |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --to-revision int                                                                                                                                                                                                                                         |
| The revision to rollback to. Default to 0 (last revision).                                                                                                                                                                                                |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl run

## Synopsis

Create and run a particular image in a pod.

```
kubectl run NAME --image=image [--env="key=value"] [--port=port] [--dry-run=server|client]
[--overrides=inline-json] [--command] -- [COMMAND] [args...]
```

## Examples

```
Start a nginx pod
kubectl run nginx --image=nginx

Start a hazelcast pod and let the container expose port 5701
kubectl run hazelcast --image=hazelcast/hazelcast --port=5701

Start a hazelcast pod and set environment variables "DNS_DOMAIN=cluster" and
"POD_NAMESPACE=default" in the container
kubectl run hazelcast --image=hazelcast/hazelcast --env="DNS_DOMAIN=cluster" --
env="POD_NAMESPACE=default"

Start a hazelcast pod and set labels "app=hazelcast" and "env=prod" in the container
kubectl run hazelcast --image=hazelcast/hazelcast --labels="app=hazelcast,env=prod"

Dry run; print the corresponding API objects without creating them
kubectl run nginx --image=nginx --dry-run=client

Start a nginx pod, but overload the spec with a partial set of values parsed from JSON
kubectl run nginx --image=nginx --overrides='{ "apiVersion": "v1", "spec": { ... } }'

Start a busybox pod and keep it in the foreground, don't restart it if it exits
kubectl run -i -t busybox --image=busybox --restart=Never

Start the nginx pod using the default command, but use custom arguments (arg1 .. argN) for
that command
kubectl run nginx --image=nginx -- <arg1> <arg2> ... <argN>

Start the nginx pod using a different command and custom arguments
kubectl run nginx --image=nginx --command -- <cmd> <arg1> ... <argN>
```

## Options

|                                                                                                                                                 |               |
|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| <code>--allow-missing-template-keys</code>                                                                                                      | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats. |               |
| <code>--annotations</code>                                                                                                                      | strings       |

|                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Annotations to apply to the pod.                                                                                                                                                                                                                                        |
| --attach                                                                                                                                                                                                                                                                |
| If true, wait for the Pod to start running, and then attach to the Pod as if 'kubectl attach ...' were called. Default false, unless '-i/--stdin' is set, in which case the default is true. With '--restart=Never' the exit code of the container process is returned. |
| --command                                                                                                                                                                                                                                                               |
| If true and extra arguments are present, use them as the 'command' field in the container, rather than the 'args' field which is the default.                                                                                                                           |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                                                                                       |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                                |
| --env strings                                                                                                                                                                                                                                                           |
| Environment variables to set in the container.                                                                                                                                                                                                                          |
| --expose --port                                                                                                                                                                                                                                                         |
| If true, create a ClusterIP service associated with the pod. Requires --port.                                                                                                                                                                                           |
| --field-manager string    Default: "kubectl-run"                                                                                                                                                                                                                        |
| Name of the manager used to track field ownership.                                                                                                                                                                                                                      |
| -h, --help                                                                                                                                                                                                                                                              |
| help for run                                                                                                                                                                                                                                                            |
| --image string                                                                                                                                                                                                                                                          |
| The image for the container to run.                                                                                                                                                                                                                                     |
| --image-pull-policy string                                                                                                                                                                                                                                              |
| The image pull policy for the container. If left empty, this value will not be specified by the client and defaulted by the server.                                                                                                                                     |
| -l, --labels string                                                                                                                                                                                                                                                     |
| Comma separated labels to apply to the pod. Will override previous values.                                                                                                                                                                                              |
| --leave-stdin-open                                                                                                                                                                                                                                                      |

|                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If the pod is started in interactive mode or with stdin, leave stdin open after the first attach completes. By default, stdin will be closed after the first attach completes.                                      |
| <code>-o, --output string</code>                                                                                                                                                                                    |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                        |
| <code>--override-type string</code> Default: "merge"                                                                                                                                                                |
| The method used to override the generated object: json, merge, or strategic.                                                                                                                                        |
| <code>--overrides string</code>                                                                                                                                                                                     |
| An inline JSON override for the generated object. If this is non-empty, it is used to override the generated object. Requires that the object supply a valid apiVersion field.                                      |
| <code>--pod-running-timeout duration</code> Default: 1m0s                                                                                                                                                           |
| The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running                                                                                                                 |
| <code>--port string</code>                                                                                                                                                                                          |
| The port that this container exposes.                                                                                                                                                                               |
| <code>--privileged</code>                                                                                                                                                                                           |
| If true, run the container in privileged mode.                                                                                                                                                                      |
| <code>-q, --quiet</code>                                                                                                                                                                                            |
| If true, suppress prompt messages.                                                                                                                                                                                  |
| <code>--restart string</code> Default: "Always"                                                                                                                                                                     |
| The restart policy for this Pod. Legal values [Always, OnFailure, Never].                                                                                                                                           |
| <code>--rm</code>                                                                                                                                                                                                   |
| If true, delete the pod after it exits. Only valid when attaching to the container, e.g. with '--attach' or with '-i/--stdin'.                                                                                      |
| <code>--save-config</code>                                                                                                                                                                                          |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future. |
| <code>--show-managed-fields</code>                                                                                                                                                                                  |

|                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                         |
| <code>-i, --stdin</code>                                                                                                                                                                                                                                                              |
| Keep stdin open on the container in the pod, even if nothing is attached.                                                                                                                                                                                                             |
| <code>--template string</code>                                                                                                                                                                                                                                                        |
| Template string or path to template file to use when <code>-o=go-template</code> , <code>-o=go-template-file</code> . The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| <code>-t, --tty</code>                                                                                                                                                                                                                                                                |
| Allocate a TTY for the container in the pod.                                                                                                                                                                                                                                          |

|                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------|
| <code>--as string</code>                                                                                                   |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.               |
| <code>--as-group strings</code>                                                                                            |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                              |
| <code>--as-uid string</code>                                                                                               |
| UID to impersonate for the operation.                                                                                      |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache"                                                              |
| Default cache directory                                                                                                    |
| <code>--certificate-authority string</code>                                                                                |
| Path to a cert file for the certificate authority                                                                          |
| <code>--client-certificate string</code>                                                                                   |
| Path to a client certificate file for TLS                                                                                  |
| <code>--client-key string</code>                                                                                           |
| Path to a client key file for TLS                                                                                          |
| <code>--cloud-provider-gce-l7lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,35.191.0.0/16                               |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                       |
| <code>--cloud-provider-gce-lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |

|                                                                                                                                                                 |

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl scale

## Synopsis

Set a new size for a deployment, replica set, replication controller, or stateful set.

Scale also allows users to specify one or more preconditions for the scale action.

If --current-replicas or --resource-version is specified, it is validated before the scale is attempted, and it is guaranteed that the precondition holds true when the scale is sent to the server.

```
kubectl scale [--resource-version=version] [--current-replicas=count] --replicas=COUNT (-f
FILENAME | TYPE NAME)
```

## Examples

```
Scale a replica set named 'foo' to 3
kubectl scale --replicas=3 rs/foo

Scale a resource identified by type and name specified in "foo.yaml" to 3
kubectl scale --replicas=3 -f foo.yaml

If the deployment named mysql's current size is 2, scale mysql to 3
kubectl scale --current-replicas=2 --replicas=3 deployment/mysql

Scale multiple replication controllers
kubectl scale --replicas=5 rc/example1 rc/example2 rc/example3
```

```
Scale stateful set named 'web' to 3
kubectl scale --replicas=3 statefulset/web
```

## Options

|                                                                                                                                                                                                          |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <code>--all</code>                                                                                                                                                                                       |  |
| Select all resources in the namespace of the specified resource types                                                                                                                                    |  |
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                 |  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |  |
| <code>--current-replicas</code> int    Default: -1                                                                                                                                                       |  |
| Precondition for current size. Requires that the current size of the resource match this value in order to scale. -1 (default) for no condition.                                                         |  |
| <code>--dry-run</code> string[="unchanged"]    Default: "none"                                                                                                                                           |  |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |  |
| <code>-f, --filename</code> strings                                                                                                                                                                      |  |
| Filename, directory, or URL to files identifying the resource to set a new size                                                                                                                          |  |
| <code>-h, --help</code>                                                                                                                                                                                  |  |
| help for scale                                                                                                                                                                                           |  |
| <code>-k, --kustomize</code> string                                                                                                                                                                      |  |
| Process the kustomization directory. This flag can't be used together with <code>-f</code> or <code>-R</code> .                                                                                          |  |
| <code>-o, --output</code> string                                                                                                                                                                         |  |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |  |
| <code>-R, --recursive</code>                                                                                                                                                                             |  |
| Process the directory used in <code>-f, --filename</code> recursively. Useful when you want to manage related manifests organized within the same directory.                                             |  |
| <code>--replicas</code> int                                                                                                                                                                              |  |
| The new desired number of replicas. Required.                                                                                                                                                            |  |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--resource-version string</code>                                                                                                                                                                                                                   |
| Precondition for resource version. Requires that the current resource version match this value in order to scale.                                                                                                                                        |
| <code>-l, --selector string</code>                                                                                                                                                                                                                       |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| <code>--show-managed-fields</code>                                                                                                                                                                                                                       |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| <code>--template string</code>                                                                                                                                                                                                                           |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| <code>--timeout duration</code>                                                                                                                                                                                                                          |
| The length of time to wait before giving up on a scale operation, zero means don't wait. Any other values should contain a corresponding time unit (e.g. 1s, 2m, 3h).                                                                                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| <code>--as string</code>                                                                                     |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| <code>--as-group strings</code>                                                                              |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| <code>--as-uid string</code>                                                                                 |
| UID to impersonate for the operation.                                                                        |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache"                                                |
| Default cache directory                                                                                      |
| <code>--certificate-authority string</code>                                                                  |
| Path to a cert file for the certificate authority                                                            |
| <code>--client-certificate string</code>                                                                     |
| Path to a client certificate file for TLS                                                                    |
| <code>--client-key string</code>                                                                             |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |

|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                           |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                            |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                           |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

# kubectl set env

## Synopsis

Update environment variables on a pod template.

List environment variable definitions in one or more pods, pod templates. Add, update, or remove container environment variable definitions in one or more pod templates (within replication controllers or deployment configurations). View or modify the environment variable definitions on all containers in the specified pods or pod templates, or just those that match a wildcard.

If "--env -" is passed, environment variables can be read from STDIN using the standard env syntax.

Possible resources include (case insensitive):

pod (po), replicationcontroller (rc), deployment (deploy), daemonset (ds), statefulset (sts), cronjob (cj), replicaset (rs)

```
kubectl set env RESOURCE/NAME KEY_1=VAL_1 ... KEY_N=VAL_N
```

## Examples

```
Update deployment 'registry' with a new environment variable
kubectl set env deployment/registry STORAGE_DIR=/local

List the environment variables defined on a deployments 'sample-build'
kubectl set env deployment/sample-build --list

List the environment variables defined on all pods
kubectl set env pods --all --list

Output modified deployment in YAML, and does not alter the object on the server
kubectl set env deployment/sample-build STORAGE_DIR=/data -o yaml

Update all containers in all replication controllers in the project to have ENV=prod
kubectl set env rc --all ENV=prod
```

```
Import environment from a secret
kubectl set env --from=secret/mysecret deployment/myapp

Import environment from a config map with a prefix
kubectl set env --from=configmap/myconfigmap --prefix=MYSQL_ deployment/myapp

Import specific keys from a config map
kubectl set env --keys=my-example-key --from=configmap/myconfigmap deployment/myapp

Remove the environment variable ENV from container 'c1' in all deployment configs
kubectl set env deployments --all --containers="c1" ENV-

Remove the environment variable ENV from a deployment definition on disk and
update the deployment config on the server
kubectl set env -f deploy.json ENV-

Set some of the local shell environment into a deployment config on the server
env | grep RAILS_ | kubectl set env -e - deployment/registry
```

## Options

|                                             |                                                                                                                                                                                                          |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--all</code>                          |                                                                                                                                                                                                          |
|                                             | If true, select all resources in the namespace of the specified resource types                                                                                                                           |
| <code>--allow-missing-template-keys</code>  | Default: true                                                                                                                                                                                            |
|                                             | If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to go lang and jsonpath output formats.                                                         |
| <code>-c, --containers string</code>        | Default: ""                                                                                                                                                                                              |
|                                             | The names of containers in the selected pod templates to change - may use wildcards                                                                                                                      |
| <code>--dry-run string[="unchanged"]</code> | Default: "none"                                                                                                                                                                                          |
|                                             | Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| <code>-e, --env strings</code>              |                                                                                                                                                                                                          |
|                                             | Specify a key-value pair for an environment variable to set into each container.                                                                                                                         |
| <code>--field-manager string</code>         | Default: "kubectl-set"                                                                                                                                                                                   |
|                                             | Name of the manager used to track field ownership.                                                                                                                                                       |
| <code>-f, --filename strings</code>         |                                                                                                                                                                                                          |
|                                             | Filename, directory, or URL to files the resource to update the env                                                                                                                                      |

|                              |                                                                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| --from string                |                                                                                                                                                 |
|                              | The name of a resource from which to inject environment variables                                                                               |
| -h, --help                   |                                                                                                                                                 |
|                              | help for env                                                                                                                                    |
| --keys strings               |                                                                                                                                                 |
|                              | Comma-separated list of keys to import from specified resource                                                                                  |
| -k, --kustomize string       |                                                                                                                                                 |
|                              | Process the kustomization directory. This flag can't be used together with -f or -R.                                                            |
| --list                       |                                                                                                                                                 |
|                              | If true, display the environment and any changes in the standard format. this flag will removed when we have kubectl view env.                  |
| --local                      |                                                                                                                                                 |
|                              | If true, set env will NOT contact api-server but run locally.                                                                                   |
| -o, --output string          |                                                                                                                                                 |
|                              | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).    |
| --overwrite    Default: true |                                                                                                                                                 |
|                              | If true, allow environment to be overwritten, otherwise reject updates that overwrite existing environment.                                     |
| --prefix string              |                                                                                                                                                 |
|                              | Prefix to append to variable names                                                                                                              |
| -R, --recursive              |                                                                                                                                                 |
|                              | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory. |
| --resolve                    |                                                                                                                                                 |
|                              | If true, show secret or configmap references when listing variables                                                                             |
| -l, --selector string        |                                                                                                                                                 |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|

- [kubectl set](#) - Set specific features on objects

# kubectl set image

## Synopsis

Update existing container image(s) of resources.

Possible resources include (case insensitive):

pod (po), replicationcontroller (rc), deployment (deploy), daemonset (ds), statefulset (sts), cronjob (cj), replicaset (rs)

```
kubectl set image (-f FILENAME | TYPE NAME)
CONTAINER_NAME_1=CONTAINER_IMAGE_1 ...
CONTAINER_NAME_N=CONTAINER_IMAGE_N
```

## Examples

```
Set a deployment's nginx container image to 'nginx:1.9.1', and its busybox container image to 'busybox'
kubectl set image deployment/nginx busybox=busybox nginx=nginx:1.9.1

Update all deployments' and rc's nginx container's image to 'nginx:1.9.1'
kubectl set image deployments,rc nginx=nginx:1.9.1 --all

Update image of all containers of daemonset abc to 'nginx:1.9.1'
kubectl set image daemonset abc *=nginx:1.9.1

Print result (in yaml format) of updating nginx container image from local file, without hitting the server
kubectl set image -f path/to/file.yaml nginx=nginx:1.9.1 --local -o yaml
```

# kubectl set resources

## Synopsis

Specify compute resource requirements (CPU, memory) for any resource that defines a pod template. If a pod is successfully scheduled, it is guaranteed the amount of resource requested, but may burst up to its specified limits.

For each compute resource, if a limit is specified and a request is omitted, the request will default to the limit.

Possible resources include (case insensitive): Use "kubectl api-resources" for a complete list of supported resources..

```
kubectl set resources (-f FILENAME | TYPE NAME) ([--limits=LIMITS & --requests=REQUESTS]
```

## Examples

```
Set a deployments nginx container cpu limits to "200m" and memory to "512Mi"
kubectl set resources deployment nginx -c=nginx --limits=cpu=200m,memory=512Mi

Set the resource request and limits for all containers in nginx
kubectl set resources deployment nginx --limits=cpu=200m,memory=512Mi --requests=cpu=100m,memory=256Mi

Remove the resource requests for resources on containers in nginx
kubectl set resources deployment nginx --limits=cpu=0,memory=0 --requests=cpu=0,memory=0

Print the result (in yaml format) of updating nginx container limits from a local, without hitting the server
kubectl set resources -f path/to/file.yaml --limits=cpu=200m,memory=512Mi --local -o yaml
```

|                                                                                                                                                                                                               |  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <code>--all</code>                                                                                                                                                                                            |  |
| Select all resources, in the namespace of the specified resource types                                                                                                                                        |  |
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                      |  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                               |  |
| <code>-c, --containers string</code> Default: ""                                                                                                                                                              |  |
| The names of containers in the selected pod templates to change, all containers are selected by default - may use wildcards                                                                                   |  |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                                   |  |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.      |  |
| <code>--field-manager string</code> Default: "kubectl-set"                                                                                                                                                    |  |
| Name of the manager used to track field ownership.                                                                                                                                                            |  |
| <code>-f, --filename strings</code>                                                                                                                                                                           |  |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                           |  |
| <code>-h, --help</code>                                                                                                                                                                                       |  |
| help for resources                                                                                                                                                                                            |  |
| <code>-k, --kustomize string</code>                                                                                                                                                                           |  |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                          |  |
| <code>--limits string</code>                                                                                                                                                                                  |  |
| The resource requirement requests for this container. For example, 'cpu=100m,memory=256Mi'. Note that server side components may assign requests depending on the server configuration, such as limit ranges. |  |
| <code>--local</code>                                                                                                                                                                                          |  |
| If true, set resources will NOT contact api-server but run locally.                                                                                                                                           |  |
| <code>-o, --output string</code>                                                                                                                                                                              |  |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |
| -R, --recursive                                                                                                                                                                                                                                          |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                          |
| --requests string                                                                                                                                                                                                                                        |
| The resource requirement requests for this container. For example, 'cpu=100m,memory=256Mi'. Note that server side components may assign requests depending on the server configuration, such as limit ranges.                                            |
| -l, --selector string                                                                                                                                                                                                                                    |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectrl set selector

## Synopsis

Set the selector on a resource. Note that the new selector will overwrite the old selector if the resource had one prior to the invocation of 'set selector'.

A selector must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters. If --resource-version is specified, then updates will use this resource version, otherwise the existing resource-version will be used. Note: currently selectors can only be set on Service objects.

```
kubectrl set selector (-f FILENAME | TYPE NAME) EXPRESSIONS [--resource-version=version]
```

## Examples

```
Set the labels and selector before creating a deployment/service pair
kubectl create service clusterip my-svc --clusterip="None" -o yaml --dry-run=client | kubectl
set selector --local -f - 'environment=qa' -o yaml | kubectl create -f -
kubectl create deployment my-dep -o yaml --dry-run=client | kubectl label --local -f -
environment=qa -o yaml | kubectl create -f -
```

## Options

|                                                   |                                                                                                                                                                                                          |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --all                                             | Select all resources in the namespace of the specified resource types                                                                                                                                    |
| --allow-missing-template-keys    Default: true    | If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                          |
| --dry-run string[="unchanged"]    Default: "none" | Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-set"  | Name of the manager used to track field ownership.                                                                                                                                                       |
| -f, --filename strings                            | identifying the resource.                                                                                                                                                                                |
| -h, --help                                        | help for selector                                                                                                                                                                                        |
| --local                                           | If true, annotation will NOT contact api-server but run locally.                                                                                                                                         |
| -o, --output string                               | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |
| -R, --recursive    Default: true                  | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                          |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --resource-version string                                                                                                                                                                                                                                |
| If non-empty, the selectors update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.                                                                                               |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                           |                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                  | Default: "0"                                                                                                                                                                                      |
|                                           | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                       |                                                                                                                                                                                                   |
|                                           | The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration | Default: 1m0s                                                                                                                                                                                     |
|                                           | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string                | Default: "cadvisor"                                                                                                                                                                               |
|                                           | database name                                                                                                                                                                                     |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

## See Also

- [kubectl set](#) - Set specific features on objects

# kubectl set serviceaccount

## Synopsis

Update the service account of pod template resources.

Possible resources (case insensitive) can be:

replicationcontroller (rc), deployment (deploy), daemonset (ds), job, replicaset (rs), statefulset

```
kubectl set serviceaccount (-f FILENAME | TYPE NAME) SERVICE_ACCOUNT
```

## Examples

```
Set deployment nginx-deployment's service account to serviceaccount1
kubectl set serviceaccount deployment nginx-deployment serviceaccount1

Print the result (in YAML format) of updated nginx deployment with the service account
from local file, without hitting the API server
kubectl set sa -f nginx-deployment.yaml serviceaccount1 --local --dry-run=client -o yaml
```

## Options

|                                                                        |
|------------------------------------------------------------------------|
| --all                                                                  |
| Select all resources, in the namespace of the specified resource types |
| --allow-missing-template-keys    Default: true                         |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                          |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                 |
| --field-manager string    Default: "kubectl-set"                                                                                                                                                                                                         |
| Name of the manager used to track field ownership.                                                                                                                                                                                                       |
| -f, --filename strings                                                                                                                                                                                                                                   |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                                                                      |
| -h, --help                                                                                                                                                                                                                                               |
| help for serviceaccount                                                                                                                                                                                                                                  |
| -k, --kustomize string                                                                                                                                                                                                                                   |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                     |
| --local                                                                                                                                                                                                                                                  |
| If true, set serviceaccount will NOT contact api-server but run locally.                                                                                                                                                                                 |
| -o, --output string                                                                                                                                                                                                                                      |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |
| -R, --recursive                                                                                                                                                                                                                                          |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                          |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --as string                                                                                                                                                                                                                                              |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                           |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                            |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                           |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |

# kubect set subject

## Synopsis

Update the user, group, or service account in a role binding or cluster role binding.

```
kubect set subject (-f FILENAME | TYPE NAME) [--user=username] [--group=groupname] [--serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none]
```

## Examples

```
Update a cluster role binding for serviceaccount1
kubect set subject clusterrolebinding admin --serviceaccount=namespace:serviceaccount1

Update a role binding for user1, user2, and group1
kubect set subject rolebinding admin --user=user1 --user=user2 --group=group1

Print the result (in YAML format) of updating rolebinding subjects from a local, without hitting the server
kubect create rolebinding admin --role=admin --user=admin -o yaml --dry-run=client |
kubect set subject --local -f - --user=foo -o yaml
```

## Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --all                                                                                                                                                                                                    |
| Select all resources, in the namespace of the specified resource types                                                                                                                                   |
| --allow-missing-template-keys    Default: true                                                                                                                                                           |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                         |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-set"                                                                                                                                                         |
| Name of the manager used to track field ownership.                                                                                                                                                       |
| -f, --filename strings                                                                                                                                                                                   |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filename, directory, or URL to files the resource to update the subjects                                                                                                                                                                                 |
| --group strings                                                                                                                                                                                                                                          |
| Groups to bind to the role                                                                                                                                                                                                                               |
| -h, --help                                                                                                                                                                                                                                               |
| help for subject                                                                                                                                                                                                                                         |
| -k, --kustomize string                                                                                                                                                                                                                                   |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                     |
| --local                                                                                                                                                                                                                                                  |
| If true, set subject will NOT contact api-server but run locally.                                                                                                                                                                                        |
| -o, --output string                                                                                                                                                                                                                                      |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |
| -R, --recursive                                                                                                                                                                                                                                          |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                          |
| -l, --selector string                                                                                                                                                                                                                                    |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                               |
| --serviceaccount strings                                                                                                                                                                                                                                 |
| Service accounts to bind to the role                                                                                                                                                                                                                     |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --user strings                                                                                                                                                                                                                                           |
| Username to bind to the role                                                                                                                                                                                                                             |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                          |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                           |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                          |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                   |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                                                      |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |

| Password for basic authentication to the API server                                                                                                                                               |
| --profile string    Default: "none"                                                                                                                                                               |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cAdvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                              |

# kubectl taint

## Synopsis

Update the taints on one or more nodes.

- A taint consists of a key, value, and effect. As an argument here, it is expressed as key=value:effect.
- The key must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 253 characters.
- Optionally, the key can begin with a DNS subdomain prefix and a single '/', like example.com/my-app.
- The value is optional. If given, it must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters.
- The effect must be NoSchedule, PreferNoSchedule or NoExecute.
- Currently taint can only apply to node.

```
kubectl taint NODE NAME KEY_1=VAL_1:TAINT_EFFECT_1 ...
KEY_N=VAL_N:TAINT_EFFECT_N
```

## Examples

```
Update node 'foo' with a taint with key 'dedicated' and value 'special-user' and effect
'NoSchedule'
If a taint with that key and effect already exists, its value is replaced as specified
kubectl taint nodes foo dedicated=special-user:NoSchedule

Remove from node 'foo' the taint with key 'dedicated' and effect 'NoSchedule' if one exists
kubectl taint nodes foo dedicated:NoSchedule-

Remove from node 'foo' all the taints with key 'dedicated'
kubectl taint nodes foo dedicated-

Add a taint with key 'dedicated' on nodes having label myLabel=X
kubectl taint node -l myLabel=X dedicated=foo:PreferNoSchedule

Add to node 'foo' a taint with key 'bar' and no value
kubectl taint nodes foo bar:NoSchedule
```

## Options

|                                 |
|---------------------------------|
| --all                           |
| Select all nodes in the cluster |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                                                                                                                                                                                                                                                                                   |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                                                                                                                                                                                                                                                                          |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                          |
| <code>--validate string[="strict"]</code> Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise. |

"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

--as string

Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

--as-group strings

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.

--as-uid string

UID to impersonate for the operation.

--cache-dir string Default: "\$HOME/.kube/cache"

Default cache directory

--certificate-authority string

Path to a cert file for the certificate authority

--client-certificate string

Path to a client certificate file for TLS

--client-key string

Path to a client key file for TLS

--cloud-provider-gce-l7lb-src-cidrs cidrs Default: 130.211.0.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks

--cloud-provider-gce-lb-src-cidrs cidrs Default:  
130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks

--cluster string

The name of the kubeconfig cluster to use

--context string

The name of the kubeconfig context to use

--default-not-ready-toleration-seconds int Default: 300

|                                              | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                          |                                                                                                                                                                                                   |
|                                              | The address and port of the Kubernetes API server                                                                                                                                                 |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl top

## Synopsis

Display resource (CPU/memory) usage.

The top command allows you to see the resource consumption for nodes or pods.

This command requires Metrics Server to be correctly configured and working on the server.

kubectl top [flags]

## Options

|              |
|--------------|
| -h, --help   |
| help for top |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl top node

## Synopsis

Display resource (CPU/memory) usage of nodes.

The top-node command allows you to see the resource consumption of nodes.

```
kubectl top node [NAME | -l label]
```

# Examples

```
Show metrics for all nodes
kubectl top node

Show metrics for a given node
kubectl top node NODE_NAME
```

# Options

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h, --help                                                                                                                                                                 |
| help for node                                                                                                                                                              |
| --no-headers                                                                                                                                                               |
| If present, print output without headers                                                                                                                                   |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --show-capacity                                                                                                                                                            |
| Print node resources based on Capacity instead of Allocatable(default) of the nodes.                                                                                       |
| --sort-by string                                                                                                                                                           |
| If non-empty, sort nodes list using specified field. The field can be either 'cpu' or 'memory'.                                                                            |
| --use-protocol-buffers    Default: true                                                                                                                                    |
| Enables using protocol-buffers to access Metrics API.                                                                                                                      |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
|  | --match-server-version                                                                                                                                                                            |
|  | Require server version to match client version                                                                                                                                                    |
|  | -n, --namespace string                                                                                                                                                                            |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | --password string                                                                                                                                                                                 |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | --profile string   Default: "none"                                                                                                                                                                |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | --profile-output string   Default: "profile.pprof"                                                                                                                                                |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | --request-timeout string   Default: "0"                                                                                                                                                           |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | -s, --server string                                                                                                                                                                               |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
|  | database name                                                                                                                                                                                     |
|  | --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
|  | database host:port                                                                                                                                                                                |
|  | --storage-driver-password string   Default: "root"                                                                                                                                                |
|  | database password                                                                                                                                                                                 |
|  | --storage-driver-secure                                                                                                                                                                           |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl top](#) - Display resource (CPU/memory) usage

# kubectl top pod

## Synopsis

Display resource (CPU/memory) usage of pods.

The 'top pod' command allows you to see the resource consumption of pods.

Due to the metrics pipeline delay, they may be unavailable for a few minutes since pod creation.

```
kubecttl top pod [NAME | -l label]
```

## Examples

```
Show metrics for all pods in the default namespace
kubecttl top pod

Show metrics for all pods in the given namespace
kubecttl top pod --namespace=NAMESPACE

Show metrics for a given pod and its containers
kubecttl top pod POD_NAME --containers

Show metrics for the pods defined by label name=myLabel
kubecttl top pod -l name=myLabel
```

## Options

|                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -A, --all-namespaces                                                                                                                                                                    |
| If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.                                             |
| --containers                                                                                                                                                                            |
| If present, print usage of containers within a pod.                                                                                                                                     |
| --field-selector string                                                                                                                                                                 |
| Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type. |
| -h, --help                                                                                                                                                                              |
| help for pod                                                                                                                                                                            |
| --no-headers                                                                                                                                                                            |
| If present, print output without headers.                                                                                                                                               |
| -l, --selector string                                                                                                                                                                   |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.              |
| --sort-by string                                                                                                                                                                        |

|                                                                                                |
|------------------------------------------------------------------------------------------------|
| If non-empty, sort pods list using specified field. The field can be either 'cpu' or 'memory'. |
| --sum                                                                                          |
| Print the sum of the resource usage                                                            |
| --use-protocol-buffers    Default: true                                                        |
| Enables using protocol-buffers to access Metrics API.                                          |

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |

# kubectl uncordon

## Synopsis

Mark node as schedulable.

kubectl uncordon NODE

## Examples

```
Mark node "foo" as schedulable
kubectl uncordon foo
```

## Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| -h, --help                                                                                                                                                                                               |
| help for uncordon                                                                                                                                                                                        |
| -l, --selector string                                                                                                                                                                                    |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                               |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                          |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                           |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |

| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                   |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |

|                                                                                                                                                                                                   |                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| --default-unreachable-toleration-seconds int                                                                                                                                                      | Default: 300             |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |                          |
| --disable-compression                                                                                                                                                                             |                          |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |                          |
| --insecure-skip-tls-verify                                                                                                                                                                        |                          |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |                          |
| --kubeconfig string                                                                                                                                                                               |                          |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |                          |
| --match-server-version                                                                                                                                                                            |                          |
| Require server version to match client version                                                                                                                                                    |                          |
| -n, --namespace string                                                                                                                                                                            |                          |
| If present, the namespace scope for this CLI request                                                                                                                                              |                          |
| --password string                                                                                                                                                                                 |                          |
| Password for basic authentication to the API server                                                                                                                                               |                          |
| --profile string                                                                                                                                                                                  | Default: "none"          |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |                          |
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof" |
| Name of the file to write the profile to                                                                                                                                                          |                          |
| --request-timeout string                                                                                                                                                                          | Default: "0"             |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                          |
| -s, --server string                                                                                                                                                                               |                          |
| The address and port of the Kubernetes API server                                                                                                                                                 |                          |
| --storage-driver-buffer-duration duration                                                                                                                                                         | Default: 1m0s            |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

Treat warnings received from the server as errors and exit with a non-zero exit code

# kubectl version

## Synopsis

Print the client and server version information for the current context.

```
kubectl version [flags]
```

## Examples

```
Print the client and server versions for the current context
kubectl version
```

## Options

|                                                          |
|----------------------------------------------------------|
| --client                                                 |
| If true, shows client version only (no server required). |
| -h, --help                                               |
| help for version                                         |
| -o, --output string                                      |
| One of 'yaml' or 'json'.                                 |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl wait

## Synopsis

Experimental: Wait for a specific condition on one or many resources.

The command takes multiple resources and waits until the specified condition is seen in the Status field of every given resource.

Alternatively, the command can wait for the given set of resources to be deleted by providing the "delete" keyword as the value to the --for flag.

A successful message will be printed to stdout indicating when the specified condition has been met. You can use -o option to change to output destination.

```
kubectl wait ([-f FILENAME] | resource.group/resource.name | resource.group [--label label | --all])
[--for=delete|--for condition=available|--for=jsonpath='{.}'[=value]]
```

## Examples

```
Wait for the pod "busybox1" to contain the status condition of type "Ready"
kubectl wait --for=condition=Ready pod/busybox1

The default value of status condition is true; you can wait for other targets after an equal
delimiter (compared after Unicode simple case folding, which is a more general form of case-
insensitivity)
kubectl wait --for=condition=Ready=false pod/busybox1

Wait for the pod "busybox1" to contain the status phase to be "Running"
kubectl wait --for=jsonpath='{.status.phase}'=Running pod/busybox1

Wait for pod "busybox1" to be Ready
kubectl wait --for=jsonpath='{.status.conditions[?(@.type=="Ready")].status}=True' pod/
busybox1

Wait for the service "loadbalancer" to have ingress.
kubectl wait --for=jsonpath='{.status.loadBalancer.ingress}' service/loadbalancer

Wait for the pod "busybox1" to be deleted, with a timeout of 60s, after having issued the
"delete" command
kubectl delete pod/busybox1
kubectl wait --for=delete pod/busybox1 --timeout=60s
```

## Options

|                                                                       |
|-----------------------------------------------------------------------|
| --all                                                                 |
| Select all resources in the namespace of the specified resource types |
| -A, --all-namespaces                                                  |

|  |                                                                                                                                                                                                                                                                                            |
|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.                                                                                                                                                |
|  | --allow-missing-template-keys    Default: true                                                                                                                                                                                                                                             |
|  | If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                                                                                                            |
|  | --field-selector string                                                                                                                                                                                                                                                                    |
|  | Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type.                                                                                                    |
|  | -f, --filename strings                                                                                                                                                                                                                                                                     |
|  | identifying the resource.                                                                                                                                                                                                                                                                  |
|  | --for string                                                                                                                                                                                                                                                                               |
|  | The condition to wait on: [delete condition=condition-name[=condition-value] jsonpath='{JSONPath expression}'=[JSONPath value]]. The default condition-value is true. Condition values are compared after Unicode simple case folding, which is a more general form of case-insensitivity. |
|  | -h, --help                                                                                                                                                                                                                                                                                 |
|  | help for wait                                                                                                                                                                                                                                                                              |
|  | --local                                                                                                                                                                                                                                                                                    |
|  | If true, annotation will NOT contact api-server but run locally.                                                                                                                                                                                                                           |
|  | -o, --output string                                                                                                                                                                                                                                                                        |
|  | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                                                               |
|  | -R, --recursive    Default: true                                                                                                                                                                                                                                                           |
|  | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                                                            |
|  | -l, --selector string                                                                                                                                                                                                                                                                      |
|  | Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2)                                                                                                                                                                                        |
|  | --show-managed-fields                                                                                                                                                                                                                                                                      |
|  | If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                              |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --timeout duration    Default: 30s                                                                                                                                                                                                                        |
| The length of time to wait before giving up. Zero means check once and don't wait, negative means wait for a week.                                                                                                                                        |

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                             |

## Options

|                                                                                               |
|-----------------------------------------------------------------------------------------------|
| --add-dir-header                                                                              |
| If true, adds the file directory to the header of the log messages                            |
| --alsologtostderr                                                                             |
| log to standard error as well as files                                                        |
| --as string                                                                                   |
| Username to impersonate for the operation                                                     |
| --as-group stringArray                                                                        |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups. |
| --azure-container-registry-config string                                                      |
| Path to the file containing Azure container registry configuration information.               |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                            |
| Default cache directory                                                                       |
| --certificate-authority string                                                                |
| Path to a cert file for the certificate authority                                             |
| --client-certificate string                                                                   |
| Path to a client certificate file for TLS                                                     |
| --client-key string                                                                           |
| Path to a client key file for TLS                                                             |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|

| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --log-backtrace-at traceLocation    Default: :0                                                                                                                 |
| when logging hits line file:N, emit a stack trace                                                                                                               |
| --log-dir string                                                                                                                                                |
| If non-empty, write log files in this directory                                                                                                                 |
| --log-file string                                                                                                                                               |
| If non-empty, use this log file                                                                                                                                 |
| --log-file-max-size uint    Default: 1800                                                                                                                       |
| Defines the maximum size a log file can grow to. Unit is megabytes. If the value is 0, the maximum file size is unlimited.                                      |
| --log-flush-frequency duration    Default: 5s                                                                                                                   |
| Maximum number of seconds between log flushes                                                                                                                   |
| --logtostderr    Default: true                                                                                                                                  |
| log to standard error instead of files                                                                                                                          |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --one-output                                                                                                                                                    |
| If true, only write logs to their native severity level (vs also writing to each lower severity level)                                                          |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |

|                                                                                                                                                                                                   |                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof" |
| Name of the file to write the profile to                                                                                                                                                          |                          |
| --request-timeout string                                                                                                                                                                          | Default: "0"             |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                          |
| -s, --server string                                                                                                                                                                               |                          |
| The address and port of the Kubernetes API server                                                                                                                                                 |                          |
| --skip-headers                                                                                                                                                                                    |                          |
| If true, avoid header prefixes in the log messages                                                                                                                                                |                          |
| --skip-log-headers                                                                                                                                                                                |                          |
| If true, avoid headers when opening log files                                                                                                                                                     |                          |
| --stderrthreshold severity                                                                                                                                                                        | Default: 2               |
| logs at or above this threshold go to stderr                                                                                                                                                      |                          |
| --tls-server-name string                                                                                                                                                                          |                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |                          |
| --token string                                                                                                                                                                                    |                          |
| Bearer token for authentication to the API server                                                                                                                                                 |                          |
| --user string                                                                                                                                                                                     |                          |
| The name of the kubeconfig user to use                                                                                                                                                            |                          |
| --username string                                                                                                                                                                                 |                          |
| Username for basic authentication to the API server                                                                                                                                               |                          |
| -v, --v Level                                                                                                                                                                                     |                          |
| number for the log level verbosity                                                                                                                                                                |                          |
| --version version[=true]                                                                                                                                                                          |                          |
| Print version information and quit                                                                                                                                                                |                          |
| --vmodule moduleSpec                                                                                                                                                                              |                          |
| comma-separated list of pattern=N settings for file-filtered logging                                                                                                                              |                          |
| --warnings-as-errors                                                                                                                                                                              |                          |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                                                                                              |                          |

## Environment variables

|                                                                                                                                                |  |
|------------------------------------------------------------------------------------------------------------------------------------------------|--|
| KUBECONFIG                                                                                                                                     |  |
| Path to the kubectl configuration ("kubeconfig") file. Default: "\$HOME/.kube/config"                                                          |  |
| KUBECTL_COMMAND_HEADERS                                                                                                                        |  |
| When set to false, turns off extra HTTP headers detailing invoked kubectl command (Kubernetes version v1.22 or later)                          |  |
| KUBECTL_DEBUG_CUSTOM_PROFILE                                                                                                                   |  |
| When set to true, custom flag will be enabled in kubectl debug. This flag is used to customize the pre-defined profiles.                       |  |
| KUBECTL_EXPLAIN_OPENAPIV3                                                                                                                      |  |
| Toggles whether calls to `kubectl explain` use the new OpenAPIv3 data source available. OpenAPIv3 is enabled by default since Kubernetes 1.24. |  |
| KUBECTL_ENABLE_CMD_SHADOW                                                                                                                      |  |

|                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| When set to true, external plugins can be used as subcommands for builtin commands if subcommand does not exist. In alpha stage, this feature can only be used for create command(e.g. <code>kubectl create networkpolicy</code> ).                         |
| KUBECTL_PORT_FORWARD_WEBSOCKETS                                                                                                                                                                                                                             |
| When set to true, the <code>kubectl port-forward</code> command will attempt to stream using the websockets protocol. If the upgrade to websockets fails, the commands will fallback to use the current SPDY protocol.                                      |
| KUBECTL_REMOTE_COMMAND_WEBSOCKETS                                                                                                                                                                                                                           |
| When set to true, the <code>kubectl exec</code> , <code>cp</code> , and <code>attach</code> commands will attempt to stream using the websockets protocol. If the upgrade to websockets fails, the commands will fallback to use the current SPDY protocol. |

## See Also

- [kubectl annotate](#) - Update the annotations on a resource
- [kubectl api-resources](#) - Print the supported API resources on the server
- [kubectl api-versions](#) - Print the supported API versions on the server, in the form of "group/version"
- [kubectl apply](#) - Apply a configuration to a resource by filename or stdin
- [kubectl attach](#) - Attach to a running container
- [kubectl auth](#) - Inspect authorization
- [kubectl autoscale](#) - Auto-scale a Deployment, ReplicaSet, or ReplicationController
- [kubectl certificate](#) - Modify certificate resources.
- [kubectl cluster-info](#) - Display cluster info
- [kubectl completion](#) - Output shell completion code for the specified shell (bash or zsh)
- [kubectl config](#) - Modify kubeconfig files
- [kubectl cordon](#) - Mark node as unschedulable
- [kubectl cp](#) - Copy files and directories to and from containers.
- [kubectl create](#) - Create a resource from a file or from stdin.
- [kubectl debug](#) - Create debugging sessions for troubleshooting workloads and nodes
- [kubectl delete](#) - Delete resources by filenames, stdin, resources and names, or by resources and label selector
- [kubectl describe](#) - Show details of a specific resource or group of resources
- [kubectl diff](#) - Diff live version against would-be applied version
- [kubectl drain](#) - Drain node in preparation for maintenance
- [kubectl edit](#) - Edit a resource on the server
- [kubectl events](#) - List events
- [kubectl exec](#) - Execute a command in a container
- [kubectl explain](#) - Documentation of resources
- [kubectl expose](#) - Take a replication controller, service, deployment or pod and expose it as a new Kubernetes Service
- [kubectl get](#) - Display one or many resources
- [kubectl kustomize](#) - Build a kustomization target from a directory or a remote url.
- [kubectl label](#) - Update the labels on a resource
- [kubectl logs](#) - Print the logs for a container in a pod
- [kubectl options](#) - Print the list of flags inherited by all commands
- [kubectl patch](#) - Update field(s) of a resource
- [kubectl plugin](#) - Provides utilities for interacting with plugins.
- [kubectl port-forward](#) - Forward one or more local ports to a pod
- [kubectl proxy](#) - Run a proxy to the Kubernetes API server
- [kubectl replace](#) - Replace a resource by filename or stdin

- [kubectl rollout](#) - Manage the rollout of a resource
- [kubectl run](#) - Run a particular image on the cluster
- [kubectl scale](#) - Set a new size for a Deployment, ReplicaSet or Replication Controller
- [kubectl set](#) - Set specific features on objects
- [kubectl taint](#) - Update the taints on one or more nodes
- [kubectl top](#) - Display Resource (CPU/Memory/Storage) usage.
- [kubectl uncordon](#) - Mark node as schedulable
- [kubectl version](#) - Print the client and server version information
- [kubectl wait](#) - Experimental: Wait for a specific condition on one or many resources.

## JSONPath Support

Kubectl supports JSONPath template.

JSONPath template is composed of JSONPath expressions enclosed by curly braces {}. Kubectl uses JSONPath expressions to filter on specific fields in the JSON object and format the output. In addition to the original JSONPath template syntax, the following functions and syntax are valid:

1. Use double quotes to quote text inside JSONPath expressions.
2. Use the range, end operators to iterate lists.
3. Use negative slice indices to step backwards through a list. Negative indices do not "wrap around" a list and are valid as long as `-index + listLength >= 0`.

### Note:

- The \$ operator is optional since the expression always starts from the root object by default.
- The result object is printed as its String() function.

Given the JSON input:

```
{
 "kind": "List",
 "items": [
 {
 "kind": "None",
 "metadata": {
 "name": "127.0.0.1",
 "labels": {
 "kubernetes.io/hostname": "127.0.0.1"
 }
 }
 },
 {
 "status": {
 "capacity": { "cpu": "4" },
 "addresses": [{ "type": "LegacyHostIP", "address": "127.0.0.1" }]
 }
 },
 {
 "kind": "None",
 "metadata": { "name": "127.0.0.2" },

```

```

 "status":{
 "capacity":{"cpu":"8"},
 "addresses":[
 {"type": "LegacyHostIP", "address":"127.0.0.2"},
 {"type": "another", "address":"127.0.0.3"}
]
 }
 },
 "users":[
 {
 "name": "myself",
 "user": {}
 },
 {
 "name": "e2e",
 "user": {"username": "admin", "password": "secret"}
 }
]
}

```

| Function         | Description                  | Example                                                    | Result                                                   |
|------------------|------------------------------|------------------------------------------------------------|----------------------------------------------------------|
| text             | the plain text               | kind is {kind}                                             | kind is List                                             |
| @                | the current object           | {@}                                                        | the same as input                                        |
| . or []          | child operator               | {kind}, {[kind']} or {[name.type']}                        | List                                                     |
| ..               | recursive descent            | {..name}                                                   | 127.0.0.1 127.0.0.2<br>myself e2e                        |
| *                | wildcard. Get all objects    | {items[*].metadata.name}                                   | [127.0.0.1<br>127.0.0.2]                                 |
| [start:end:step] | subscript operator           | {users[0].name}                                            | myself                                                   |
| [,]              | union operator               | {items[*]['metadata.name', 'status.capacity']}             | 127.0.0.1 127.0.0.2<br>map[cpu:4]<br>map[cpu:8]          |
| ?()              | filter                       | {users[?(@.name=="e2e")].user.password}                    | secret                                                   |
| range, end       | iterate list                 | {range items[*]}[{metadata.name}, {status.capacity}] {end} | [127.0.0.1,<br>map[cpu:4]]<br>[127.0.0.2,<br>map[cpu:8]] |
| "                | quote interpreted string     | {range items[*]}{metadata.name}{\t}{end}                   | 127.0.0.1 127.0.0.2                                      |
| \                | escape termination character | {items[0].metadata.labels.kubernetes.io/hostname}          | 127.0.0.1                                                |

Examples using kubectl and JSONPath expressions:

```

kubectl get pods -o json
kubectl get pods -o=jsonpath='{@}'

```

```
kubectl get pods -o=jsonpath='{.items[0]}'
kubectl get pods -o=jsonpath='{.items[0].metadata.name}'
kubectl get pods -o=jsonpath="{.items[*]['metadata.name', 'status.capacity']}"
kubectl get pods -o=jsonpath='{range .items[*]}{.metadata.name}{\t}{.status.startTime}{\n}{end}'
kubectl get pods -o=jsonpath='{.items[0].metadata.labels.kubernetes\.io/hostname}'
```

#### Note:

On Windows, you must *double* quote any JSONPath template that contains spaces (not single quote as shown above for bash). This in turn means that you must use a single quote or escaped double quote around any literals in the template. For example:

```
kubectl get pods -o=jsonpath="{range .items[*]}{.metadata.name}{\t}{.status.startTime}{\n}{end}"
kubectl get pods -o=jsonpath="{range .items[*]}{.metadata.name}{\"\\t\"}{.status.startTime}{\\\"\\n\\\"}{end}"
```

#### Note:

JSONPath regular expressions are not supported. If you want to match using regular expressions, you can use a tool such as jq.

```
kubectl does not support regular expressions for JSONpath output
The following command does not work
kubectl get pods -o jsonpath='{.items[?(@.metadata.name=~/^test$/)].metadata.name}'

The following command achieves the desired result
kubectl get pods -o json | jq -r '.items[] | select(.metadata.name | test("test-")).metadata.name'
```

## kubectl for Docker Users

You can use the Kubernetes command line tool kubectl to interact with the API Server. Using kubectl is straightforward if you are familiar with the Docker command line tool. However, there are a few differences between the Docker commands and the kubectl commands. The following sections show a Docker sub-command and describe the equivalent kubectl command.

### docker run

To run an nginx Deployment and expose the Deployment, see [kubectl create deployment](#).  
docker:

```
docker run -d --restart=always -e DOMAIN=cluster --name nginx-app -p 80:80 nginx
```

```
55c103fa129692154a7652490236fee9be47d70a8dd562281ae7d2f9a339a6db
```

```
docker ps
```

| CONTAINER ID | IMAGE | COMMAND | CREATED |
|--------------|-------|---------|---------|
| STATUS       | PORTS | NAMES   |         |

```
55c103fa1296 nginx "nginx -g 'daemon of..." 9 seconds ago Up 9 seconds
0.0.0.0:80->80/tcp nginx-app
```

kubectl:

```
start the pod running nginx
kubectl create deployment --image=nginx nginx-app
```

```
deployment.apps/nginx-app created
```

```
add env to nginx-app
kubectl set env deployment/nginx-app DOMAIN=cluster
```

```
deployment.apps/nginx-app env updated
```

### Note:

kubectl commands print the type and name of the resource created or mutated, which can then be used in subsequent commands. You can expose a new Service after a Deployment is created.

```
expose a port through with a service
kubectl expose deployment nginx-app --port=80 --name=nginx-http
```

```
service "nginx-http" exposed
```

By using kubectl, you can create a [Deployment](#) to ensure that N pods are running nginx, where N is the number of replicas stated in the spec and defaults to 1. You can also create a [service](#) with a selector that matches the pod labels. For more information, see [Use a Service to Access an Application in a Cluster](#).

By default images run in the background, similar to `docker run -d ...`. To run things in the foreground, use [kubectl run](#) to create pod:

```
kubectl run [-i] [--tty] --attach <name> --image=<image>
```

Unlike `docker run ...`, if you specify `--attach`, then you attach stdin, stdout and stderr. You cannot control which streams are attached (`docker -a ...`). To detach from the container, you can type the escape sequence `Ctrl+P` followed by `Ctrl+Q`.

## docker ps

To list what is currently running, see [kubectl get](#).

docker:

```
docker ps -a
```

| CONTAINER ID | IMAGE              | COMMAND                  | CREATED              |
|--------------|--------------------|--------------------------|----------------------|
| STATUS       | PORTS              | NAMES                    |                      |
| 14636241935f | ubuntu:16.04       | "echo test"              | 5 seconds ago        |
| ago          | cocky_fermi        |                          | Exited (0) 5 seconds |
| 55c103fa1296 | nginx              | "nginx -g 'daemon of..." | About a minute ago   |
| minute       | 0.0.0.0:80->80/tcp | nginx-app                | Up About a           |

kubectl:

```
kubectl get po
```

| NAME                      | READY | STATUS    | RESTARTS | AGE |
|---------------------------|-------|-----------|----------|-----|
| nginx-app-8df569cb7-4gd89 | 1/1   | Running   | 0        | 3m  |
| ubuntu                    | 0/1   | Completed | 0        | 20s |

## docker attach

To attach a process that is already running in a container, see [kubectl attach](#).

docker:

```
docker ps
```

| CONTAINER ID       | IMAGE     | COMMAND                   | CREATED       |
|--------------------|-----------|---------------------------|---------------|
| 55c103fa1296       | nginx     | "nginx -g 'daemon of...'" | 5 minutes ago |
| 0.0.0.0:80->80/tcp | nginx-app |                           | Up 5 minutes  |

```
docker attach 55c103fa1296
```

...

kubectl:

```
kubectl get pods
```

| NAME            | READY | STATUS  | RESTARTS | AGE |
|-----------------|-------|---------|----------|-----|
| nginx-app-5jyvm | 1/1   | Running | 0        | 10m |

```
kubectl attach -it nginx-app-5jyvm
```

...

To detach from the container, you can type the escape sequence Ctrl+P followed by Ctrl+Q.

## docker exec

To execute a command in a container, see [kubectl exec](#).

docker:

```
docker ps
```

| CONTAINER ID       | IMAGE     | COMMAND                   | CREATED       |
|--------------------|-----------|---------------------------|---------------|
| 55c103fa1296       | nginx     | "nginx -g 'daemon of...'" | 6 minutes ago |
| 0.0.0.0:80->80/tcp | nginx-app |                           | Up 6 minutes  |

```
docker exec 55c103fa1296 cat /etc/hostname
```

```
55c103fa1296
```

kubectl:

```
kubectl get po
```

| NAME            | READY | STATUS  | RESTARTS | AGE |
|-----------------|-------|---------|----------|-----|
| nginx-app-5jyvm | 1/1   | Running | 0        | 10m |

```
kubectl exec nginx-app-5jyvm -- cat /etc/hostname
```

```
nginx-app-5jyvm
```

To use interactive commands.

docker:

```
docker exec -ti 55c103fa1296 /bin/sh
exit
```

kubectl:

```
kubectl exec -ti nginx-app-5jyvm -- /bin/sh
exit
```

For more information, see [Get a Shell to a Running Container](#).

## docker logs

To follow stdout/stderr of a process that is running, see [kubectl logs](#).

docker:

```
docker logs -f a9e
```

```
192.168.9.1 - - [14/Jul/2015:01:04:02 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.35.0" "-"
192.168.9.1 - - [14/Jul/2015:01:04:03 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.35.0" "-"
```

kubectl:

```
kubectl logs -f nginx-app-zibvs
```

```
10.240.63.110 - - [14/Jul/2015:01:09:01 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.26.0" "-"
10.240.63.110 - - [14/Jul/2015:01:09:02 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.26.0" "-"
```

There is a slight difference between pods and containers; by default pods do not terminate if their processes exit. Instead the pods restart the process. This is similar to the docker run option `--restart=always` with one major difference. In docker, the output for each invocation of the process is concatenated, but for Kubernetes, each invocation is separate. To see the output from a previous run in Kubernetes, do this:

```
kubectl logs --previous nginx-app-zibvs
```

```
10.240.63.110 - - [14/Jul/2015:01:09:01 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.26.0" "-"
10.240.63.110 - - [14/Jul/2015:01:09:02 +0000] "GET / HTTP/1.1" 200 612 "-" "curl/7.26.0" "-"
```

For more information, see [Logging Architecture](#).

## docker stop and docker rm

To stop and delete a running process, see [kubectl delete](#).

docker:

```
docker ps
```

| CONTAINER ID        | IMAGE     | COMMAND               | CREATED      | STATUS      |
|---------------------|-----------|-----------------------|--------------|-------------|
| PORTS               | NAMES     |                       |              |             |
| a9ec34d98787        | nginx     | "nginx -g 'daemon of" | 22 hours ago | Up 22 hours |
| 0.0.0.0:80->80/tcp, | nginx-app |                       |              |             |

```
docker stop a9ec34d98787
```

```
a9ec34d98787
```

```
docker rm a9ec34d98787
```

```
a9ec34d98787
```

kubectl:

```
kubectl get deployment nginx-app
```

| NAME      | READY | UP-TO-DATE | AVAILABLE | AGE |
|-----------|-------|------------|-----------|-----|
| nginx-app | 1/1   | 1          | 1         | 2m  |

```
kubectl get po -l app=nginx-app
```

| NAME                       | READY | STATUS  | RESTARTS | AGE |
|----------------------------|-------|---------|----------|-----|
| nginx-app-2883164633-aklf7 | 1/1   | Running | 0        | 2m  |

```
kubectl delete deployment nginx-app
```

```
deployment "nginx-app" deleted
```

```
kubectl get po -l app=nginx-app
```

```
Return nothing
```

### Note:

When you use kubectl, you don't delete the pod directly. You have to first delete the Deployment that owns the pod. If you delete the pod directly, the Deployment recreates the pod.

## docker login

There is no direct analog of docker login in kubectl. If you are interested in using Kubernetes with a private registry, see [Using a Private Registry](#).

## docker version

To get the version of client and server, see [kubectl version](#).

docker:

```
docker version
```

```
Client version: 1.7.0
Client API version: 1.19
Go version (client): go1.4.2
Git commit (client): 0baf609
OS/Arch (client): linux/amd64
Server version: 1.7.0
Server API version: 1.19
Go version (server): go1.4.2
Git commit (server): 0baf609
OS/Arch (server): linux/amd64
```

kubectl:

```
kubectl version
```

```

InfluxDB is running at https://203.0.113.141/api/v1/namespaces/kube-system/services/monitoring-influxdb/proxy
```

## kubectl Usage Conventions

Recommended usage conventions for kubectl.

### Using kubectl in Reusable Scripts

For a stable output in a script:

- Request one of the machine-oriented output forms, such as `-o name`, `-o json`, `-o yaml`, `-o go-template`, or `-o jsonpath`.
- Fully-qualify the version. For example, `jobs.v1.batch/myjob`. This will ensure that kubectl does not use its default version that can change over time.
- Don't rely on context, preferences, or other implicit states.

### Subresources

- You can use the `--subresource` beta flag for kubectl commands like `get`, `patch`, `edit` and `replace` to fetch and update subresources for all resources that support them. Currently, only the status and scale subresources are supported.
  - For kubectl `edit`, the scale subresource is not supported. If you use `--subresource` with kubectl `edit` and specify scale as the subresource, the command will error out.
- The API contract against a subresource is identical to a full resource. While updating the status subresource to a new value, keep in mind that the subresource could be potentially reconciled by a controller to a different value.

# Best Practices

## kubectl run

For `kubectl run` to satisfy infrastructure as code:

- Tag the image with a version-specific tag and don't move that tag to a new version. For example, use `:v1234`, `v1.2.3`, `r03062016-1-4`, rather than `:latest` (For more information, see [Best Practices for Configuration](#)).
- Check in the script for an image that is heavily parameterized.
- Switch to configuration files checked into source control for features that are needed, but not expressible via `kubectl run` flags.

You can use the `--dry-run=client` flag to preview the object that would be sent to your cluster, without really submitting it.

## kubectl apply

- You can use `kubectl apply` to create or update resources. For more information about using `kubectl apply` to update resources, see [Kubectl Book](#).

# Feature Gates

This page contains an overview of the various feature gates an administrator can specify on different Kubernetes components.

See [feature stages](#) for an explanation of the stages for a feature.

# Overview

Feature gates are a set of key=value pairs that describe Kubernetes features. You can turn these features on or off using the `--feature-gates` command line flag on each Kubernetes component.

Each Kubernetes component lets you enable or disable a set of feature gates that are relevant to that component. Use `-h` flag to see a full set of feature gates for all components. To set feature gates for a component, such as kubelet, use the `--feature-gates` flag assigned to a list of feature pairs:

```
--feature-gates=...,GracefulNodeShutdown=true
```

The following tables are a summary of the feature gates that you can set on different Kubernetes components.

- The "Since" column contains the Kubernetes release when a feature is introduced or its release stage is changed.
- The "Until" column, if not empty, contains the last Kubernetes release in which you can still use a feature gate.
- If a feature is in the Alpha or Beta state, you can find the feature listed in the [Alpha/Beta feature gate table](#).
- If a feature is stable you can find all stages for that feature listed in the [Graduated/Deprecated feature gate table](#).
- The [Graduated/Deprecated feature gate table](#) also lists deprecated and withdrawn features.

## Note:

For a reference to old feature gates that are removed, please refer to [feature gates removed](#).

## Feature gates for Alpha or Beta features

Feature gates for features in Alpha or Beta states

| Feature                       | Default | Stage | Since | Until |
|-------------------------------|---------|-------|-------|-------|
| AnyVolumeDataSource           | false   | Alpha | 1.18  | 1.23  |
| AnyVolumeDataSource           | true    | Beta  | 1.24  | –     |
| APIResponseCompression        | false   | Alpha | 1.7   | 1.15  |
| APIResponseCompression        | true    | Beta  | 1.16  | –     |
| APIServerIdentity             | false   | Alpha | 1.20  | 1.25  |
| APIServerIdentity             | true    | Beta  | 1.26  | –     |
| APIServerTracing              | false   | Alpha | 1.22  | 1.26  |
| APIServerTracing              | true    | Beta  | 1.27  | –     |
| AppArmor                      | true    | Beta  | 1.4   | –     |
| CloudControllerManagerWebhook | false   | Alpha | 1.27  | –     |
| ClusterTrustBundle            | false   | Alpha | 1.27  | –     |
| ClusterTrustBundleProjection  | false   | Alpha | 1.29  | –     |
| ComponentSLIs                 | false   | Alpha | 1.26  | 1.26  |
| ComponentSLIs                 | true    | Beta  | 1.27  | –     |
| ConsistentListFromCache       | false   | Alpha | 1.28  | –     |

| Feature                                | Default | Stage | Since | Until |
|----------------------------------------|---------|-------|-------|-------|
| ContainerCheckpoint                    | false   | Alpha | 1.25  | –     |

# Using a feature

## Feature stages

A feature can be in *Alpha*, *Beta* or *GA* stage. An *Alpha* feature means:

- Disabled by default.
- Might be buggy. Enabling the feature may expose bugs.
- Support for feature may be dropped at any time without notice.
- The API may change in incompatible ways in a later software release without notice.
- Recommended for use only in short-lived testing clusters, due to increased risk of bugs and lack of long-term support.

A *Beta* feature means:

- Usually enabled by default. Beta API groups are [disabled by default](#).
- The feature is well tested. Enabling the feature is considered safe.
- Support for the overall feature will not be dropped, though details may change.
- The schema and/or semantics of objects may change in incompatible ways in a subsequent beta or stable release. When this happens, we will provide instructions for migrating to the next version. This may require deleting, editing, and re-creating API objects. The editing process may require some thought. This may require downtime for applications that rely on the feature.
- Recommended for only non-business-critical uses because of potential for incompatible changes in subsequent releases. If you have multiple clusters that can be upgraded independently, you may be able to relax this restriction.

### Note:

Please do try *Beta* features and give feedback on them! After they exit beta, it may not be practical for us to make more changes.

A *General Availability* (GA) feature is also referred to as a *stable* feature. It means:

- The feature is always enabled; you cannot disable it.
- The corresponding feature gate is no longer needed.
- Stable versions of features will appear in released software for many subsequent versions.

## List of feature gates

Each feature gate is designed for enabling/disabling a specific feature.

- AdmissionWebhookMatchConditions: Enable [match conditions](#) on mutating & validating admission webhooks.
- AggregatedDiscoveryEndpoint: Enable a single HTTP endpoint `/discovery/<version>` which supports native HTTP caching with ETags containing all APIResources known to the API server.
- AllowServiceLBStatusOnNonLB: Enables `.status.ingress.loadBalancer` to be set on Services of types other than LoadBalancer.

- AnyVolumeDataSource: Enable use of any custom resource as the DataSource of a [PVC](#).
- 
- APIListChunking: Enable the API clients to retrieve (LIST or GET) resources from API server in chunks.
- APIPriorityAndFairness: Enable managing request concurrency with prioritization and fairness at each server. (Renamed from RequestManagement)
- APIResponseCompression: Compress the API responses for LIST or GET requests.
- APIServerIdentity: Assign each API server an ID in a cluster, using a [Lease](#).
- APIServerTracing: Add support for distributed tracing in the API server. See [Traces for Kubernetes System Components](#) for more details.
- AppArmor: Enable use of AppArmor mandatory access control for Pods running on Linux nodes. See [AppArmor Tutorial](#) for more details.
- CloudControllerManagerWebhook: Enable webhooks in cloud controller manager.
- CloudDualStackNodeIPs: Enables dual-stack kubelet --node-ip with external cloud providers. See [Configure IPv4/IPv6 dual-stack](#) for more details.
- ClusterTrustBundle: Enable ClusterTrustBundle objects and kubelet integration.
- ClusterTrustBundleProjection: [clusterTrustBundle projected volume sources](#).
- ComponentSLIs: Enable the /metrics/slis endpoint on Kubernetes components like kubelet, kube-scheduler, kube-proxy, kube-controller-manager, cloud-controller-manager allowing you to scrape health check metrics.
- ConsistentHTTPGetHandlers: Normalize HTTP get URL and Header passing for lifecycle handlers with probes.
- ConsistentListFromCache: Allow the API server to serve consistent lists from cache.
- ContainerCheckpoint: Enables the kubelet checkpoint API. See [Kubelet Checkpoint API](#) for more details.
- ContextualLogging: Enables extra details in log output of Kubernetes components that support contextual logging.
- CPUManager: Enable container level CPU affinity support, see [CPU Management Policies](#).
- CPUManagerPolicyAlphaOptions: This allows fine-tuning of CPUManager policies, experimental, Alpha-quality options This feature gate guards *a group* of CPUManager options whose quality level is alpha. This feature gate will never graduate to beta or stable.
- CPUManagerPolicyBetaOptions: This allows fine-tuning of CPUManager policies, experimental, Beta-quality options This feature gate guards *a group* of CPUManager options whose quality level is beta. This feature gate will never graduate to stable.
- CPUManagerPolicyOptions: Allow fine-tuning of CPUManager policies.

- **CRDValidationRatcheting**: Enable updates to custom resources to contain violations of their OpenAPI schema if the offending portions of the resource update did not change. See [Validation Ratcheting](#) for more details.
- **CronJobsScheduledAnnotation**: Set the scheduled job time as an [annotation](#) on Jobs that were created on behalf of a CronJob.
- **CrossNamespaceVolumeDataSource**: Enable the usage of cross namespace volume data source to allow you to specify a source namespace in the dataSourceRef field of a PersistentVolumeClaim.
- **CSIMigrationPortworx**: Enables shims and translation logic to route volume operations from the Portworx in-tree plugin to Portworx CSI plugin. Requires Portworx CSI driver to be installed and configured in the cluster.
- **CSIMigrationRBD**: Enables shims and translation logic to route volume operations from the RBD in-tree plugin to Ceph RBD CSI plugin. Requires CSIMigration and csiMigrationRBD feature flags enabled and Ceph CSI plugin installed and configured in the cluster. This flag has been deprecated in favor of the InTreePluginRBDUnregister feature flag which prevents the registration of in-tree RBD plugin.
- **CSINodeExpandSecret**: Enable passing secret authentication data to a CSI driver for use during a NodeExpandVolume CSI operation.
- **CSIVolumeHealth**: Enable support for CSI volume health monitoring on node.
- **CustomCPUCFSQuotaPeriod**: Enable nodes to change cpuCFSQuotaPeriod in [kubelet config](#).
- **CustomResourceFieldSelectors**: Enable selectableFields in the [CustomResourceDefinition](#) API to allow filtering of custom resource **list**, **watch** and **deletecollection** requests.
- **CustomResourceValidationExpressions**: Enable expression language validation in CRD which will validate customer resource based on validation rules written in the x-kubernetes-validations extension.
- **DefaultHostNetworkHostPortsInPodTemplates**:

This feature gate controls the point at which a default value for `.spec.containers[*].ports[*].hostPort` is assigned, for Pods using `hostNetwork: true`. The default since Kubernetes v1.28 is to only set a default value in Pods.

Enabling this means a default will be assigned even to the `.spec` of an embedded [PodTemplate](#) (for example, in a Deployment), which is the way that older releases of Kubernetes worked. You should migrate your code so that it does not rely on the legacy behavior.

- **DevicePluginCDIDevices**: Enable support to CDI device IDs in the [Device Plugin](#) API.
- **DisableCloudProviders**: Disables any functionality in kube-apiserver, kube-controller-manager and kubelet related to the `--cloud-provider` component flag.
- **DisableKubeletCloudCredentialProviders**: Disable the in-tree functionality in kubelet to authenticate to a cloud provider container registry for image pull credentials.

- DisableNodeKubeProxyVersion: Disable setting the kubeProxyVersion field of the Node.
- DynamicResourceAllocation: Enables support for resources with custom parameters and a lifecycle that is independent of a Pod.
- EfficientWatchResumption: Allows for storage-originated bookmark (progress notify) events to be delivered to the users. This is only applied to watch operations.
- ElasticIndexedJob: Enables Indexed Jobs to be scaled up or down by mutating both spec.completions and spec.parallelism together such that spec.completions == spec.parallelism. See docs on [elastic Indexed Jobs](#) for more details.
- EventedPLEG: Enable support for the kubelet to receive container life cycle events from the [container runtime](#) via an extension to [CRI](#). (PLEG is an abbreviation for “Pod lifecycle event generator”). For this feature to be useful, you also need to enable support for container lifecycle events in each container runtime running in your cluster. If the container runtime does not announce support for container lifecycle events then the kubelet automatically switches to the legacy generic PLEG mechanism, even if you have this feature gate enabled.
- ExecProbeTimeout: Ensure kubelet respects exec probe timeouts. This feature gate exists in case any of your existing workloads depend on a now-corrected fault where Kubernetes ignored exec probe timeouts. See [readiness probes](#).
- GracefulNodeShutdown: Enables support for graceful shutdown in kubelet. During a system shutdown, kubelet will attempt to detect the shutdown event and gracefully terminate pods running on the node. See [Graceful Node Shutdown](#) for more details.
- GracefulNodeShutdownBasedOnPodPriority: Enables the kubelet to check Pod priorities when shutting down a node gracefully.
- HonorPVReclaimPolicy: Honor persistent volume reclaim policy when it is Delete irrespective of PV-PVC deletion ordering. For more details, check the [PersistentVolume deletion protection finalizer](#) documentation.
- HPAContainerMetrics: Allow [HorizontalPodAutoscalers](#) to scale based on metrics from individual containers within target pods.
- HPAScaleToZero: Enables setting minReplicas to 0 for HorizontalPodAutoscaler resources when using custom or external metrics.
- ImageMaximumGCAge: Enables the kubelet configuration field imageMaximumGCAge, allowing an administrator to specify the age after which an image will be garbage collected.
- InPlacePodVerticalScaling: Enables in-place Pod vertical scaling.
- InTreePluginAWSUnregister: Stops registering the aws-ebs in-tree plugin in kubelet and volume controllers.
- InTreePluginAzureDiskUnregister: Stops registering the azuredisk in-tree plugin in kubelet and volume controllers.
- InTreePluginAzureFileUnregister: Stops registering the azurefile in-tree plugin in kubelet and volume controllers.

- `InTreePluginGCEUnregister`: Stops registering the gce-pd in-tree plugin in kubelet and volume controllers.
- `InTreePluginOpenStackUnregister`: Stops registering the OpenStack cinder in-tree plugin in kubelet and volume controllers.
- `InTreePluginPortworxUnregister`: Stops registering the Portworx in-tree plugin in kubelet and volume controllers.
- `InTreePluginRBDUnregister`: Stops registering the RBD in-tree plugin in kubelet and volume controllers.
- `InTreePluginvSphereUnregister`: Stops registering the vSphere in-tree plugin in kubelet and volume controllers.
- `JobBackoffLimitPerIndex`: Allows specifying the maximal number of pod retries per index in Indexed jobs.
- `JobManagedBy`: Allows to delegate reconciliation of a Job object to an external controller.
- `JobPodFailurePolicy`: Allow users to specify handling of pod failures based on container exit codes and pod conditions.
- `JobPodReplacementPolicy`: Allows you to specify pod replacement for terminating pods in a [Job](#)
- `JobReadyPods`: Enables tracking the number of Pods that have a Ready [condition](#). The count of Ready pods is recorded in the [status](#) of a [Job](#) status.
- `JobSuccessPolicy`: Allow users to specify when a Job can be declared as succeeded based on the set of succeeded pods.
- `KMSv1`: Enables KMS v1 API for encryption at rest. See [Using a KMS Provider for data encryption](#) for more details.
- `KMSv2`: Enables KMS v2 API for encryption at rest. See [Using a KMS Provider for data encryption](#) for more details.
- `KMSv2KDF`: Enables KMS v2 to generate single use data encryption keys. See [Using a KMS Provider for data encryption](#) for more details. If the KMSv2 feature gate is not enabled in your cluster, the value of the KMSv2KDF feature gate has no effect.
- `KubeletCgroupDriverFromCRI`: Enable detection of the kubelet cgroup driver configuration option from the [CRI](#). You can use this feature gate on nodes with a kubelet that supports the feature gate and where there is a CRI container runtime that supports the RuntimeConfig CRI call. If both CRI and kubelet support this feature, the kubelet ignores the cgroupDriver configuration setting (or deprecated `--cgroup-driver` command line argument). If you enable this feature gate and the container runtime doesn't support it, the kubelet falls back to using the driver configured using the cgroupDriver configuration setting. See [Configuring a cgroup driver](#) for more details.
- `KubeletInUserNamespace`: Enables support for running kubelet in a [user namespace](#). See [Running Kubernetes Node Components as a Non-root User](#).

- **KubeletPodResourcesDynamicResources:** Extend the kubelet's pod resources gRPC endpoint to include resources allocated in ResourceClaims via DynamicResourceAllocation API. See [resource allocation reporting](#) for more details. with information about the allocatable resources, enabling clients to properly track the free compute resources on a node.
- **KubeletPodResourcesGet:** Enable the Get gRPC endpoint on kubelet's for Pod resources. This API augments the [resource allocation reporting](#).
- **KubeletSeparateDiskGC:** Enable kubelet to garbage collect container images and containers even when those are on a separate filesystem.
- **KubeletTracing:** Add support for distributed tracing in the kubelet. When enabled, kubelet CRI interface and authenticated http servers are instrumented to generate OpenTelemetry trace spans. See [Traces for Kubernetes System Components](#) for more details.
- **KubeProxyDrainingTerminatingNodes:** Implement connection draining for terminating nodes for externalTrafficPolicy: Cluster services.
- **LegacyServiceAccountTokenCleanUp:** Enable cleaning up Secret-based [service account tokens](#) when they are not used in a specified time (default to be one year).
- **LoadBalancerIPMode:** Allows setting ipMode for Services where type is set to LoadBalancer. See [Specifying IPMode of load balancer status](#) for more information.
- **LocalStorageCapacityIsolationFSQuotaMonitoring:** When LocalStorageCapacityIsolation is enabled for [local ephemeral storage](#) and the backing filesystem for [emptyDir volumes](#) supports project quotas and they are enabled, use project quotas to monitor [emptyDir volume](#) storage consumption rather than filesystem walk for better performance and accuracy.
- **LogarithmicScaleDown:** Enable semi-random selection of pods to evict on controller scaledown based on logarithmic bucketing of pod timestamps.
- **LoggingAlphaOptions:** Allow fine-tuning of experimental, alpha-quality logging options.
- **LoggingBetaOptions:** Allow fine-tuning of experimental, beta-quality logging options.
- **MatchLabelKeysInPodAffinity:** Enable the matchLabelKeys and mismatchLabelKeys field for [pod \(anti\)affinity](#).
- **MatchLabelKeysInPodTopologySpread:** Enable the matchLabelKeys field for [Pod topology spread constraints](#).
- **MaxUnavailableStatefulSet:** Enables setting the maxUnavailable field for the [rolling update strategy](#) of a StatefulSet. The field specifies the maximum number of Pods that can be unavailable during the update.
- **MemoryManager:** Allows setting memory affinity for a container based on NUMA topology.
- **MemoryQoS:** Enable memory protection and usage throttle on pod / container using cgroup v2 memory controller.

- MinDomainsInPodTopologySpread: Enable minDomains in [Pod topology spread constraints](#).
- MultiCIDRServiceAllocator: Track IP address allocations for Service cluster IPs using IPAddress objects.
- NameGenerationRetries: Enables retrying of object creation when the [API server](#) is expected to generate a [name](#). When this feature is enabled, requests using generateName are retried automatically in case the control plane detects a name conflict with an existing object, up to a limit of 8 total attempts.
- NewVolumeManagerReconstruction:
 

Enables improved discovery of mounted volumes during kubelet startup. Since the associated code had been significantly refactored, Kubernetes versions 1.25 to 1.29 allowed you to opt-out in case the kubelet got stuck at the startup, or did not unmount volumes from terminated Pods.

This refactoring was behind the SELinuxMountReadWriteOncePod feature gate in Kubernetes releases 1.25 and 1.26.
- NFTablesProxyMode: Allow running kube-proxy with in [nftables mode](#).
- NodeInclusionPolicyInPodTopologySpread: Enable using nodeAffinityPolicy and nodeTaintsPolicy in [Pod topology spread constraints](#) when calculating pod topology spread skew.
- NodeLogQuery: Enables querying logs of node services using the /logs endpoint.
- NodeOutOfServiceVolumeDetach: When a Node is marked out-of-service using the node.kubernetes.io/out-of-service taint, Pods on the node will be forcefully deleted if they can not tolerate this taint, and the volume detach operations for Pods terminating on the node will happen immediately. The deleted Pods can recover quickly on different nodes.
- NodeSwap: Enable the kubelet to allocate swap memory for Kubernetes workloads on a node. Must be used with KubeletConfiguration.failSwapOn set to false. For more details, please see [swap memory](#)
- OpenAPIEnums: Enables populating "enum" fields of OpenAPI schemas in the spec returned from the API server.
- PDBUnhealthyPodEvictionPolicy: Enables the unhealthyPodEvictionPolicy field of a PodDisruptionBudget. This specifies when unhealthy pods should be considered for eviction. Please see [Unhealthy Pod Eviction Policy](#) for more details.
- PersistentVolumeLastPhaseTransitionTime: Adds a new field to PersistentVolume which holds a timestamp of when the volume last transitioned its phase.
- PodAndContainerStatsFromCRI: Configure the kubelet to gather container and pod stats from the CRI container runtime rather than gathering them from cAdvisor. As of 1.26, this also includes gathering metrics from CRI and emitting them over /metrics/cadvisor (rather than having cAdvisor emit them directly).
- PodDeletionCost: Enable the [Pod Deletion Cost](#) feature which allows users to influence ReplicaSet downscaling order.

- **PodDisruptionConditions:** Enables support for appending a dedicated pod condition indicating that the pod is being deleted due to a disruption.
- **PodHostIPs:** Enable the status.hostIPs field for pods and the [downward API](#). The field lets you expose host IP addresses to workloads.
- **PodIndexLabel:** Enables the Job controller and StatefulSet controller to add the pod index as a label when creating new pods. See [Job completion mode docs](#) and [StatefulSet pod index label docs](#) for more details.
- **PodLifecycleSleepAction:** Enables the sleep action in Container lifecycle hooks.
- **PodReadyToStartContainersCondition:**

Enable the kubelet to mark the [PodReadyToStartContainers](#) condition on pods.

This feature gate was previously known as PodHasNetworkCondition, and the associated condition was named PodHasNetwork.

- **PodSchedulingReadiness:** Enable setting schedulingGates field to control a Pod's [scheduling readiness](#).
- **PortForwardWebsockets:** Allow WebSocket streaming of the portforward sub-protocol (port-forward) from clients requesting version v2 (v2.portforward.k8s.io) of the sub-protocol.
- **ProcMountType:** Enables control over the type proc mounts for containers by setting the procMount field of a SecurityContext.
- **QOSReserved:** Allows resource reservations at the QoS level preventing pods at lower QoS levels from bursting into resources requested at higher QoS levels (memory only for now).
- **ReadWriteOncePod:** Enables the usage of ReadWriteOncePod PersistentVolume access mode.
- **RecoverVolumeExpansionFailure:** Enables users to edit their PVCs to smaller sizes so as they can recover from previously issued volume expansion failures. See [Recovering from Failure when Expanding Volumes](#) for more details.
- **RecursiveReadOnlyMounts:** Enables support for recursive read-only mounts. For more details, see [read-only mounts](#).
- **RelaxedEnvironmentVariableValidation:** Allow almost all printable ASCII characters in environment variables.
- **RemainingItemCount:** Allow the API servers to show a count of remaining items in the response to a [chunking list request](#).
- **RotateKubeletServerCertificate:** Enable the rotation of the server TLS certificate on the kubelet. See [kubelet configuration](#) for more details.
- **RuntimeClassInImageCriApi:** Enables images to be pulled based on the [runtime class](#) of the pods that reference them.

SchedulerQueueingHints: Enables [the scheduler's queueing hints enhancement](#), which

- benefits to reduce the useless requeueing. The scheduler retries scheduling pods if something changes in the cluster that could make the pod scheduled. Queueing hints are internal signals that allow the scheduler to filter the changes in the cluster that are relevant to the unscheduled pod, based on previous scheduling attempts.

- SELinuxMount:

Speeds up container startup by allowing kubelet to mount volumes for a Pod directly with the correct SELinux label instead of changing each file on the volumes recursively. It widens the performance improvements behind the SELinuxMountReadWriteOncePod feature gate by extending the implementation to all volumes.

Enabling the SELinuxMount feature gate requires the feature gate SELinuxMountReadWriteOncePod to be enabled.

- SELinuxMountReadWriteOncePod: Speeds up container startup by allowing kubelet to mount volumes for a Pod directly with the correct SELinux label instead of changing each file on the volumes recursively. The initial implementation focused on ReadWriteOncePod volumes.
- SeparateTaintEvictionController: Enables running TaintEvictionController, that performs [Taint-based Evictions](#), in a controller separated from NodeLifecycleController. When this feature is enabled, users can optionally disable Taint-based Eviction setting the `--controllers=-taint-eviction-controller` flag on the kube-controller-manager.
- ServerSideApply: Enables the [Sever Side Apply \(SSA\)](#) feature on the API Server.
- ServerSideFieldValidation: Enables server-side field validation. This means the validation of resource schema is performed at the API server side rather than the client side (for example, the `kubectl create` or `kubectl apply` command line).
- ServiceAccountTokenJTI: Controls whether JTIs (UUIDs) are embedded into generated service account tokens, and whether these JTIs are recorded into the Kubernetes audit log for future requests made by these tokens.
- ServiceAccountTokenNodeBinding: Controls whether the apiserver allows binding service account tokens to Node objects.
- ServiceAccountTokenNodeBindingValidation: Controls whether the apiserver will validate a Node reference in service account tokens.
- ServiceAccountTokenPodNodeInfo: Controls whether the apiserver embeds the node name and uid for the associated node when issuing service account tokens bound to Pod objects.
- ServiceNodePortStaticSubrange: Enables the use of different port allocation strategies for NodePort Services. For more details, see [reserve NodePort ranges to avoid collisions](#).
- ServiceTrafficDistribution: Allows usage of the optional `spec.trafficDistribution` field in Services. The field offers a way to express preferences for how traffic is distributed to Service endpoints.

- SidecarContainers: Allow setting the restartPolicy of an init container to Always so that
- the container becomes a sidecar container (restartable init containers). See [Sidecar containers and restartPolicy](#) for more details.
  - SizeMemoryBackedVolumes: Enable kubelets to determine the size limit for memory-backed volumes (mainly emptyDir volumes).
  - SkipReadOnlyValidationGCE: Skip validation for GCE, will enable in the next version.
  - StableLoadBalancerNodeSet: Enables less load balancer re-configurations by the service controller (KCCM) as an effect of changing node state.
  - StatefulSetAutoDeletePVC: Allows the use of the optional .spec.persistentVolumeClaimRetentionPolicy field, providing control over the deletion of PVCs in a StatefulSet's lifecycle. See [PersistentVolumeClaim retention](#) for more details.
  - StatefulSetStartOrdinal: Allow configuration of the start ordinal in a StatefulSet. See [Start ordinal](#) for more details.
  - StorageVersionAPI: Enable the [storage version API](#).
  - StorageVersionHash: Allow API servers to expose the storage version hash in the discovery.
  - StorageVersionMigrator: Enables storage version migration. See [Migrate Kubernetes Objects Using Storage Version Migration](#) for more details.
  - StructuredAuthenticationConfiguration: Enable [structured authentication configuration](#) for the API server.
  - StructuredAuthorizationConfiguration: Enable structured authorization configuration, so that cluster administrators can specify more than one [authorization webhook](#) in the API server handler chain.
  - TopologyAwareHints: Enables topology aware routing based on topology hints in EndpointSlices. See [Topology Aware Hints](#) for more details.
  - TopologyManagerPolicyAlphaOptions: Allow fine-tuning of topology manager policies, experimental, Alpha-quality options. This feature gate guards *a group* of topology manager options whose quality level is alpha. This feature gate will never graduate to beta or stable.
  - TopologyManagerPolicyBetaOptions: Allow fine-tuning of topology manager policies, experimental, Beta-quality options. This feature gate guards *a group* of topology manager options whose quality level is beta. This feature gate will never graduate to stable.
  - TopologyManagerPolicyOptions: Enable [fine-tuning](#) of topology manager policies.
  - TranslateStreamCloseWebsocketRequests: Allow WebSocket streaming of the remote command sub-protocol (exec, cp, attach) from clients requesting version 5 (v5) of the sub-protocol.

- **UnauthenticatedHTTP2DOSMitigation**: Enables HTTP/2 Denial of Service (DoS) mitigations for unauthenticated clients. Kubernetes v1.28.0 through v1.28.2 do not include this feature gate.
- **UnknownVersionInteroperabilityProxy**: Proxy resource requests to the correct peer kube-apiserver when multiple kube-apiservers exist at varied versions. See [Mixed version proxy](#) for more information.
- **UserNamespacesPodSecurityStandards**: Enable Pod Security Standards policies relaxation for pods that run with namespaces. You must set the value of this feature gate consistently across all nodes in your cluster, and you must also enable **UserNamespacesSupport** to use this feature.
- **UserNamespacesSupport**: Enable user namespace support for Pods.
- **ValidatingAdmissionPolicy**: Enable [ValidatingAdmissionPolicy](#) support for CEL validations be used in Admission Control.
- **VolumeAttributesClass**: Enable support for VolumeAttributesClasses. See [Volume Attributes Classes](#) for more information.
- **VolumeCapacityPriority**: Enable support for prioritizing nodes in different topologies based on available PV capacity.
- **WatchBookmark**: Enable support for watch bookmark events.
- **WatchList**: Enable support for [streaming initial state of objects in watch requests](#).
- **WindowsHostNetwork**: Enables support for joining Windows containers to a hosts' network namespace.
- **WinDSR**: Allows kube-proxy to create DSR loadbalancers for Windows.
- **WinOverlay**: Allows kube-proxy to run in overlay mode for Windows.
- **ZeroLimitedNominalConcurrencyShares**: Allow [Priority & Fairness](#) in the API server to use a zero value for the `nominalConcurrencyShares` field of the `limited` section of a priority level.

## What's next

- The [deprecation policy](#) for Kubernetes explains the project's approach to removing features and components.
- Since Kubernetes 1.24, new beta APIs are not enabled by default. When enabling a beta feature, you will also need to enable any associated API resources. For example, to enable a particular resource like `storage.k8s.io/v1beta1/csistoragecapacities`, set `--runtime-config=storage.k8s.io/v1beta1/csistoragecapacities`. See [API Versioning](#) for more details on the command line flags.

# Feature Gates (removed)

This page contains list of feature gates that have been removed. The information on this page is for reference. A removed feature gate is different from a GA'ed or deprecated one in that a removed one is no longer recognized as a valid feature gate. However, a GA'ed or a deprecated feature gate is still recognized by the corresponding Kubernetes components although they are unable to cause any behavior differences in a cluster.

For feature gates that are still recognized by the Kubernetes components, please refer to the [Alpha/Beta feature gate table](#) or the [Graduated/Deprecated feature gate table](#)

## Feature gates that are removed

In the following table:

- The "From" column contains the Kubernetes release when a feature is introduced or its release stage is changed.
- The "To" column, if not empty, contains the last Kubernetes release in which you can still use a feature gate. If the feature stage is either "Deprecated" or "GA", the "To" column is the Kubernetes release when the feature is removed.

Feature Gates Removed

| Feature                        | Default | Stage      | From | To   |
|--------------------------------|---------|------------|------|------|
| Accelerators                   | false   | Alpha      | 1.6  | 1.10 |
| Accelerators                   | –       | Deprecated | 1.11 | 1.11 |
| AdvancedAuditing               | false   | Alpha      | 1.7  | 1.7  |
| AdvancedAuditing               | true    | Beta       | 1.8  | 1.11 |
| AdvancedAuditing               | true    | GA         | 1.12 | 1.27 |
| AffinityInAnnotations          | false   | Alpha      | 1.6  | 1.7  |
| AffinityInAnnotations          | –       | Deprecated | 1.8  | 1.8  |
| AllowExtTrafficLocalEndpoints  | false   | Beta       | 1.4  | 1.6  |
| AllowExtTrafficLocalEndpoints  | true    | GA         | 1.7  | 1.9  |
| AllowInsecureBackendProxy      | true    | Beta       | 1.17 | 1.20 |
| AllowInsecureBackendProxy      | true    | GA         | 1.21 | 1.25 |
| APISelfSubjectReview           | false   | Alpha      | 1.26 | 1.26 |
| APISelfSubjectReview           | true    | Beta       | 1.27 | 1.27 |
| APISelfSubjectReview           | true    | GA         | 1.28 | 1.29 |
| AttachVolumeLimit              | false   | Alpha      | 1.11 | 1.11 |
| AttachVolumeLimit              | true    | Beta       | 1.12 | 1.16 |
| AttachVolumeLimit              | true    | GA         | 1.17 | 1.21 |
| BalanceAttachedNodeVolumes     | false   | Alpha      | 1.11 | 1.21 |
| BalanceAttachedNodeVolumes     | false   | Deprecated | 1.22 | 1.22 |
| BlockVolume                    | false   | Alpha      | 1.9  | 1.12 |
| BlockVolume                    | true    | Beta       | 1.13 | 1.17 |
| BlockVolume                    | true    | GA         | 1.18 | 1.21 |
| BoundServiceAccountTokenVolume | false   | Alpha      | 1.13 | 1.20 |
| BoundServiceAccountTokenVolume | true    | Beta       | 1.21 | 1.21 |

| Feature                          | Default | Stage      | From | To   |
|----------------------------------|---------|------------|------|------|
| BoundServiceAccountTokenVolume   | true    | GA         | 1.22 | 1.23 |
| ConfigurableFSGroupPolicy        | false   | Alpha      | 1.18 | 1.19 |
| ConfigurableFSGroupPolicy        | true    | Beta       | 1.20 | 1.22 |
| ConfigurableFSGroupPolicy        | true    | GA         | 1.23 | 1.25 |
| ControllerManagerLeaderMigration | false   | Alpha      | 1.21 | 1.21 |
| ControllerManagerLeaderMigration | true    | Beta       | 1.22 | 1.23 |
| ControllerManagerLeaderMigration | true    | GA         | 1.24 | 1.26 |
| CRIOContainerLogRotation         | false   | Alpha      | 1.10 | 1.10 |
| CRIOContainerLogRotation         | true    | Beta       | 1.11 | 1.20 |
| CRIOContainerLogRotation         | true    | GA         | 1.21 | 1.22 |
| CronJobControllerV2              | false   | Alpha      | 1.20 | 1.20 |
| CronJobControllerV2              | true    | Beta       | 1.21 | 1.21 |
| CronJobControllerV2              | true    | GA         | 1.22 | 1.23 |
| CronJobTimeZone                  | false   | Alpha      | 1.24 | 1.24 |
| CronJobTimeZone                  | true    | Beta       | 1.25 | 1.26 |
| CronJobTimeZone                  | true    | GA         | 1.27 | 1.28 |
| CSIBlockVolume                   | false   | Alpha      | 1.11 | 1.13 |
| CSIBlockVolume                   | true    | Beta       | 1.14 | 1.17 |
| CSIBlockVolume                   | true    | GA         | 1.18 | 1.21 |
| CSIDriverRegistry                | false   | Alpha      | 1.12 | 1.13 |
| CSIDriverRegistry                | true    | Beta       | 1.14 | 1.17 |
| CSIDriverRegistry                | true    | GA         | 1.18 | 1.21 |
| CSIInlineVolume                  | false   | Alpha      | 1.15 | 1.15 |
| CSIInlineVolume                  | true    | Beta       | 1.16 | 1.24 |
| CSIInlineVolume                  | true    | GA         | 1.25 | 1.26 |

## Descriptions for removed feature gates

- **Accelerators**: Provided an early form of plugin to enable Nvidia GPU support when using Docker Engine; no longer available. See [Device Plugins](#) for an alternative.
- **AdvancedAuditing**: Enable [advanced auditing](#)
- **AffinityInAnnotations**: Enable setting [Pod affinity or anti-affinity](#).
- **AllowExtTrafficLocalEndpoints**: Enable a service to route external requests to node local endpoints.
- **AllowInsecureBackendProxy**: Enable the users to skip TLS verification of kubelets on Pod log requests.
- **APISelfSubjectReview**: Activate the SelfSubjectReview API which allows users to see the requesting subject's authentication information. See [API access to authentication information for a client](#) for more details.
- **AttachVolumeLimit**: Enable volume plugins to report limits on number of volumes that can be attached to a node. See [dynamic volume limits](#) for more details.
- **BalanceAttachedNodeVolumes**: Include volume count on node to be considered for balanced resource allocation while scheduling. A node which has closer CPU, memory utilization, and volume count is favored by the scheduler while making decisions.
- **BlockVolume**: Enable the definition and consumption of raw block devices in Pods. See [Raw Block Volume Support](#) for more details.
- **BoundServiceAccountTokenVolume**:

Migrate ServiceAccount volumes to use a projected volume consisting of a ServiceAccountTokenVolumeProjection. Cluster admins can use metric `serviceaccount_stale_tokens_total` to monitor workloads that are depending on the extended tokens. If there are no such workloads, turn off extended tokens by starting kube-apiserver with flag `--service-account-extend-token-expiration=false`.

Check [Bound Service Account Tokens](#) for more details.

- **ConfigurableFSGroupPolicy**: Allows user to configure volume permission change policy for fsGroups when mounting a volume in a Pod. See [Configure volume permission and ownership change policy for Pods](#) for more details.
- **ControllerManagerLeaderMigration**: Enables Leader Migration for [kube-controller-manager](#) and [cloud-controller-manager](#) which allows a cluster operator to live migrate controllers from the kube-controller-manager into an external controller-manager (e.g. the cloud-controller-manager) in an HA cluster without downtime.

- CRIContainerLogRotation: Enable container log rotation for CRI container runtime. The default max size of a log file is 10MB and the default max number of log files allowed for a container is 5. These values can be configured in the kubelet config. See [logging at node level](#) for more details.
- CronJobControllerV2: Use an alternative implementation of the [CronJob](#) controller. Otherwise, version 1 of the same controller is selected.
  - CronJobTimeZone: Allow the use of the timeZone optional field in [CronJobs](#)
  - CSIBlockVolume: Enable external CSI volume drivers to support block storage. See [csi raw block volume support](#) for more details.
  - CSIDriverRegistry: Enable all logic related to the CSIDriver API object in csi.storage.k8s.io.
  - CSIInlineVolume: Enable CSI Inline volumes support for pods.
  - CSIMigration: Enables shims and translation logic to route volume operations from in-tree plugins to corresponding pre-installed CSI plugins
  - CSIMigrationAWS: Enables shims and translation logic to route volume operations from the AWS-EBS in-tree plugin to EBS CSI plugin. Supports falling back to in-tree EBS plugin for mount operations to nodes that have the feature disabled or that do not have EBS CSI plugin installed and configured. Does not support falling back for provision operations, for those the CSI plugin must be installed and configured.
  - CSIMigrationAWSComplete: Stops registering the EBS in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the AWS-EBS in-tree plugin to EBS CSI plugin. Requires CSIMigration and CSIMigrationAWS feature flags enabled and EBS CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the InTreePluginAWSUnregister feature flag which prevents the registration of in-tree EBS plugin.
  - CSIMigrationAzureDisk: Enables shims and translation logic to route volume operations from the Azure-Disk in-tree plugin to AzureDisk CSI plugin. Supports falling back to in-tree AzureDisk plugin for mount operations to nodes that have the feature disabled or that do not have AzureDisk CSI plugin installed and configured. Does not support falling back for provision operations, for those the CSI plugin must be installed and configured. Requires CSIMigration feature flag enabled.
  - CSIMigrationAzureDiskComplete: Stops registering the Azure-Disk in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the Azure-Disk in-tree plugin to AzureDisk CSI plugin. Requires CSIMigration and CSIMigrationAzureDisk feature flags enabled and AzureDisk CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the InTreePluginAzureDiskUnregister feature flag which prevents the registration of in-tree AzureDisk plugin.
  - CSIMigrationAzureFile: Enables shims and translation logic to route volume operations from the Azure-File in-tree plugin to AzureFile CSI plugin. Supports falling back to in-tree AzureFile plugin for mount operations to nodes that have the feature disabled or that do not have AzureFile CSI plugin installed and configured. Does not support falling back

for provision operations, for those the CSI plugin must be installed and configured. Requires CSIMigration feature flag enabled.

- **CSIMigrationAzureFileComplete**: Stops registering the Azure-File in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the Azure-File in-tree plugin to AzureFile CSI plugin. Requires CSIMigration and CSIMigrationAzureFile feature flags enabled and AzureFile CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the InTreePluginAzureFileUnregister feature flag which prevents the registration of in-tree AzureFile plugin.
- **CSIMigrationGCE**: Enables shims and translation logic to route volume operations from the GCE-PD in-tree plugin to PD CSI plugin. Supports falling back to in-tree GCE plugin for mount operations to nodes that have the feature disabled or that do not have PD CSI plugin installed and configured. Does not support falling back for provision operations, for those the CSI plugin must be installed and configured. Requires CSIMigration feature flag enabled.
- **CSIMigrationGCEComplete**: Stops registering the GCE-PD in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the GCE-PD in-tree plugin to PD CSI plugin. Requires CSIMigration and CSIMigrationGCE feature flags enabled and PD CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the InTreePluginGCEUnregister feature flag which prevents the registration of in-tree GCE PD plugin.
- **CSIMigrationOpenStack**: Enables shims and translation logic to route volume operations from the Cinder in-tree plugin to Cinder CSI plugin. Supports falling back to in-tree Cinder plugin for mount operations to nodes that have the feature disabled or that do not have Cinder CSI plugin installed and configured. Does not support falling back for provision operations, for those the CSI plugin must be installed and configured. Requires CSIMigration feature flag enabled.
- **CSIMigrationOpenStackComplete**: Stops registering the Cinder in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the Cinder in-tree plugin to Cinder CSI plugin. Requires CSIMigration and CSIMigrationOpenStack feature flags enabled and Cinder CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the InTreePluginOpenStackUnregister feature flag which prevents the registration of in-tree openstack cinder plugin.
- **CSIMigrationvSphere**: Enables shims and translation logic to route volume operations from the vSphere in-tree plugin to vSphere CSI plugin. Supports falling back to in-tree vSphere plugin for mount operations to nodes that have the feature disabled or that do not have vSphere CSI plugin installed and configured. Does not support falling back for provision operations, for those the CSI plugin must be installed and configured. Requires CSIMigration feature flag enabled.
- **CSIMigrationvSphereComplete**: Stops registering the vSphere in-tree plugin in kubelet and volume controllers and enables shims and translation logic to route volume operations from the vSphere in-tree plugin to vSphere CSI plugin. Requires CSIMigration and CSIMigrationvSphere feature flags enabled and vSphere CSI plugin installed and configured on all nodes in the cluster. This flag has been deprecated in favor of the

InTreePluginvSphereUnregister feature flag which prevents the registration of in-tree vsphere plugin.

- CSINodeInfo: Enable all logic related to the CSINodeInfo API object in `csi.storage.k8s.io`.
- CSIPersistentVolume: Enable discovering and mounting volumes provisioned through a [CSI \(Container Storage Interface\)](#) compatible volume plugin.
- CSIServiceAccountToken: Enable CSI drivers to receive the pods' service account token that they mount volumes for. See [Token Requests](#).
- CSIStorageCapacity: Enables CSI drivers to publish storage capacity information and the Kubernetes scheduler to use that information when scheduling pods. See [Storage Capacity](#). Check the [csi volume type](#) documentation for more details.
- CSIVolumeFSGroupPolicy: Allows CSIDrivers to use the fsGroupPolicy field. This field controls whether volumes created by a CSIDriver support volume ownership and permission modifications when these volumes are mounted.
- CSRDuration: Allows clients to request a duration for certificates issued via the Kubernetes CSR API.
- CustomPodDNS: Enable customizing the DNS settings for a Pod using its `dnsConfig` property. Check [Pod's DNS Config](#) for more details.
- CustomResourceDefaulting: Enable CRD support for default values in OpenAPI v3 validation schemas.
- CustomResourcePublishOpenAPI: Enables publishing of CRD OpenAPI specs.
- CustomResourceSubresources: Enable `/status` and `/scale` subresources on resources created from [CustomResourceDefinition](#).
- CustomResourceValidation: Enable schema based validation on resources created from [CustomResourceDefinition](#).
- CustomResourceWebhookConversion: Enable webhook-based conversion on resources created from [CustomResourceDefinition](#).
- DaemonSetUpdateSurge: Enables the DaemonSet workloads to maintain availability during update per node. See [Perform a Rolling Update on a DaemonSet](#).
- DefaultPodTopologySpread: Enables the use of PodTopologySpread scheduling plugin to do [default spreading](#).
- DelegateFSGroupToCSIDriver: If supported by the CSI driver, delegates the role of applying fsGroup from a Pod's securityContext to the driver by passing fsGroup through the NodeStageVolume and NodePublishVolume CSI calls.
- DevicePlugins: Enable the [device-plugins](#) based resource provisioning on nodes.
- DisableAcceleratorUsageMetrics: [Disable accelerator metrics collected by the kubelet](#).
- DownwardAPIHugePages: Enables usage of hugepages in [downward API](#).

- DryRun: Enable server-side [dry run](#) requests so that validation, merging, and mutation can be tested without committing.
- DynamicAuditing: Used to enable dynamic auditing before v1.19.
- DynamicKubeletConfig: Enable the dynamic configuration of kubelet. The feature is no longer supported outside of supported skew policy. The feature gate was removed from kubelet in 1.24.
- DynamicProvisioningScheduling: Extend the default scheduler to be aware of volume topology and handle PV provisioning. This feature was superseded by the VolumeScheduling feature in v1.12.
- DynamicVolumeProvisioning: Enable the [dynamic provisioning](#) of persistent volumes to Pods.
- EnableAggregatedDiscoveryTimeout: Enable the five second timeout on aggregated discovery calls.
- EnableEquivalenceClassCache: Enable the scheduler to cache equivalence of nodes when scheduling Pods.
- EndpointSlice: Enables EndpointSlices for more scalable and extensible network endpoints. See [Enabling EndpointSlices](#).
- EndpointSliceNodeName: Enables EndpointSlice nodeName field.
- EndpointSliceProxying: When enabled, kube-proxy running on Linux will use EndpointSlices as the primary data source instead of Endpoints, enabling scalability and performance improvements. See [Enabling Endpoint Slices](#).
- EndpointSliceTerminatingCondition: Enables EndpointSlice terminating and serving condition fields.
- EphemeralContainers: Enable the ability to add [ephemeral containers](#) to running Pods.
- EvenPodsSpread: Enable pods to be scheduled evenly across topology domains. See [Pod Topology Spread Constraints](#).
- ExpandCSIVolumes: Enable the expanding of CSI volumes.
- ExpandedDNSConfig: Enable kubelet and kube-apiserver to allow more DNS search paths and longer list of DNS search paths. This feature requires container runtime support(Containerd: v1.5.6 or higher, CRI-O: v1.22 or higher). See [Expanded DNS Configuration](#).
- ExpandInUsePersistentVolumes: Enable expanding in-use PVCs. See [Resizing an in-use PersistentVolumeClaim](#).
- ExpandPersistentVolumes: Enable the expanding of persistent volumes. See [Expanding Persistent Volumes Claims](#).
- ExperimentalCriticalPodAnnotation: Enable annotating specific pods as *critical* so that their [scheduling is guaranteed](#). This feature is deprecated by Pod Priority and Preemption as of v1.13.

- **ExperimentalHostUserNamespaceDefaulting**: Enabling the defaulting user namespace to host. This is for containers that are using other host namespaces, host mounts, or containers that are privileged or using specific non-namespaced capabilities (e.g. MKNODE, SYS\_MODULE etc.). This should only be enabled if user namespace remapping is enabled in the Docker daemon.
- **ExternalPolicyForExternalIP**: Fix a bug where ExternalTrafficPolicy is not applied to Service ExternalIPs.
- **GCERegionalPersistentDisk**: Enable the regional PD feature on GCE.
- **GenericEphemeralVolume**: Enables ephemeral, inline volumes that support all features of normal volumes (can be provided by third-party storage vendors, storage capacity tracking, restore from snapshot, etc.). See [Ephemeral Volumes](#).
- **GRPCContainerProbe**: Enables the gRPC probe method for {Liveness,Readiness,Startup} Probe. See [Configure Liveness, Readiness and Startup Probes](#).
- **HugePages**: Enable the allocation and consumption of pre-allocated [huge pages](#).
- **HugePageStorageMediumSize**: Enable support for multiple sizes pre-allocated [huge pages](#).
- **HyperVContainer**: Enable [Hyper-V isolation](#) for Windows containers.
- **IdentifyPodOS**: Allows the Pod OS field to be specified. This helps in identifying the OS of the pod authoritatively during the API server admission time.
- **ImmutableEphemeralVolumes**: Allows for marking individual Secrets and ConfigMaps as immutable for better safety and performance.
- **IndexedJob**: Allows the [Job](#) controller to manage Pod completions per completion index.
- **IngressClassNamespacedParams**: Allow namespace-scoped parameters reference in IngressClass resource. This feature adds two fields - Scope and Namespace to IngressClass.spec.parameters.
- **Initializers**: Allow asynchronous coordination of object creation using the Initializers admission plugin.
- **IPTablesOwnershipCleanup**: This causes kubelet to no longer create legacy iptables rules.
- **IPv6DualStack**: Enable [dual stack](#) support for IPv6.
- **JobMutableNodeSchedulingDirectives**: Allows updating node scheduling directives in the pod template of [Job](#).
- **JobTrackingWithFinalizers**: Enables tracking [Job](#) completions without relying on Pods remaining in the cluster indefinitely. The Job controller uses Pod finalizers and a field in the Job status to keep track of the finished Pods to count towards completion.
- **KubeletConfigFile**: Enable loading kubelet configuration from a file specified using a config file. See [setting kubelet parameters via a config file](#) for more details.

- **KubeletCredentialProviders:** Enable kubelet exec credential providers for image pull credentials.
- **KubeletPluginsWatcher:** Enable probe-based plugin watcher utility to enable kubelet to discover plugins such as [CSI volume drivers](#).
- **KubeletPodResources:** Enable the kubelet's pod resources gRPC endpoint. See [Support Device Monitoring](#) for more details.
- **KubeletPodResourcesGetAllocatable:** Enable the kubelet's pod resources GetAllocatableResources functionality. This API augments the [resource allocation reporting](#)
- **LegacyNodeRoleBehavior:** When disabled, legacy behavior in service load balancers and node disruption will ignore the node-role.kubernetes.io/master label in favor of the feature-specific labels provided by NodeDisruptionExclusion and ServiceNodeExclusion.
- **LegacyServiceAccountTokenNoAutoGeneration:** Stop auto-generation of Secret-based [service account tokens](#).
- **LegacyServiceAccountTokenTracking:** Track usage of Secret-based [service account tokens](#).
- **LocalStorageCapacityIsolation:** Enable the consumption of [local ephemeral storage](#) and also the sizeLimit property of an [emptyDir volume](#).
- **MinimizeIPTablesRestore:** Enables new performance improvement logics in the kube-proxy iptables mode.
- **MixedProtocolLBService:** Enable using different protocols in the same LoadBalancer type Service instance.
- **MountContainers:** Enable using utility containers on host as the volume mounter.
- **MountPropagation:** Enable sharing volume mounted by one container to other containers or pods. For more details, please see [mount propagation](#).
- **MultiCIDRRangeAllocator:** Enables the MultiCIDR range allocator.
- **NamespaceDefaultLabelName:** Configure the API Server to set an immutable [label](#) kubernetes.io/metadata.name on all namespaces, containing the namespace name.
- **NetworkPolicyEndPort:** Allows you to define ports in a [NetworkPolicy](#) rule as a range of port numbers.
- **NetworkPolicyStatus:** Enable the status subresource for NetworkPolicy objects.
- **NodeDisruptionExclusion:** Enable use of the Node label node.kubernetes.io/exclude-disruption which prevents nodes from being evacuated during zone failures.
- **NodeLease:** Enable the new Lease API to report node heartbeats, which could be used as a node health signal.
- **NonPreemptingPriority:** Enable preemptionPolicy field for PriorityClass and Pod.

- OpenAPIV3: Enables the API server to publish OpenAPI v3.
- PersistentLocalVolumes: Enable the usage of local volume type in Pods. Pod affinity has to be specified if requesting a local volume.
- PodAffinityNamespaceSelector: Enable the [Pod Affinity Namespace Selector](#) and [CrossNamespacePodAffinity](#) quota scope features.
- PodDisruptionBudget: Enable the [PodDisruptionBudget](#) feature.
- PodHasNetworkCondition: Enable the kubelet to mark the [PodHasNetwork](#) condition on pods. This was renamed to PodReadyToStartContainersCondition in 1.28.
- PodOverhead: Enable the [PodOverhead](#) feature to account for pod overheads.
- PodPriority: Enable the descheduling and preemption of Pods based on their [priorities](#).
- PodReadinessGates: Enable the setting of PodReadinessGate field for extending Pod readiness evaluation. See [Pod readiness gate](#) for more details.
- PodSecurity: Enables the PodSecurity admission plugin.
- PodShareProcessNamespace: Enable the setting of shareProcessNamespace in a Pod for sharing a single process namespace between containers running in a pod. More details can be found in [Share Process Namespace between Containers in a Pod](#).
- PreferNominatedNode: This flag tells the scheduler whether the nominated nodes will be checked first before looping through all the other nodes in the cluster.
- ProbeTerminationGracePeriod: Enable [setting probe-level terminationGracePeriodSeconds](#) on pods. See the [enhancement proposal](#) for more details.
- ProxyTerminatingEndpoints: Enable the kube-proxy to handle terminating endpoints when ExternalTrafficPolicy=Local.
- PVCProtection: Enable the prevention of a PersistentVolumeClaim (PVC) from being deleted when it is still used by any Pod.
- ReadOnlyAPIDataVolumes:
 

Set [configMap](#), [secret](#), [downwardAPI](#) and [projected volumes](#) to be mounted read-only.

Since Kubernetes v1.10, these volume types are always read-only and you cannot opt out.
- RemoveSelfLink: Sets the .metadata.selfLink field to blank (empty string) for all objects and collections. This field has been deprecated since the Kubernetes v1.16 release. When this feature is enabled, the .metadata.selfLink field remains part of the Kubernetes API, but is always unset.
- RequestManagement: Enables managing request concurrency with prioritization and fairness at each API server. Deprecated by APIPriorityAndFairness since 1.17.
- ResourceLimitsPriorityFunction: Enable a scheduler priority function that assigns a lowest possible score of 1 to a node that satisfies at least one of the input Pod's cpu and memory limits. The intent is to break ties between nodes with same scores.

ResourceQuotaScopeSelectors: Enable resource quota scope selectors.

- 
- RetroactiveDefaultStorageClass: Allow assigning StorageClass to unbound PVCs retroactively.
- RootCAConfigMap: Configure the kube-controller-manager to publish a [ConfigMap](#) named kube-root-ca.crt to every namespace. This ConfigMap contains a CA bundle used for verifying connections to the kube-apiserver. See [Bound Service Account Tokens](#) for more details.
- RotateKubeletClientCertificate: Enable the rotation of the client TLS certificate on the kubelet. See [kubelet configuration](#) for more details.
- RunAsGroup: Enable control over the primary group ID set on the init processes of containers.
- RuntimeClass: Enable the [RuntimeClass](#) feature for selecting container runtime configurations.
- ScheduleDaemonSetPods: Enable DaemonSet Pods to be scheduled by the default scheduler instead of the DaemonSet controller.
- SCTPSupport: Enables the *SCTP* protocol value in Pod, Service, Endpoints, EndpointSlice, and NetworkPolicy definitions.
- SeccompDefault: Enables the use of RuntimeDefault as the default seccomp profile for all workloads. The seccomp profile is specified in the securityContext of a Pod and/or a Container.
- SecurityContextDeny: This gate signals that the SecurityContextDeny admission controller is deprecated.
- SelectorIndex: Allows label and field based indexes in API server watch cache to accelerate list operations.
- ServiceAccountIssuerDiscovery: Enable OIDC discovery endpoints (issuer and JWKS URLs) for the service account issuer in the API server. See [Configure Service Accounts for Pods](#) for more details.
- ServiceAppProtocol: Enables the appProtocol field on Services and Endpoints.
- ServiceInternalTrafficPolicy: Enables the internalTrafficPolicy field on Services
- ServiceIPStaticSubrange: Enables a strategy for Services ClusterIP allocations, whereby the ClusterIP range is subdivided. Dynamic allocated ClusterIP addresses will be allocated preferentially from the upper range allowing users to assign static ClusterIPs from the lower range with a low risk of collision. See [Avoiding collisions](#) for more details.
- ServiceLBNodePortControl: Enables the allocateLoadBalancerNodePorts field on Services.
- ServiceLoadBalancerClass: Enables the loadBalancerClass field on Services. See [Specifying class of load balancer implementation](#) for more details.
- ServiceLoadBalancerFinalizer: Enable finalizer protection for Service load balancers.

- **ServiceNodeExclusion:** Enable the exclusion of nodes from load balancers created by a cloud provider. A node is eligible for exclusion if labelled with "node.kubernetes.io/exclude-from-external-load-balancers".
- **ServiceTopology:** Enable service to route traffic based upon the Node topology of the cluster.
- **SetHostnameAsFQDN:** Enable the ability of setting Fully Qualified Domain Name(FQDN) as the hostname of a pod. See [Pod's setHostnameAsFQDN field](#).
- **StartupProbe:** Enable the [startup](#) probe in the kubelet.
- **StatefulSetMinReadySeconds:** Allows minReadySeconds to be respected by the StatefulSet controller.
- **StorageObjectInUseProtection:** Postpone the deletion of PersistentVolume or PersistentVolumeClaim objects if they are still being used.
- **StreamingProxyRedirects:** Instructs the API server to intercept (and follow) redirects from the backend (kubelet) for streaming requests. Examples of streaming requests include the exec, attach and port-forward requests.
- **SupportIPVSProxyMode:** Enable providing in-cluster service load balancing using IPVS. See [service proxies](#) for more details.
- **SupportNodePidsLimit:** Enable the support to limiting PIDs on the Node. The parameter pid=<number> in the --system-reserved and --kube-reserved options can be specified to ensure that the specified number of process IDs will be reserved for the system as a whole and for Kubernetes system daemons respectively.
- **SupportPodPidsLimit:** Enable the support to limiting PIDs in Pods.
- **SuspendJob:** Enable support to suspend and resume Jobs. For more details, see [the Jobs docs](#).
- **Sysctls:** Enable support for namespaced kernel parameters (sysctls) that can be set for each pod. See [sysctls](#) for more details.
- **TaintBasedEvictions:** Enable evicting pods from nodes based on taints on Nodes and tolerations on Pods. See [taints and tolerations](#) for more details.
- **TaintNodesByCondition:** Enable automatic tainting nodes based on [node conditions](#).
- **TokenRequest:** Enable the TokenRequest endpoint on service account resources.
- **TokenRequestProjection:** Enable the injection of service account tokens into a Pod through a [projected volume](#).
- **TopologyManager:** Enable a mechanism to coordinate fine-grained hardware resource assignments for different components in Kubernetes. See [Control Topology Management Policies on a node](#).
- **TTLAfterFinished:** Allow a [TTL controller](#) to clean up resources after they finish execution.

- `UserNamespacesStatelessPodsSupport`: Enable user namespace support for stateless Pods. This feature gate was superseded by the `UserNamespacesSupport` feature gate in the Kubernetes v1.28 release.
- `ValidateProxyRedirects`: This flag controls whether the API server should validate that redirects are only followed to the same host. Only used if the `StreamingProxyRedirects` flag is enabled.
- `VolumePVCDDataSource`: Enable support for specifying an existing PVC as a `DataSource`.
- `VolumeScheduling`: Enable volume topology aware scheduling and make the `PersistentVolumeClaim` (PVC) binding aware of scheduling decisions. It also enables the usage of [local](#) volume type when used together with the `PersistentLocalVolumes` feature gate.
- `VolumeSnapshotDataSource`: Enable volume snapshot data source support.
- `VolumeSubpath`: Allow mounting a subpath of a volume in a container.
- `VolumeSubpathEnvExpansion`: Enable `subPathExpr` field for expanding environment variables into a `subPath`.
- `WarningHeaders`: Allow sending warning headers in API responses.
- `WindowsEndpointSliceProxying`: When enabled, kube-proxy running on Windows will use `EndpointSlices` as the primary data source instead of `Endpoints`, enabling scalability and performance improvements. See [Enabling Endpoint Slices](#).
- `WindowsGMSA`: Enables passing of GMSA credential specs from pods to container runtimes.
- `WindowsHostProcessContainers`: Enables support for Windows `HostProcess` containers.
- `WindowsRunAsUserName`: Enable support for running applications in Windows containers with as a non-default user. See [Configuring RunAsUserName](#) for more details.

# kubelet

## Synopsis

The kubelet is the primary "node agent" that runs on each node. It can register the node with the apiserver using one of: the hostname; a flag to override the hostname; or specific logic for a cloud provider.

The kubelet works in terms of a `PodSpec`. A `PodSpec` is a YAML or JSON object that describes a pod. The kubelet takes a set of `PodSpecs` that are provided through various mechanisms (primarily through the apiserver) and ensures that the containers described in those `PodSpecs` are running and healthy. The kubelet doesn't manage containers which were not created by Kubernetes.

Other than from a PodSpec from the apiserver, there are two ways that a container manifest can be provided to the kubelet.

- File: Path passed as a flag on the command line. Files under this path will be monitored periodically for updates. The monitoring period is 20s by default and is configurable via a flag.
- HTTP endpoint: HTTP endpoint passed as a parameter on the command line. This endpoint is checked every 20 seconds (also configurable with a flag).

kubelet [flags]

## Options

|                                                                                                                                                                      |                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| --address string                                                                                                                                                     | Default: 0.0.0.0              |
| The IP address for the kubelet to serve on (set to 0.0.0.0 or :: for listening on all interfaces and IP address family)                                              |                               |
| --allowed-unsafe-sysctls strings                                                                                                                                     |                               |
| Comma-separated whitelist of unsafe sysctls or unsafe sysctl patterns (ending in *). Use these at your own risk                                                      |                               |
| --anonymous-auth                                                                                                                                                     | Default: true                 |
| Enables anonymous requests to the kubelet server. Requests that are not rejected by another authentication method are accepted                                       |                               |
| --authentication-token-webhook                                                                                                                                       |                               |
| Use the TokenReview API to determine authentication for bearer tokens. (DEPRECATED: This parameter should be removed in the future)                                  |                               |
| --authentication-token-webhook-cache-ttl duration                                                                                                                    | Default: 2m0s                 |
| The duration to cache responses from the webhook token authenticator. (DEPRECATED: This parameter should be removed in the future)                                   |                               |
| --authorization-mode string                                                                                                                                          | Default: AlwaysAllow          |
| Authorization mode for kubelet server. Valid options are "AlwaysAllow" or "Webhook". Webhook mode uses the TokenReview API                                           |                               |
| --authorization-webhook-cache-authorized-ttl duration                                                                                                                | Default: 5m0s                 |
| The duration to cache 'authorized' responses from the webhook authorizer. (DEPRECATED: This parameter should be removed in the future)                               |                               |
| --authorization-webhook-cache-unauthorized-ttl duration                                                                                                              | Default: 30s                  |
| The duration to cache 'unauthorized' responses from the webhook authorizer. (DEPRECATED: This parameter should be removed in the future)                             |                               |
| --bootstrap-kubeconfig string                                                                                                                                        |                               |
| Path to a kubeconfig file that will be used to get client certificate for kubelet. If the file specified by --kubeconfig is not found, kubelet will use this file    |                               |
| --cert-dir string                                                                                                                                                    | Default: /var/lib/kubelet/pki |
| The directory where the TLS certs are located. If --tls-cert-file and --tls-private-key-file are provided, this flag is ignored                                      |                               |
| --cgroup-driver string                                                                                                                                               | Default: cgroupfs             |
| Driver that the kubelet uses to manipulate cgroups on the host. Possible values: "cgroupfs", "systemd". (DEPRECATED: This parameter should be removed in the future) |                               |
| --cgroup-root string                                                                                                                                                 | Default: "                    |
| Optional root cgroup to use for pods. This is handled by the container runtime on a best effort basis. Default is empty string                                       |                               |
| --cgroups-per-qos                                                                                                                                                    | Default: true                 |
| Enable creation of QoS cgroup hierarchy, if true, top level QoS and pod cgroups are created. (DEPRECATED: This parameter should be removed in the future)            |                               |
| --client-ca-file string                                                                                                                                              |                               |
| If set, any request presenting a client certificate signed by one of the authorities in the client-ca-file is authorized to get a bearer token                       |                               |
| --cloud-config string                                                                                                                                                |                               |
| The path to the cloud provider configuration file. Empty string for no configuration file. (DEPRECATED: This parameter should be removed in the future)              |                               |
| --cloud-provider string                                                                                                                                              |                               |
| The provider for cloud services. Set to empty string for running with no cloud provider. Set to 'external' for non-cloud providers                                   |                               |
| --cluster-dns strings                                                                                                                                                |                               |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| Comma-separated list of DNS server IP address. This value is used for containers DNS server in case of Pods        |
| <b>Note:</b> all DNS servers appearing in the list MUST serve the same set of records otherwise name resolution w  |
| --cluster-domain string                                                                                            |
| Domain for this cluster. If set, kubelet will configure all containers to search this domain in addition to the h  |
| --config string                                                                                                    |
| The kubelet will load its initial configuration from this file. The path may be absolute or relative; relative pat |
| --config-dir string   Default: "                                                                                   |
| Path to a directory to specify drop-ins, allows the user to optionally specify additional configs to overwrite v   |
| <b>Note:</b> Set the 'KUBELET_CONFIG_DROPIN_DIR_ALPHA' environment variable to specify the directory.              |
| --container-log-max-files int32   Default: 5                                                                       |
| <Warning: Beta feature> Set the maximum number of container log files that can be present for a container.         |
| --container-log-max-size string   Default: 10Mi                                                                    |
| <Warning: Beta feature> Set the maximum size (e.g. 10Mi) of container log file before it is rotated. (DEPREC       |
| --container-runtime-endpoint string   Default: "unix:///run/containerd/containerd.sock"                            |
| The endpoint of remote runtime service. UNIX domain sockets are supported on Linux, while 'npipe' and 'tcp         |
| --contention-profiling                                                                                             |
| Enable block profiling, if profiling is enabled. (DEPRECATED: This parameter should be set via the config fil      |
| --cpu-cfs-quota   Default: true                                                                                    |
| Enable CPU CFS quota enforcement for containers that specify CPU limits. (DEPRECATED: This parameter               |
| --cpu-cfs-quota-period duration   Default: 100ms                                                                   |
| Sets CPU CFS quota period value, cpu.cfs_period_us, defaults to Linux Kernel default. (DEPRECATED: This            |
| --cpu-manager-policy string   Default: none                                                                        |
| The CPU manager policy to use. Possible values: "none", "static". (DEPRECATED: This parameter should be s          |
| --cpu-manager-policy-options string                                                                                |
| A set of 'key=value' CPU manager policy options to use, to fine tune their behaviour. If not supplied, keep th     |
| --cpu-manager-reconcile-period duration   Default: 10s                                                             |
| <Warning: Alpha feature> CPU manager reconciliation period. Examples: "10s", or "1m". If not supplied, defa        |
| --enable-controller-attach-detach   Default: true                                                                  |
| Enables the Attach/Detach controller to manage attachment/detachment of volumes scheduled to this node,            |
| --enable-debugging-handlers   Default: true                                                                        |
| Enables server endpoints for log collection and local running of containers and commands. (DEPRECATED:             |
| --enable-server   Default: true                                                                                    |
| Enable the kubelet's server. (DEPRECATED: This parameter should be set via the config file specified by the        |
| --enforce-node-allocatable strings   Default: pods                                                                 |
| A comma separated list of levels of node allocatable enforcement to be enforced by kubelet. Acceptable optio       |
| --event-burst int32   Default: 100                                                                                 |
| Maximum size of a bursty event records, temporarily allows event records to burst to this number, while stil       |
| --event-qps int32   Default: 50                                                                                    |
| QPS to limit event creations. The number must be >= 0. If 0 will use default QPS (50). (DEPRECATED: This p         |
| --eviction-hard strings   Default: imagefs.available<15%,memory.available<100Mi,nodefs.available<10%               |
| A set of eviction thresholds (e.g. "memory.available<1Gi") that if met would trigger a pod eviction. On a Linu     |
| --eviction-max-pod-grace-period int32                                                                              |
| Maximum allowed grace period (in seconds) to use when terminating pods in response to a soft eviction thro         |
| --eviction-minimum-reclaim strings                                                                                 |
| A set of minimum reclaims (e.g. "imagefs.available=2Gi") that describes the minimum amount of resource th          |
| --eviction-pressure-transition-period duration   Default: 5m0s                                                     |

|                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Duration for which the kubelet has to wait before transitioning out of an eviction pressure condition. (DEPRECATED)                                                 |
| --eviction-soft strings                                                                                                                                             |
| A set of eviction thresholds (e.g. "memory.available<1.5Gi") that if met over a corresponding grace period will trigger an eviction                                 |
| --eviction-soft-grace-period strings                                                                                                                                |
| A set of eviction grace periods (e.g. "memory.available=1m30s") that correspond to how long a soft eviction threshold can be violated before triggering an eviction |
| --exit-on-lock-contention                                                                                                                                           |
| Whether kubelet should exit upon lock-file contention.                                                                                                              |
| --experimental-allocatable-ignore-eviction Default: false                                                                                                           |
| When set to true, hard eviction thresholds will be ignored while calculating node allocatable. See <a href="#">here</a> for more details                            |
| --experimental-mounter-path string Default: mount                                                                                                                   |
| [Experimental] Path of mounter binary. Leave empty to use the default mount. (DEPRECATED: will be removed in 1.15)                                                  |
| --fail-swap-on Default: true                                                                                                                                        |
| Makes the kubelet fail to start if swap is enabled on the node. (DEPRECATED: This parameter should be set to false)                                                 |
| --feature-gates <A list of 'key=true/false' pairs>                                                                                                                  |
| A set of key=value pairs that describe feature gates for alpha/experimental features. Options are:                                                                  |
| APIResponseCompression=true false (BETA - default=true)                                                                                                             |
| APIServerIdentity=true false (BETA - default=true)                                                                                                                  |
| APIServerTracing=true false (BETA - default=true)                                                                                                                   |
| APIServingWithRoutine=true false (BETA - default=true)                                                                                                              |
| AllAlpha=true false (ALPHA - default=false)                                                                                                                         |
| AllBeta=true false (BETA - default=false)                                                                                                                           |
| AnyVolumeDataSource=true false (BETA - default=true)                                                                                                                |
| AppArmor=true false (BETA - default=true)                                                                                                                           |
| AppArmorFields=true false (BETA - default=true)                                                                                                                     |
| CPUManagerPolicyAlphaOptions=true false (ALPHA - default=false)                                                                                                     |
| CPUManagerPolicyBetaOptions=true false (BETA - default=true)                                                                                                        |
| CPUManagerPolicyOptions=true false (BETA - default=true)                                                                                                            |
| CRDValidationRatcheting=true false (BETA - default=true)                                                                                                            |
| CSIMigrationPortworx=true false (BETA - default=false)                                                                                                              |
| CSIVolumeHealth=true false (ALPHA - default=false)                                                                                                                  |

| help for kubelet                                                                                                                   |
| --hostname-override string                                                                                                         |
| If non-empty, will use this string as identification instead of the actual hostname. If --cloud-provider is set, the               |
| --http-check-frequency duration    Default: 20s                                                                                    |
| Duration between checking HTTP for new data. (DEPRECATED: This parameter should be set via the config file)                        |
| --image-credential-provider-bin-dir string                                                                                         |
| The path to the directory where credential provider plugin binaries are located.                                                   |
| --image-credential-provider-config string                                                                                          |
| The path to the credential provider plugin config file.                                                                            |
| --image-gc-high-threshold int32    Default: 85                                                                                     |
| The percent of disk usage after which image garbage collection is always run. Values must be within the range [1, 100]             |
| --image-gc-low-threshold int32    Default: 80                                                                                      |
| The percent of disk usage before which image garbage collection is never run. Lowest disk usage to garbage collect                 |
| --image-service-endpoint string                                                                                                    |
| The endpoint of remote image service. If not specified, it will be the same with --container-runtime-endpoint                      |
| --keep-terminated-pod-volumes                                                                                                      |
| Keep terminated pod volumes mounted to the node after the pod terminates. Can be useful for debugging volumes                      |
| --kernel-memcg-notification                                                                                                        |
| If enabled, the kubelet will integrate with the kernel memcg notification to determine if memory eviction threshold                |
| --kube-api-burst int32    Default: 100                                                                                             |
| Burst to use while talking with kubernetes API server. The number must be >= 0. If 0 will use default burst (100)                  |
| --kube-api-content-type string    Default: application/vnd.kubernetes.protobuf                                                     |
| Content type of requests sent to apiserver. (DEPRECATED: This parameter should be set via the config file)                         |
| --kube-api-qps int32    Default: 50                                                                                                |
| QPS to use while talking with kubernetes API server. The number must be >= 0. If 0 will use default QPS (50)                       |
| --kube-reserved strings    Default: <None>                                                                                         |
| A set of <resource name>=<resource quantity> (e.g. "cpu=200m,memory=500Mi,ephemeral-storage=1Gi,pid=1000")                         |
| --kube-reserved-cgroup string    Default: "                                                                                        |
| Absolute name of the top level cgroup that is used to manage kubernetes components for which compute resource                      |
| --kubeconfig string                                                                                                                |
| Path to a kubeconfig file, specifying how to connect to the API server. Providing --kubeconfig enables API server                  |
| --kubelet-cgroups string                                                                                                           |
| Optional absolute name of cgroups to create and run the kubelet in. (DEPRECATED: This parameter should be set via the config file) |
| --local-storage-capacity-isolation>    Default: true                                                                               |
| If true, local ephemeral storage isolation is enabled. Otherwise, local storage isolation feature will be disabled                 |
| --lock-file string                                                                                                                 |
| <Warning: Alpha feature> The path to file for kubelet to use as a lock file.                                                       |
| --log-flush-frequency duration    Default: 5s                                                                                      |
| Maximum number of seconds between log flushes.                                                                                     |
| --log-json-info-buffer-size string    Default: '0'                                                                                 |
| [Alpha] In JSON format with split output streams, the info messages can be buffered for a while to increase performance            |
| --log-json-split-stream                                                                                                            |
| [Alpha] In JSON format, write error messages to stderr and info messages to stdout. The default is to write all                    |
| --log-text-info-buffer-size string    Default: '0'                                                                                 |

|                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [Alpha] In text format with split output streams, the info messages can be buffered for a while to increase performance.                                                        |
| --log-text-split-stream                                                                                                                                                         |
| [Alpha] In text format, write error messages to stderr and info messages to stdout. The default is to write a single log message to stderr.                                     |
| --logging-format string    Default: text                                                                                                                                        |
| Sets the log format. Permitted formats: "json" (gated by LoggingBetaOptions, "text"). (DEPRECATED: This parameter should be set via the config file)                            |
| --make-iptables-util-chains    Default: true                                                                                                                                    |
| If true, kubelet will ensure iptables utility rules are present on host. (DEPRECATED: This parameter should be set via the config file)                                         |
| --manifest-url string                                                                                                                                                           |
| URL for accessing additional Pod specifications to run. (DEPRECATED: This parameter should be set via the config file)                                                          |
| --manifest-url-header strings                                                                                                                                                   |
| Comma-separated list of HTTP headers to use when accessing the URL provided to --manifest-url. Multiple headers can be specified.                                               |
| --max-open-files int    Default: 1000000                                                                                                                                        |
| Number of files that can be opened by kubelet process. (DEPRECATED: This parameter should be set via the config file)                                                           |
| --max-pods int32    Default: 110                                                                                                                                                |
| Number of Pods that can run on this kubelet. (DEPRECATED: This parameter should be set via the config file)                                                                     |
| --maximum-dead-containers int32    Default: -1                                                                                                                                  |
| Maximum number of old instances of containers to retain globally. Each container takes up some disk space.                                                                      |
| --maximum-dead-containers-per-container int32    Default: 1                                                                                                                     |
| Maximum number of old instances to retain per container. Each container takes up some disk space. (DEPRECATED: This parameter should be set via the config file)                |
| --memory-manager-policy string    Default: None                                                                                                                                 |
| Memory Manager policy to use. Possible values: "None", "Static". (DEPRECATED: This parameter should be set via the config file)                                                 |
| --minimum-container-ttl-duration duration                                                                                                                                       |
| Minimum age for a finished container before it is garbage collected. Examples: "300ms", "10s" or "2h45m". (DEPRECATED: This parameter should be set via the config file)        |
| --minimum-image-ttl-duration duration    Default: 2m0s                                                                                                                          |
| Minimum age for an unused image before it is garbage collected. Examples: "300ms", "10s" or "2h45m". (DEPRECATED: This parameter should be set via the config file)             |
| --node-ip string                                                                                                                                                                |
| IP address (or comma-separated dual-stack IP addresses) of the node. If unset, kubelet will use the node's default IP address.                                                  |
| --node-labels <key=value pairs>                                                                                                                                                 |
| <Warning: Alpha feature>Labels to add when registering the node in the cluster. Labels must be key=value pairs.                                                                 |
| --node-status-max-images int32    Default: 50                                                                                                                                   |
| The maximum number of images to report in node.status.images. If -1 is specified, no cap will be applied. (DEPRECATED: This parameter should be set via the config file)        |
| --node-status-update-frequency duration    Default: 10s                                                                                                                         |
| Specifies how often kubelet posts node status to master. <b>Note:</b> be cautious when changing the constant, it may affect the cluster's health.                               |
| --oom-score-adj int32    Default: -999                                                                                                                                          |
| The oom-score-adj value for kubelet process. Values must be within the range [-1000, 1000]. (DEPRECATED: This parameter should be set via the config file)                      |
| --pod-cidr string                                                                                                                                                               |
| The CIDR to use for pod IP addresses, only used in standalone mode. In cluster mode, this is obtained from the kube-apiserver.                                                  |
| --pod-infra-container-image string    Default: registry.k8s.io/pause:3.9                                                                                                        |
| Specified image will not be pruned by the image garbage collector. CRI implementations have their own container image garbage collection.                                       |
| --pod-manifest-path string                                                                                                                                                      |
| Path to the directory containing static pod files to run, or the path to a single static pod file. Files starting with "kubeletconfig-" are reserved for kubelet configuration. |
| --pod-max-pids int    Default: -1                                                                                                                                               |
| Set the maximum number of processes per pod. If -1, the kubelet defaults to the node allocatable PID capacity.                                                                  |
| --pods-per-core int32                                                                                                                                                           |
| Number of Pods per core that can run on this kubelet. The total number of pods on this kubelet cannot exceed the number of cores on the node.                                   |

|                                                                                                                                                                                                 |                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --port int32                                                                                                                                                                                    | Default: 10250            |
| The port for the kubelet to serve on. (DEPRECATED: This parameter should be set via the config file specified by --config)                                                                      |                           |
| --protect-kernel-defaults                                                                                                                                                                       |                           |
| Default kubelet behaviour for kernel tuning. If set, kubelet errors if any of kernel tunables is different than kernel default                                                                  |                           |
| --provider-id string                                                                                                                                                                            |                           |
| Unique identifier for identifying the node in a machine database, i.e cloud provider.                                                                                                           |                           |
| --qos-reserved string                                                                                                                                                                           |                           |
| <Warning: Alpha feature> A set of <resource name>=<percentage> (e.g. "memory=50%") pairs that describe reserved resources for QoS                                                               |                           |
| --read-only-port int32                                                                                                                                                                          | Default: 10255            |
| The read-only port for the kubelet to serve on with no authentication/authorization (set to 0 to disable). (DEPRECATED: This parameter should be set via the config file specified by --config) |                           |
| --register-node                                                                                                                                                                                 | Default: true             |
| Register the node with the API server. If --kubeconfig is not provided, this flag is irrelevant, as the kubelet will attempt to register with the default endpoint                              |                           |
| --register-schedulable                                                                                                                                                                          | Default: true             |
| Register the node as schedulable. Won't have any effect if --register-node is false. (DEPRECATED: will be removed in 1.10)                                                                      |                           |
| --register-with-taints string                                                                                                                                                                   |                           |
| Register the node with the given list of taints (comma separated <key>=<value>:<effect>). No-op if --register-node is false                                                                     |                           |
| --registry-burst int32                                                                                                                                                                          | Default: 10               |
| Maximum size of a bursty pulls, temporarily allows pulls to burst to this number, while still not exceeding --registry-qps                                                                      |                           |
| --registry-qps int32                                                                                                                                                                            | Default: 5                |
| If > 0, limit registry pull QPS to this value. If 0, unlimited. (DEPRECATED: This parameter should be set via the config file specified by --config)                                            |                           |
| --reserved-cpus string                                                                                                                                                                          |                           |
| A comma-separated list of CPUs or CPU ranges that are reserved for system and kubernetes usage. This specification is in the same format as the cgroup v1 cpu.shares value                      |                           |
| --reserved-memory string                                                                                                                                                                        |                           |
| A comma-separated list of memory reservations for NUMA nodes. (e.g. "--reserved-memory 0:memory=1Gi,1:memory=2Gi")                                                                              |                           |
| --resolv-conf string                                                                                                                                                                            | Default: /etc/resolv.conf |
| Resolver configuration file used as the basis for the container DNS resolution configuration. (DEPRECATED: This parameter should be set via the config file specified by --config)              |                           |
| --root-dir string                                                                                                                                                                               | Default: /var/lib/kubelet |
| Directory path for managing kubelet files (volume mounts, etc).                                                                                                                                 |                           |
| --rotate-certificates                                                                                                                                                                           |                           |
| Auto rotate the kubelet client certificates by requesting new certificates from the kube-apiserver when the certificates are close to expiration                                                |                           |
| --rotate-server-certificates                                                                                                                                                                    |                           |
| Auto-request and rotate the kubelet serving certificates by requesting new certificates from the kube-apiserver when the certificates are close to expiration                                   |                           |
| --runonce                                                                                                                                                                                       |                           |
| If true, exit after spawning pods from local manifests or remote urls. Exclusive with --enable-server (DEPRECATED: This parameter should be set via the config file specified by --config)      |                           |
| --runtime-cgroups string                                                                                                                                                                        |                           |
| Optional absolute name of cgroups to create and run the runtime in.                                                                                                                             |                           |
| --runtime-request-timeout duration                                                                                                                                                              | Default: 2m0s             |
| Timeout of all runtime requests except long running request - pull, logs, exec and attach. When timeout expires, the request is cancelled                                                       |                           |
| --seccomp-default                                                                                                                                                                               |                           |
| Enable the use of RuntimeDefault as the default seccomp profile for all workloads.                                                                                                              |                           |
| --serialize-image-pulls                                                                                                                                                                         | Default: true             |
| Pull images one at a time. We recommend *not* changing the default value on nodes that run docker daemon                                                                                        |                           |
| --streaming-connection-idle-timeout duration                                                                                                                                                    | Default: 4h0m0s           |
| Maximum time a streaming connection can be idle before the connection is automatically closed. 0 indicates no timeout                                                                           |                           |

| Comma-separated list of pattern=N settings for file-filtered logging (only works for text log format).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| --volume-plugin-dir string   Default: /usr/libexec/kubernetes/kubelet-plugins/volume/exec/                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| The full path of the directory in which to search for additional third party volume plugins. (DEPRECATED: This parameter should be set via the config file specified by the kubelet's --config flag. See <a href="#">kubelet documentation</a> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| --volume-stats-aggr-period duration   Default: 1m0s                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Specifies interval for kubelet to calculate and cache the volume disk usage for all pods and volumes. To disable, set to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# kube-apiserver

## Synopsis

The Kubernetes API server validates and configures data for the api objects which include pods, services, replicationcontrollers, and others. The API Server services REST operations and provides the frontend to the cluster's shared state through which all other components interact.

kube-apiserver [flags]

# Options

|                                                                                                                                                                                                                                                                                                                            |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <code>--admission-control-config-file</code> string                                                                                                                                                                                                                                                                        |  |
| File with admission control configuration.                                                                                                                                                                                                                                                                                 |  |
| <code>--advertise-address</code> string                                                                                                                                                                                                                                                                                    |  |
| The IP address on which to advertise the apiserver to members of the cluster. This address must be reachable by the rest of the cluster. If blank, the <code>--bind-address</code> will be used. If <code>--bind-address</code> is unspecified, the host's default interface will be used.                                 |  |
| <code>--aggregator-reject-forwarding-redirect</code> Default: true                                                                                                                                                                                                                                                         |  |
| Aggregator reject forwarding redirect response back to client.                                                                                                                                                                                                                                                             |  |
| <code>--allow-metric-labels</code> stringToString    Default: []                                                                                                                                                                                                                                                           |  |
| The map from metric-label to value allow-list of this label. The key's format is <code>&lt;MetricName&gt;,&lt;LabelName&gt;</code> . The value's format is <code>&lt;allowed_value&gt;,&lt;allowed_value&gt;...e.g. metric1,label1='v1,v2,v3', metric1,label2='v1,v2,v3' metric2,label1='v1,v2,v3'</code> .                |  |
| <code>--allow-metric-labels-manifest</code> string                                                                                                                                                                                                                                                                         |  |
| The path to the manifest file that contains the allow-list mapping. The format of the file is the same as the flag <code>--allow-metric-labels</code> . Note that the flag <code>--allow-metric-labels</code> will override the manifest file.                                                                             |  |
| <code>--allow-privileged</code>                                                                                                                                                                                                                                                                                            |  |
| If true, allow privileged containers. [default=false]                                                                                                                                                                                                                                                                      |  |
| <code>--anonymous-auth</code> Default: true                                                                                                                                                                                                                                                                                |  |
| Enables anonymous requests to the secure port of the API server. Requests that are not rejected by another authentication method are treated as anonymous requests. Anonymous requests have a username of <code>system:anonymous</code> , and a group name of <code>system:unauthenticated</code> .                        |  |
| <code>--api-audiences</code> strings                                                                                                                                                                                                                                                                                       |  |
| Identifiers of the API. The service account token authenticator will validate that tokens used against the API are bound to at least one of these audiences. If the <code>--service-account-issuer</code> flag is configured and this flag is not, this field defaults to a single element list containing the issuer URL. |  |
| <code>--audit-log-batch-buffer-size</code> int    Default: 10000                                                                                                                                                                                                                                                           |  |
| The size of the buffer to store events before batching and writing. Only used in batch mode.                                                                                                                                                                                                                               |  |
| <code>--audit-log-batch-max-size</code> int    Default: 1                                                                                                                                                                                                                                                                  |  |

|                                                          |                                                                                                                                                                                                                         |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                          | The maximum size of a batch. Only used in batch mode.                                                                                                                                                                   |
| <code>--audit-log-batch-max-wait duration</code>         |                                                                                                                                                                                                                         |
|                                                          | The amount of time to wait before force writing the batch that hadn't reached the max size. Only used in batch mode.                                                                                                    |
| <code>--audit-log-batch-throttle-burst int</code>        |                                                                                                                                                                                                                         |
|                                                          | Maximum number of requests sent at the same moment if ThrottleQPS was not utilized before. Only used in batch mode.                                                                                                     |
| <code>--audit-log-batch-throttle-enable</code>           |                                                                                                                                                                                                                         |
|                                                          | Whether batching throttling is enabled. Only used in batch mode.                                                                                                                                                        |
| <code>--audit-log-batch-throttle-qps float</code>        |                                                                                                                                                                                                                         |
|                                                          | Maximum average number of batches per second. Only used in batch mode.                                                                                                                                                  |
| <code>--audit-log-compress</code>                        |                                                                                                                                                                                                                         |
|                                                          | If set, the rotated log files will be compressed using gzip.                                                                                                                                                            |
| <code>--audit-log-format string</code> Default: "json"   |                                                                                                                                                                                                                         |
|                                                          | Format of saved audits. "legacy" indicates 1-line text format for each event. "json" indicates structured json format. Known formats are legacy,json.                                                                   |
| <code>--audit-log-maxage int</code>                      |                                                                                                                                                                                                                         |
|                                                          | The maximum number of days to retain old audit log files based on the timestamp encoded in their filename.                                                                                                              |
| <code>--audit-log-maxbackup int</code>                   |                                                                                                                                                                                                                         |
|                                                          | The maximum number of old audit log files to retain. Setting a value of 0 will mean there's no restriction on the number of files.                                                                                      |
| <code>--audit-log-maxsize int</code>                     |                                                                                                                                                                                                                         |
|                                                          | The maximum size in megabytes of the audit log file before it gets rotated.                                                                                                                                             |
| <code>--audit-log-mode string</code> Default: "blocking" |                                                                                                                                                                                                                         |
|                                                          | Strategy for sending audit events. Blocking indicates sending events should block server responses. Batch causes the backend to buffer and write events asynchronously. Known modes are batch,blocking,blocking-strict. |
| <code>--audit-log-path string</code>                     |                                                                                                                                                                                                                         |

|                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If set, all requests coming to the apiserver will be logged to this file. '-' means standard out.                                                                                                                            |
| --audit-log-truncate-enabled                                                                                                                                                                                                 |
| Whether event and batch truncating is enabled.                                                                                                                                                                               |
| --audit-log-truncate-max-batch-size int    Default: 10485760                                                                                                                                                                 |
| Maximum size of the batch sent to the underlying backend. Actual serialized size can be several hundreds of bytes greater. If a batch exceeds this limit, it is split into several batches of smaller size.                  |
| --audit-log-truncate-max-event-size int    Default: 102400                                                                                                                                                                   |
| Maximum size of the audit event sent to the underlying backend. If the size of an event is greater than this number, first request and response are removed, and if this doesn't reduce the size enough, event is discarded. |
| --audit-log-version string    Default: "audit.k8s.io/v1"                                                                                                                                                                     |
| API group and version used for serializing audit events written to log.                                                                                                                                                      |
| --audit-policy-file string                                                                                                                                                                                                   |
| Path to the file that defines the audit policy configuration.                                                                                                                                                                |
| --audit-webhook-batch-buffer-size int    Default: 10000                                                                                                                                                                      |
| The size of the buffer to store events before batching and writing. Only used in batch mode.                                                                                                                                 |
| --audit-webhook-batch-max-size int    Default: 400                                                                                                                                                                           |
| The maximum size of a batch. Only used in batch mode.                                                                                                                                                                        |
| --audit-webhook-batch-max-wait duration    Default: 30s                                                                                                                                                                      |
| The amount of time to wait before force writing the batch that hadn't reached the max size. Only used in batch mode.                                                                                                         |
| --audit-webhook-batch-throttle-burst int    Default: 15                                                                                                                                                                      |
| Maximum number of requests sent at the same moment if ThrottleQPS was not utilized before. Only used in batch mode.                                                                                                          |
| --audit-webhook-batch-throttle-enable    Default: true                                                                                                                                                                       |
| Whether batching throttling is enabled. Only used in batch mode.                                                                                                                                                             |
| --audit-webhook-batch-throttle-qps float    Default: 10                                                                                                                                                                      |

|                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Maximum average number of batches per second. Only used in batch mode.                                                                                                                                                                                                                    |
| --audit-webhook-config-file string                                                                                                                                                                                                                                                        |
| Path to a kubeconfig formatted file that defines the audit webhook configuration.                                                                                                                                                                                                         |
| --audit-webhook-initial-backoff duration    Default: 10s                                                                                                                                                                                                                                  |
| The amount of time to wait before retrying the first failed request.                                                                                                                                                                                                                      |
| --audit-webhook-mode string    Default: "batch"                                                                                                                                                                                                                                           |
| Strategy for sending audit events. Blocking indicates sending events should block server responses. Batch causes the backend to buffer and write events asynchronously. Known modes are batch,blocking,blocking-strict.                                                                   |
| --audit-webhook-truncate-enabled                                                                                                                                                                                                                                                          |
| Whether event and batch truncating is enabled.                                                                                                                                                                                                                                            |
| --audit-webhook-truncate-max-batch-size int    Default: 10485760                                                                                                                                                                                                                          |
| Maximum size of the batch sent to the underlying backend. Actual serialized size can be several hundreds of bytes greater. If a batch exceeds this limit, it is split into several batches of smaller size.                                                                               |
| --audit-webhook-truncate-max-event-size int    Default: 102400                                                                                                                                                                                                                            |
| Maximum size of the audit event sent to the underlying backend. If the size of an event is greater than this number, first request and response are removed, and if this doesn't reduce the size enough, event is discarded.                                                              |
| --audit-webhook-version string    Default: "audit.k8s.io/v1"                                                                                                                                                                                                                              |
| API group and version used for serializing audit events written to webhook.                                                                                                                                                                                                               |
| --authentication-config string                                                                                                                                                                                                                                                            |
| File with Authentication Configuration to configure the JWT Token authenticator. Note: This feature is in Alpha since v1.29.--feature-gate=StructuredAuthenticationConfiguration=true needs to be set for enabling this feature.This feature is mutually exclusive with the oidc-* flags. |
| --authentication-token-webhook-cache-ttl duration    Default: 2m0s                                                                                                                                                                                                                        |
| The duration to cache responses from the webhook token authenticator.                                                                                                                                                                                                                     |
| --authentication-token-webhook-config-file string                                                                                                                                                                                                                                         |
| File with webhook configuration for token authentication in kubeconfig format. The API server will query the remote service to determine authentication for bearer tokens.                                                                                                                |

|                                                                                                                                                                                                                                                                                                                                                             |                                |

| Number of workers spawned for DeleteCollection call. These are used to speed up namespace cleanup.                                                                                                                                                                                                                                                                                                                                                                                   |
| --disable-admission-plugins strings                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| admission plugins that should be disabled although they are in the default enabled plugins list (NamespaceLifecycle, LimitRanger, ServiceAccount, TaintNodesByCondition, PodSecurity, Priority, DefaultTolerationSeconds, DefaultStorageClass, StorageObjectInUseProtection, PersistentVolumeClaimResize, RuntimeClass, CertificateApproval, CertificateSigning,                                                                                                                     |

ClusterTrustBundleAttest, CertificateSubjectRestriction, DefaultIngressClass, MutatingAdmissionWebhook, ValidatingAdmissionPolicy, ValidatingAdmissionWebhook, ResourceQuota). Comma-delimited list of admission plugins: AlwaysAdmit, AlwaysDeny, AlwaysPullImages, CertificateApproval, CertificateSigning, CertificateSubjectRestriction, ClusterTrustBundleAttest, DefaultIngressClass, DefaultStorageClass, DefaultTolerationSeconds, DenyServiceExternalIPs, EventRateLimit, ExtendedResourceToleration, ImagePolicyWebhook, LimitPodHardAntiAffinityTopology, LimitRanger, MutatingAdmissionWebhook, NamespaceAutoProvision, NamespaceExists, NamespaceLifecycle, NodeRestriction, OwnerReferencesPermissionEnforcement, PersistentVolumeClaimResize, PersistentVolumeLabel, PodNodeSelector, PodSecurity, PodTolerationRestriction, Priority, ResourceQuota, RuntimeClass, ServiceAccount, StorageObjectInUseProtection, TaintNodesByCondition, ValidatingAdmissionPolicy, ValidatingAdmissionWebhook. The order of plugins in this flag does not matter.

#### --disabled-metrics strings

This flag provides an escape hatch for misbehaving metrics. You must provide the fully qualified metric name in order to disable it. Disclaimer: disabling metrics is higher in precedence than showing hidden metrics.

#### --egress-selector-config-file string

File with apiserver egress selector configuration.

#### --enable-admission-plugins strings

admission plugins that should be enabled in addition to default enabled ones (NamespaceLifecycle, LimitRanger, ServiceAccount, TaintNodesByCondition, PodSecurity, Priority, DefaultTolerationSeconds, DefaultStorageClass, StorageObjectInUseProtection, PersistentVolumeClaimResize, RuntimeClass, CertificateApproval, CertificateSigning, ClusterTrustBundleAttest, CertificateSubjectRestriction, DefaultIngressClass, MutatingAdmissionWebhook, ValidatingAdmissionPolicy, ValidatingAdmissionWebhook, ResourceQuota). Comma-delimited list of admission plugins: AlwaysAdmit, AlwaysDeny, AlwaysPullImages, CertificateApproval, CertificateSigning, CertificateSubjectRestriction, ClusterTrustBundleAttest, DefaultIngressClass, DefaultStorageClass, DefaultTolerationSeconds, DenyServiceExternalIPs, EventRateLimit, ExtendedResourceToleration, ImagePolicyWebhook, LimitPodHardAntiAffinityTopology, LimitRanger, MutatingAdmissionWebhook, NamespaceAutoProvision, NamespaceExists, NamespaceLifecycle, NodeRestriction, OwnerReferencesPermissionEnforcement, PersistentVolumeClaimResize, PersistentVolumeLabel, PodNodeSelector, PodSecurity, PodTolerationRestriction, Priority, ResourceQuota, RuntimeClass, ServiceAccount, StorageObjectInUseProtection, TaintNodesByCondition, ValidatingAdmissionPolicy, ValidatingAdmissionWebhook. The order of plugins in this flag does not matter.

#### --enable-aggregator-routing

Turns on aggregator routing requests to endpoints IP rather than cluster IP.

#### --enable-bootstrap-token-auth

|                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable to allow secrets of type 'bootstrap.kubernetes.io/token' in the 'kube-system' namespace to be used for TLS bootstrapping authentication.                                                                                                    |
| --enable-garbage-collector    Default: true                                                                                                                                                                                                        |
| Enables the generic garbage collector. MUST be synced with the corresponding flag of the kube-controller-manager.                                                                                                                                  |
| --enable-priority-and-fairness    Default: true                                                                                                                                                                                                    |
| If true, replace the max-in-flight handler with an enhanced one that queues and dispatches with priority and fairness                                                                                                                              |
| --encryption-provider-config string                                                                                                                                                                                                                |
| The file containing configuration for encryption providers to be used for storing secrets in etcd                                                                                                                                                  |
| --encryption-provider-config-automatic-reload                                                                                                                                                                                                      |
| Determines if the file set by --encryption-provider-config should be automatically reloaded if the disk contents change. Setting this to true disables the ability to uniquely identify distinct KMS plugins via the API server healthz endpoints. |
| --endpoint-reconciler-type string    Default: "lease"                                                                                                                                                                                              |
| Use an endpoint reconciler (master-count, lease, none) master-count is deprecated, and will be removed in a future version.                                                                                                                        |
| --etcd-cafile string                                                                                                                                                                                                                               |
| SSL Certificate Authority file used to secure etcd communication.                                                                                                                                                                                  |
| --etcd-certfile string                                                                                                                                                                                                                             |
| SSL certification file used to secure etcd communication.                                                                                                                                                                                          |
| --etcd-compaction-interval duration    Default: 5m0s                                                                                                                                                                                               |
| The interval of compaction requests. If 0, the compaction request from apiserver is disabled.                                                                                                                                                      |
| --etcd-count-metric-poll-period duration    Default: 1m0s                                                                                                                                                                                          |
| Frequency of polling etcd for number of resources per type. 0 disables the metric collection.                                                                                                                                                      |
| --etcd-db-metric-poll-interval duration    Default: 30s                                                                                                                                                                                            |
| The interval of requests to poll etcd and update metric. 0 disables the metric collection                                                                                                                                                          |
| --etcd-healthcheck-timeout duration    Default: 2s                                                                                                                                                                                                 |

|                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| To prevent HTTP/2 clients from getting stuck on a single apiserver, randomly close a connection (GOAWAY). The client's other in-flight requests won't be affected, and the client will reconnect, likely landing on a different apiserver after going through the load balancer again. This argument sets the fraction of requests that will be sent a GOAWAY. Clusters with single apiservers, or which don't use a load balancer, should NOT enable this. Min is 0 (off), Max is .02 (1/50 requests); .001 (1/1000) is a recommended starting point.                                         |

| --service-account-extend-token-expiration    Default: true                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Turns on projected service account expiration extension during token generation, which helps safe transition from legacy token to bound service account token feature. If this flag is enabled, admission injected tokens would be extended up to 1 year to prevent unexpected failure during transition, ignoring value of service-account-max-token-expiration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| --service-account-issuer strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Identifier of the service account token issuer. The issuer will assert this identifier in "iss" claim of issued tokens. This value is a string or URI. If this option is not a valid URI per the OpenID Discovery 1.0 spec, the ServiceAccountIssuerDiscovery feature will remain disabled, even if the feature gate is set to true. It is highly recommended that this value comply with the OpenID spec: <a href="https://openid.net/specs/openid-connect-discovery-1_0.html">https://openid.net/specs/openid-connect-discovery-1_0.html</a> . In practice, this means that service-account-issuer must be an https URL. It is also highly recommended that this URL be capable of serving OpenID discovery documents at {service-account-issuer}/.well-known/openid-configuration. When this flag is specified multiple times, the first is used to generate tokens and all are used to determine which issuers are accepted. |
| --service-account-jwks-uri string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Overrides the URI for the JSON Web Key Set in the discovery doc served at /.well-known/openid-configuration. This flag is useful if the discovery doc and key set are served to relying parties from a URL other than the API server's external (as auto-detected or overridden with external-hostname).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Path to the file that contains the current private key of the service account token issuer. The issuer will sign issued ID tokens with this private key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --service-cluster-ip-range string                                               | A CIDR notation IP range from which to assign service cluster IPs. This must not overlap with any IP ranges assigned to nodes or pods. Max of two dual-stack CIDRs is allowed.                                                                                                                                                                                                                                  |
| --service-node-port-range <a string in the form 'N1-N2'>   Default: 30000-32767 | A port range to reserve for services with NodePort visibility. This must not overlap with the ephemeral port range on nodes. Example: '30000-32767'. Inclusive at both ends of the range.                                                                                                                                                                                                                       |
| --show-hidden-metrics-for-version string                                        | The previous version for which you want to show hidden metrics. Only the previous minor version is meaningful, other values will not be allowed. The format is <major>.<minor>, e.g.: '1.16'. The purpose of this format is make sure you have the opportunity to notice if the next release hides additional metrics, rather than being surprised when they are permanently removed in the release after that. |
| --shutdown-delay-duration duration                                              | Time to delay the termination. During that time the server keeps serving requests normally. The endpoints /healthz and /livez will return success, but /readyz immediately returns failure. Graceful termination starts after this delay has elapsed. This can be used to allow load balancer to stop sending traffic to this server.                                                                           |
| --shutdown-send-retry-after                                                     | If true the HTTP Server will continue listening until all non long running request(s) in flight have been drained, during this window all incoming requests will be rejected with a status code 429 and a 'Retry-After' response header, in addition 'Connection: close' response header is set in order to tear down the TCP connection when idle.                                                             |
| --shutdown-watch-termination-grace-period duration                              | This option, if set, represents the maximum amount of grace period the apiserver will wait for active watch request(s) to drain during the graceful server shutdown window.                                                                                                                                                                                                                                     |
| --storage-backend string                                                        | The storage backend for persistence. Options: 'etcd3' (default).                                                                                                                                                                                                                                                                                                                                                |
| --storage-media-type string   Default: "application/vnd.kubernetes.protobuf"    | The media type to use to store objects in storage. Some resources or storage backends may only support a specific media type and will ignore this setting. Supported media types: [application/json, application/yaml, application/vnd.kubernetes.protobuf]                                                                                                                                                     |
| --strict-transport-security-directives strings                                  | List of directives for HSTS, comma separated. If this list is empty, then HSTS directives will not be added. Example: 'max-age=31536000,includeSubDomains,preload'                                                                                                                                                                                                                                              |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --tls-cert-file string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <p>File containing the default x509 Certificate for HTTPS. (CA cert, if any, concatenated after server cert). If HTTPS serving is enabled, and --tls-cert-file and --tls-private-key-file are not provided, a self-signed certificate and key are generated for the public address and saved to the directory specified by --cert-dir.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| --tls-cipher-suites strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A pair of x509 certificate and private key file paths, optionally suffixed with a list of domain patterns which are fully qualified domain names, possibly with prefixed wildcard segments. The domain patterns also allow IP addresses, but IPs should only be used if the apiserver has visibility to the IP address requested by a client. If no domain patterns are provided, the names of the certificate are extracted. Non-wildcard matches trump over wildcard matches, explicit domain patterns trump over extracted names. For multiple key/certificate pairs, use the --tls-sni-cert-key multiple times. Examples: "example.crt,example.key" or "foo.crt,foo.key:*.foo.com,foo.com".                                |

| --watch-cache     Default: true                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Enable watch caching in the apiserver                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --watch-cache-sizes strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Watch cache size settings for some resources (pods, nodes, etc.), comma separated. The individual setting format: resource[.group]#size, where resource is lowercase plural (no version), group is omitted for resources of apiVersion v1 (the legacy core API) and included for others, and size is a number. This option is only meaningful for resources built into the apiserver, not ones defined by CRDs or aggregated from external servers, and is only consulted if the watch-cache is enabled. The only meaningful size setting to supply here is zero, which means to disable watch caching for the associated resource; all non-zero values are equivalent and mean to not disable watch caching for that resource |

# kube-controller-manager

## Synopsis

The Kubernetes controller manager is a daemon that embeds the core control loops shipped with Kubernetes. In applications of robotics and automation, a control loop is a non-terminating loop that regulates the state of the system. In Kubernetes, a controller is a control loop that watches the shared state of the cluster through the apiserver and makes changes attempting to move the current state towards the desired state. Examples of controllers that ship with Kubernetes today are the replication controller, endpoints controller, namespace controller, and serviceaccounts controller.

kube-controller-manager [flags]

## Options

|                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allocate-node-cidrs</code>                                                                                                                                                                                                                      |
| Should CIDRs for Pods be allocated and set on the cloud provider.                                                                                                                                                                                       |
| <code>--allow-metric-labels</code> stringToString    Default: []                                                                                                                                                                                        |
| The map from metric-label to value allow-list of this label. The key's format is <MetricName>,<LabelName>. The value's format is <allowed_value>,<allowed_value>...e.g. metric1,label1='v1,v2,v3', metric1,label2='v1,v2,v3' metric2,label1='v1,v2,v3'. |
| <code>--allow-metric-labels-manifest</code> string                                                                                                                                                                                                      |
| The path to the manifest file that contains the allow-list mapping. The format of the file is the same as the flag <code>--allow-metric-labels</code> . Note that the flag <code>--allow-metric-labels</code> will override the manifest file.          |
| <code>--attach-detach-reconcile-sync-period</code> duration    Default: 1m0s                                                                                                                                                                            |
| The reconciler sync wait time between volume attach detach. This duration must be larger than one second, and increasing this value from the default may allow for volumes to be mismatched with pods.                                                  |
| <code>--authentication-kubeconfig</code> string                                                                                                                                                                                                         |
| kubeconfig file pointing at the 'core' kubernetes server with enough rights to create tokenreviews.authentication.k8s.io. This is optional. If empty, all token requests are considered to be anonymous and no client CA is looked up in the cluster.   |
| <code>--authentication-skip-lookup</code>                                                                                                                                                                                                               |
| If false, the authentication-kubeconfig will be used to lookup missing authentication configuration from the cluster.                                                                                                                                   |
| <code>--authentication-token-webhook-cache-ttl</code> duration    Default: 10s                                                                                                                                                                          |

|                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The duration to cache responses from the webhook token authenticator.                                                                                                                                                                                                    |
| --authentication-tolerate-lookup-failure                                                                                                                                                                                                                                 |
| If true, failures to look up missing authentication configuration from the cluster are not considered fatal. Note that this can result in authentication that treats all requests as anonymous.                                                                          |
| --authorization-always-allow-paths strings    Default: "/healthz,/readyz,/livez"                                                                                                                                                                                         |
| A list of HTTP paths to skip during authorization, i.e. these are authorized without contacting the 'core' kubernetes server.                                                                                                                                            |
| --authorization-kubeconfig string                                                                                                                                                                                                                                        |
| kubeconfig file pointing at the 'core' kubernetes server with enough rights to create subjectaccessreviews.authorization.k8s.io. This is optional. If empty, all requests not skipped by authorization are forbidden.                                                    |
| --authorization-webhook-cache-authorized-ttl duration    Default: 10s                                                                                                                                                                                                    |
| The duration to cache 'authorized' responses from the webhook authorizer.                                                                                                                                                                                                |
| --authorization-webhook-cache-unauthorized-ttl duration    Default: 10s                                                                                                                                                                                                  |
| The duration to cache 'unauthorized' responses from the webhook authorizer.                                                                                                                                                                                              |
| --bind-address string    Default: 0.0.0.0                                                                                                                                                                                                                                |
| The IP address on which to listen for the --secure-port port. The associated interface(s) must be reachable by the rest of the cluster, and by CLI/web clients. If blank or an unspecified address (0.0.0.0 or ::), all interfaces and IP address families will be used. |
| --cert-dir string                                                                                                                                                                                                                                                        |
| The directory where the TLS certs are located. If --tls-cert-file and --tls-private-key-file are provided, this flag will be ignored.                                                                                                                                    |
| --cidr-allocator-type string    Default: "RangeAllocator"                                                                                                                                                                                                                |
| Type of CIDR allocator to use                                                                                                                                                                                                                                            |
| --client-ca-file string                                                                                                                                                                                                                                                  |
| If set, any request presenting a client certificate signed by one of the authorities in the client-ca-file is authenticated with an identity corresponding to the CommonName of the client certificate.                                                                  |
| --cloud-config string                                                                                                                                                                                                                                                    |

|                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The path to the cloud provider configuration file. Empty string for no configuration file.                                                                                                                    |
| --cloud-provider string                                                                                                                                                                                       |
| The provider for cloud services. Empty string for no provider.                                                                                                                                                |
| --cluster-cidr string                                                                                                                                                                                         |
| CIDR Range for Pods in cluster. Requires --allocate-node-cidrs to be true                                                                                                                                     |
| --cluster-name string    Default: "kubernetes"                                                                                                                                                                |
| The instance prefix for the cluster.                                                                                                                                                                          |
| --cluster-signing-cert-file string                                                                                                                                                                            |
| Filename containing a PEM-encoded X509 CA certificate used to issue cluster-scoped certificates. If specified, no more specific --cluster-signing-* flag may be specified.                                    |
| --cluster-signing-duration duration    Default: 8760h0m0s                                                                                                                                                     |
| The max length of duration signed certificates will be given. Individual CSRs may request shorter certs by setting spec.expirationSeconds.                                                                    |
| --cluster-signing-key-file string                                                                                                                                                                             |
| Filename containing a PEM-encoded RSA or ECDSA private key used to sign cluster-scoped certificates. If specified, no more specific --cluster-signing-* flag may be specified.                                |
| --cluster-signing-kube-apiserver-client-cert-file string                                                                                                                                                      |
| Filename containing a PEM-encoded X509 CA certificate used to issue certificates for the kubernetes.io/kube-apiserver-client signer. If specified, --cluster-signing-{cert,key}-file must not be set.         |
| --cluster-signing-kube-apiserver-client-key-file string                                                                                                                                                       |
| Filename containing a PEM-encoded RSA or ECDSA private key used to sign certificates for the kubernetes.io/kube-apiserver-client signer. If specified, --cluster-signing-{cert,key}-file must not be set.     |
| --cluster-signing-kubelet-client-cert-file string                                                                                                                                                             |
| Filename containing a PEM-encoded X509 CA certificate used to issue certificates for the kubernetes.io/kube-apiserver-client-kubelet signer. If specified, --cluster-signing-{cert,key}-file must not be set. |
| --cluster-signing-kubelet-client-key-file string                                                                                                                                                              |

|                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filename containing a PEM-encoded RSA or ECDSA private key used to sign certificates for the kubernetes.io/kube-apiserver-client-kubelet signer. If specified, --cluster-signing-{cert,key}-file must not be set. |
| --cluster-signing-kubelet-serving-cert-file string                                                                                                                                                                |
| Filename containing a PEM-encoded X509 CA certificate used to issue certificates for the kubernetes.io/kubelet-serving signer. If specified, --cluster-signing-{cert,key}-file must not be set.                   |
| --cluster-signing-kubelet-serving-key-file string                                                                                                                                                                 |
| Filename containing a PEM-encoded RSA or ECDSA private key used to sign certificates for the kubernetes.io/kubelet-serving signer. If specified, --cluster-signing-{cert,key}-file must not be set.               |
| --cluster-signing-legacy-unknown-cert-file string                                                                                                                                                                 |
| Filename containing a PEM-encoded X509 CA certificate used to issue certificates for the kubernetes.io/legacy-unknown signer. If specified, --cluster-signing-{cert,key}-file must not be set.                    |
| --cluster-signing-legacy-unknown-key-file string                                                                                                                                                                  |
| Filename containing a PEM-encoded RSA or ECDSA private key used to sign certificates for the kubernetes.io/legacy-unknown signer. If specified, --cluster-signing-{cert,key}-file must not be set.                |
| --concurrent-cron-job-syncs int32    Default: 5                                                                                                                                                                   |
| The number of cron job objects that are allowed to sync concurrently. Larger number = more responsive jobs, but more CPU (and network) load                                                                       |
| --concurrent-deployment-syncs int32    Default: 5                                                                                                                                                                 |
| The number of deployment objects that are allowed to sync concurrently. Larger number = more responsive deployments, but more CPU (and network) load                                                              |
| --concurrent-endpoint-syncs int32    Default: 5                                                                                                                                                                   |
| The number of endpoint syncing operations that will be done concurrently. Larger number = faster endpoint updating, but more CPU (and network) load                                                               |
| --concurrent-ephemeralvolume-syncs int32    Default: 5                                                                                                                                                            |
| The number of ephemeral volume syncing operations that will be done concurrently. Larger number = faster ephemeral volume updating, but more CPU (and network) load                                               |
| --concurrent-gc-syncs int32    Default: 20                                                                                                                                                                        |

|                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The number of garbage collector workers that are allowed to sync concurrently.                                                                                                                        |
| --concurrent-horizontal-pod-autoscaler-syncs int32    Default: 5                                                                                                                                      |
| The number of horizontal pod autoscaler objects that are allowed to sync concurrently. Larger number = more responsive horizontal pod autoscaler objects processing, but more CPU (and network) load. |
| --concurrent-job-syncs int32    Default: 5                                                                                                                                                            |
| The number of job objects that are allowed to sync concurrently. Larger number = more responsive jobs, but more CPU (and network) load                                                                |
| --concurrent-namespace-syncs int32    Default: 10                                                                                                                                                     |
| The number of namespace objects that are allowed to sync concurrently. Larger number = more responsive namespace termination, but more CPU (and network) load                                         |
| --concurrent-rc-syncs int32    Default: 5                                                                                                                                                             |
| The number of replication controllers that are allowed to sync concurrently. Larger number = more responsive replica management, but more CPU (and network) load                                      |
| --concurrent-replicaset-syncs int32    Default: 5                                                                                                                                                     |
| The number of replica sets that are allowed to sync concurrently. Larger number = more responsive replica management, but more CPU (and network) load                                                 |
| --concurrent-resource-quota-syncs int32    Default: 5                                                                                                                                                 |
| The number of resource quotas that are allowed to sync concurrently. Larger number = more responsive quota management, but more CPU (and network) load                                                |
| --concurrent-service-endpoint-syncs int32    Default: 5                                                                                                                                               |
| The number of service endpoint syncing operations that will be done concurrently. Larger number = faster endpoint slice updating, but more CPU (and network) load. Defaults to 5.                     |
| --concurrent-service-syncs int32    Default: 1                                                                                                                                                        |
| The number of services that are allowed to sync concurrently. Larger number = more responsive service management, but more CPU (and network) load                                                     |
| --concurrent-serviceaccount-token-syncs int32    Default: 5                                                                                                                                           |
| The number of service account token objects that are allowed to sync concurrently. Larger number = more responsive token generation, but more CPU (and network) load                                  |
| --concurrent-statefulset-syncs int32    Default: 5                                                                                                                                                    |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| --disable-attach-detach-reconcile-sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Disable volume attach detach reconciler sync. Disabling this may cause volumes to be mismatched with pods. Use wisely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--disable-force-detach-on-timeout</code>                                                                                                                                                                                                                                                                                              |
| Prevent force detaching volumes based on maximum unmount time and node status. If this flag is set to true, the non-graceful node shutdown feature must be used to recover from node failure. See <a href="https://k8s.io/docs/storage-disable-force-detach-on-timeout/">https://k8s.io/docs/storage-disable-force-detach-on-timeout/</a> . |
| <code>--disabled-metrics strings</code>                                                                                                                                                                                                                                                                                                     |
| This flag provides an escape hatch for misbehaving metrics. You must provide the fully qualified metric name in order to disable it. Disclaimer: disabling metrics is higher in precedence than showing hidden metrics.                                                                                                                     |
| <code>--enable-dynamic-provisioning</code> Default: true                                                                                                                                                                                                                                                                                    |
| Enable dynamic provisioning for environments that support it.                                                                                                                                                                                                                                                                               |
| <code>--enable-garbage-collector</code> Default: true                                                                                                                                                                                                                                                                                       |
| Enables the generic garbage collector. MUST be synced with the corresponding flag of the kube-apiserver.                                                                                                                                                                                                                                    |
| <code>--enable-hostpath-provisioner</code>                                                                                                                                                                                                                                                                                                  |
| Enable HostPath PV provisioning when running without a cloud provider. This allows testing and development of provisioning features. HostPath provisioning is not supported in any way, won't work in a multi-node cluster, and should not be used for anything other than testing or development.                                          |
| <code>--enable-leader-migration</code>                                                                                                                                                                                                                                                                                                      |
| Whether to enable controller leader migration.                                                                                                                                                                                                                                                                                              |
| <code>--endpoint-updates-batch-period duration</code>                                                                                                                                                                                                                                                                                       |
| The length of endpoint updates batching period. Processing of pod changes will be delayed by this duration to join them with potential upcoming updates and reduce the overall number of endpoints updates. Larger number = higher endpoint programming latency, but lower number of endpoints revision generated                           |
| <code>--endpointslice-updates-batch-period duration</code>                                                                                                                                                                                                                                                                                  |

| <code>--external-cloud-volume-plugin string</code>                                                                                                                                                                                                                                                                                          |

The plugin to use when cloud provider is set to external. Can be empty, should only be set when cloud-provider is external. Currently used to allow node-ipam-controller, persistentvolume-binder-controller, persistentvolume-expander-controller and attach-detach-controller to work for in tree cloud providers.

--feature-gates <comma-separated 'key=True|False' pairs>

A set of key=value pairs that describe feature gates for alpha/experimental features. Options are:

| The period after pod start during which readiness changes will be treated as initial readiness.                                                                                                                                                                                                                                                                                         |
| --horizontal-pod-autoscaler-sync-period duration    Default: 15s                                                                                                                                                                                                                                                                                                                        |
| The period for syncing the number of pods in horizontal pod autoscaler.                                                                                                                                                                                                                                                                                                                 |
| --horizontal-pod-autoscaler-tolerance float    Default: 0.1                                                                                                                                                                                                                                                                                                                             |
| The minimum change (from 1.0) in the desired-to-actual metrics ratio for the horizontal pod autoscaler to consider scaling.                                                                                                                                                                                                                                                             |
| --http2-max-streams-per-connection int                                                                                                                                                                                                                                                                                                                                                  |
| The limit that the server gives to clients for the maximum number of streams in an HTTP/2 connection. Zero means to use golang's default.                                                                                                                                                                                                                                               |
| --kube-api-burst int32    Default: 30                                                                                                                                                                                                                                                                                                                                                   |
| Burst to use while talking with kubernetes apiserver.                                                                                                                                                                                                                                                                                                                                   |
| --kube-api-content-type string    Default: "application/vnd.kubernetes.protobuf"                                                                                                                                                                                                                                                                                                        |
| Content type of requests sent to apiserver.                                                                                                                                                                                                                                                                                                                                             |
| --kube-api-qps float    Default: 20                                                                                                                                                                                                                                                                                                                                                     |
| QPS to use while talking with kubernetes apiserver.                                                                                                                                                                                                                                                                                                                                     |
| --kubeconfig string                                                                                                                                                                                                                                                                                                                                                                     |
| Path to kubeconfig file with authorization and master location information (the master location can be overridden by the master flag).                                                                                                                                                                                                                                                  |
| --large-cluster-size-threshold int32    Default: 50                                                                                                                                                                                                                                                                                                                                     |
| Number of nodes from which node-lifecycle-controller treats the cluster as large for the eviction logic purposes. --secondary-node-eviction-rate is implicitly overridden to 0 for clusters this size or smaller. Notice: If nodes reside in multiple zones, this threshold will be considered as zone node size threshold for each zone to determine node eviction rate independently. |
| --leader-elect    Default: true                                                                                                                                                                                                                                                                                                                                                         |
| Start a leader election client and gain leadership before executing the main loop. Enable this when running replicated components for high availability.                                                                                                                                                                                                                                |

|                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--leader-elect-lease-duration</code> duration    Default: 15s                                                                                                                                                                                                                                                                        |
| The duration that non-leader candidates will wait after observing a leadership renewal until attempting to acquire leadership of a led but unrenewed leader slot. This is effectively the maximum duration that a leader can be stopped before it is replaced by another candidate. This is only applicable if leader election is enabled. |
| <code>--leader-elect-renew-deadline</code> duration    Default: 10s                                                                                                                                                                                                                                                                        |
| The interval between attempts by the acting master to renew a leadership slot before it stops leading. This must be less than the lease duration. This is only applicable if leader election is enabled.                                                                                                                                   |
| <code>--leader-elect-resource-lock</code> string    Default: "leases"                                                                                                                                                                                                                                                                      |
| The type of resource object that is used for locking during leader election. Supported options are 'leases', 'endpointsleases' and 'configmapsleases'.                                                                                                                                                                                     |
| <code>--leader-elect-resource-name</code> string    Default: "kube-controller-manager"                                                                                                                                                                                                                                                     |
| The name of resource object that is used for locking during leader election.                                                                                                                                                                                                                                                               |
| <code>--leader-elect-resource-namespace</code> string    Default: "kube-system"                                                                                                                                                                                                                                                            |
| The namespace of resource object that is used for locking during leader election.                                                                                                                                                                                                                                                          |
| <code>--leader-elect-retry-period</code> duration    Default: 2s                                                                                                                                                                                                                                                                           |
| The duration the clients should wait between attempting acquisition and renewal of a leadership. This is only applicable if leader election is enabled.                                                                                                                                                                                    |
| <code>--leader-migration-config</code> string                                                                                                                                                                                                                                                                                              |
| Path to the config file for controller leader migration, or empty to use the value that reflects default configuration of the controller manager. The config file should be of type LeaderMigrationConfiguration, group controllermanager.config.k8s.io, version v1alpha1.                                                                 |
| <code>--legacy-service-account-token-clean-up-period</code> duration    Default: 8760h0m0s                                                                                                                                                                                                                                                 |
| The period of time since the last usage of an legacy service account token before it can be deleted.                                                                                                                                                                                                                                       |
| <code>--log-flush-frequency</code> duration    Default: 5s                                                                                                                                                                                                                                                                                 |
| Maximum number of seconds between log flushes                                                                                                                                                                                                                                                                                              |
| <code>--log-text-info-buffer-size</code> quantity                                                                                                                                                                                                                                                                                          |

|                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>[Alpha] In text format with split output streams, the info messages can be buffered for a while to increase performance. The default value of zero bytes disables buffering. The size can be specified as number of bytes (512), multiples of 1000 (1K), multiples of 1024 (2Ki), or powers of those (3M, 4G, 5Mi, 6Gi). Enable the LoggingAlphaOptions feature gate to use this.</p> |
| <p>--log-text-split-stream</p>                                                                                                                                                                                                                                                                                                                                                           |
| <p>[Alpha] In text format, write error messages to stderr and info messages to stdout. The default is to write a single stream to stdout. Enable the LoggingAlphaOptions feature gate to use this.</p>                                                                                                                                                                                   |
| <p>--logging-format string    Default: "text"</p>                                                                                                                                                                                                                                                                                                                                        |
| <p>Sets the log format. Permitted formats: "text".</p>                                                                                                                                                                                                                                                                                                                                   |

| <p>The address of the Kubernetes API server (overrides any value in kubeconfig).</p>                                                                                                                                                                                                                                                                                                     |
| <p>--max-endpoints-per-slice int32    Default: 100</p>                                                                                                                                                                                                                                                                                                                                   |
| <p>The maximum number of endpoints that will be added to an EndpointSlice. More endpoints per slice will result in less endpoint slices, but larger resources. Defaults to 100.</p>                                                                                                                                                                                                      |
| <p>--min-resync-period duration    Default: 12h0m0s</p>                                                                                                                                                                                                                                                                                                                                  |
| <p>The resync period in reflectors will be random between MinResyncPeriod and 2*MinResyncPeriod.</p>                                                                                                                                                                                                                                                                                     |
| <p>--mirroring-concurrent-service-endpoint-syncs int32    Default: 5</p>                                                                                                                                                                                                                                                                                                                 |
| <p>The number of service endpoint syncing operations that will be done concurrently by the endpointslice-mirroring-controller. Larger number = faster endpoint slice updating, but more CPU (and network) load. Defaults to 5.</p>                                                                                                                                                       |
| <p>--mirroring-endpointslice-updates-batch-period duration</p>                                                                                                                                                                                                                                                                                                                           |
| <p>The length of EndpointSlice updates batching period for endpointslice-mirroring-controller. Processing of EndpointSlice changes will be delayed by this duration to join them with potential upcoming updates and reduce the overall number of EndpointSlice updates. Larger number = higher endpoint programming latency, but lower number of endpoints revision generated</p>       |
| <p>--mirroring-max-endpoints-per-subset int32    Default: 1000</p>                                                                                                                                                                                                                                                                                                                       |
| <p>The maximum number of endpoints that will be added to an EndpointSlice by the endpointslice-mirroring-controller. More endpoints per slice will result in less endpoint slices, but larger resources. Defaults to 100.</p>                                                                                                                                                            |
| <p>--namespace-sync-period duration    Default: 5m0s</p>                                                                                                                                                                                                                                                                                                                                 |

|                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The period for syncing namespace life-cycle updates                                                                                                                                                                                  |
| --node-cidr-mask-size int32                                                                                                                                                                                                          |
| Mask size for node cidr in cluster. Default is 24 for IPv4 and 64 for IPv6.                                                                                                                                                          |
| --node-cidr-mask-size-ipv4 int32                                                                                                                                                                                                     |
| Mask size for IPv4 node cidr in dual-stack cluster. Default is 24.                                                                                                                                                                   |
| --node-cidr-mask-size-ipv6 int32                                                                                                                                                                                                     |
| Mask size for IPv6 node cidr in dual-stack cluster. Default is 64.                                                                                                                                                                   |
| --node-eviction-rate float    Default: 0.1                                                                                                                                                                                           |
| Number of nodes per second on which pods are deleted in case of node failure when a zone is healthy (see --unhealthy-zone-threshold for definition of healthy/unhealthy). Zone refers to entire cluster in non-multizone clusters.   |
| --node-monitor-grace-period duration    Default: 40s                                                                                                                                                                                 |
| Amount of time which we allow running Node to be unresponsive before marking it unhealthy. Must be N times more than kubelet's nodeStatusUpdateFrequency, where N means number of retries allowed for kubelet to post node status.   |
| --node-monitor-period duration    Default: 5s                                                                                                                                                                                        |
| The period for syncing NodeStatus in cloud-node-lifecycle-controller.                                                                                                                                                                |
| --node-startup-grace-period duration    Default: 1m0s                                                                                                                                                                                |
| Amount of time which we allow starting Node to be unresponsive before marking it unhealthy.                                                                                                                                          |
| --permit-address-sharing                                                                                                                                                                                                             |
| If true, SO_REUSEADDR will be used when binding the port. This allows binding to wildcard IPs like 0.0.0.0 and specific IPs in parallel, and it avoids waiting for the kernel to release sockets in TIME_WAIT state. [default=false] |
| --permit-port-sharing                                                                                                                                                                                                                |
| If true, SO_REUSEPORT will be used when binding the port, which allows more than one instance to bind on the same address and port. [default=false]                                                                                  |
| --profiling    Default: true                                                                                                                                                                                                         |
| Enable profiling via web interface host:port/debug/pprof/                                                                                                                                                                            |
| --pv-recycler-increment-timeout-nfs int32    Default: 30                                                                                                                                                                             |

|                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| the increment of time added per Gi to ActiveDeadlineSeconds for an NFS scrubber pod                                                                                                                                                                               |
| --pv-recycler-minimum-timeout-hostpath int32    Default: 60                                                                                                                                                                                                       |
| The minimum ActiveDeadlineSeconds to use for a HostPath Recycler pod. This is for development and testing only and will not work in a multi-node cluster.                                                                                                         |
| --pv-recycler-minimum-timeout-nfs int32    Default: 300                                                                                                                                                                                                           |
| The minimum ActiveDeadlineSeconds to use for an NFS Recycler pod                                                                                                                                                                                                  |
| --pv-recycler-pod-template-filepath-hostpath string                                                                                                                                                                                                               |
| The file path to a pod definition used as a template for HostPath persistent volume recycling. This is for development and testing only and will not work in a multi-node cluster.                                                                                |
| --pv-recycler-pod-template-filepath-nfs string                                                                                                                                                                                                                    |
| The file path to a pod definition used as a template for NFS persistent volume recycling                                                                                                                                                                          |
| --pv-recycler-timeout-increment-hostpath int32    Default: 30                                                                                                                                                                                                     |
| the increment of time added per Gi to ActiveDeadlineSeconds for a HostPath scrubber pod. This is for development and testing only and will not work in a multi-node cluster.                                                                                      |
| --pvclaimbinder-sync-period duration    Default: 15s                                                                                                                                                                                                              |
| The period for syncing persistent volumes and persistent volume claims                                                                                                                                                                                            |
| --requestheader-allowed-names strings                                                                                                                                                                                                                             |
| List of client certificate common names to allow to provide usernames in headers specified by --requestheader-username-headers. If empty, any client certificate validated by the authorities in --requestheader-client-ca-file is allowed.                       |

| List of request headers to inspect for usernames. X-Remote-User is common.                                                                                                                                                                                                                                                                                                                                      |
| --resource-quota-sync-period duration    Default: 5m0s                                                                                                                                                                                                                                                                                                                                                          |
| The period for syncing quota usage status in the system                                                                                                                                                                                                                                                                                                                                                         |
| --root-ca-file string                                                                                                                                                                                                                                                                                                                                                                                           |
| If set, this root certificate authority will be included in service account's token secret. This must be a valid PEM-encoded CA bundle.                                                                                                                                                                                                                                                                         |
| --route-reconciliation-period duration    Default: 10s                                                                                                                                                                                                                                                                                                                                                          |
| The period for reconciling routes created for Nodes by cloud provider.                                                                                                                                                                                                                                                                                                                                          |
| --secondary-node-eviction-rate float    Default: 0.01                                                                                                                                                                                                                                                                                                                                                           |
| Number of nodes per second on which pods are deleted in case of node failure when a zone is unhealthy (see --unhealthy-zone-threshold for definition of healthy/unhealthy). Zone refers to entire cluster in non-multizone clusters. This value is implicitly overridden to 0 if the cluster size is smaller than --large-cluster-size-threshold.                                                               |
| --secure-port int    Default: 10257                                                                                                                                                                                                                                                                                                                                                                             |
| The port on which to serve HTTPS with authentication and authorization. If 0, don't serve HTTPS at all.                                                                                                                                                                                                                                                                                                         |
| --service-account-private-key-file string                                                                                                                                                                                                                                                                                                                                                                       |
| Filename containing a PEM-encoded private RSA or ECDSA key used to sign service account tokens.                                                                                                                                                                                                                                                                                                                 |
| --service-cluster-ip-range string                                                                                                                                                                                                                                                                                                                                                                               |
| CIDR Range for Services in cluster. Requires --allocate-node-cidrs to be true                                                                                                                                                                                                                                                                                                                                   |
| --show-hidden-metrics-for-version string                                                                                                                                                                                                                                                                                                                                                                        |
| The previous version for which you want to show hidden metrics. Only the previous minor version is meaningful, other values will not be allowed. The format is <major>.<minor>, e.g.: '1.16'. The purpose of this format is make sure you have the opportunity to notice if the next release hides additional metrics, rather than being surprised when they are permanently removed in the release after that. |
| --terminated-pod-gc-threshold int32    Default: 12500                                                                                                                                                                                                                                                                                                                                                           |
| Number of terminated pods that can exist before the terminated pod garbage collector starts deleting terminated pods. If <= 0, the terminated pod garbage collector is disabled.                                                                                                                                                                                                                                |

# kube-proxy

## Synopsis

The Kubernetes network proxy runs on each node. This reflects services as defined in the Kubernetes API on each node and can do simple TCP, UDP, and SCTP stream forwarding or round robin TCP, UDP, and SCTP forwarding across a set of backends. Service cluster IPs and ports are currently found through Docker-links-compatible environment variables specifying ports opened by the service proxy. There is an optional addon that provides cluster DNS for these cluster IPs. The user must create a service with the apiserver API to configure the proxy.

kube-proxy [flags]

| <code>--add_dir_header</code>                                                           |                  |
| If true, adds the file directory to the header of the log messages                      |                  |
| <code>--alsologtostderr</code>                                                          |                  |
| log to standard error as well as files (no effect when <code>-logtostderr=true</code> ) |                  |
| <code>--bind-address string</code>                                                      | Default: 0.0.0.0 |

|                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Overrides kube-proxy's idea of what its node's primary IP is. Note that the name is a historical artifact, and kube-proxy does not actually bind any sockets to this IP. This parameter is ignored if a config file is specified by --config.                                                                                                                         |
| --bind-address-hard-fail                                                                                                                                                                                                                                                                                                                                              |
| If true kube-proxy will treat failure to bind to a port as fatal and exit                                                                                                                                                                                                                                                                                             |
| --cleanup                                                                                                                                                                                                                                                                                                                                                             |
| If true cleanup iptables and ipvs rules and exit.                                                                                                                                                                                                                                                                                                                     |
| --cluster-cidr string                                                                                                                                                                                                                                                                                                                                                 |
| The CIDR range of the pods in the cluster. (For dual-stack clusters, this can be a comma-separated dual-stack pair of CIDR ranges.). When --detect-local-mode is set to ClusterCIDR, kube-proxy will consider traffic to be local if its source IP is in this range. (Otherwise it is not used.) This parameter is ignored if a config file is specified by --config. |
| --config string                                                                                                                                                                                                                                                                                                                                                       |
| The path to the configuration file.                                                                                                                                                                                                                                                                                                                                   |
| --config-sync-period duration    Default: 15m0s                                                                                                                                                                                                                                                                                                                       |
| How often configuration from the apiserver is refreshed. Must be greater than 0.                                                                                                                                                                                                                                                                                      |
| --conntrack-max-per-core int32    Default: 32768                                                                                                                                                                                                                                                                                                                      |
| Maximum number of NAT connections to track per CPU core (0 to leave the limit as-is and ignore conntrack-min).                                                                                                                                                                                                                                                        |
| --conntrack-min int32    Default: 131072                                                                                                                                                                                                                                                                                                                              |
| Minimum number of conntrack entries to allocate, regardless of conntrack-max-per-core (set conntrack-max-per-core=0 to leave the limit as-is).                                                                                                                                                                                                                        |
| --conntrack-tcp-be-liberal                                                                                                                                                                                                                                                                                                                                            |
| Enable liberal mode for tracking TCP packets by setting nf_conntrack_tcp_be_liberal to 1                                                                                                                                                                                                                                                                              |

|                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If non-empty, will be used as the name of the Node that kube-proxy is running on. If unset, the node name is assumed to be the same as the node's hostname.                                                                            |
| --init-only                                                                                                                                                                                                                            |
| If true, perform any initialization steps that must be done with full root privileges, and then exit. After doing this, you can run kube-proxy again with only the CAP_NET_ADMIN capability.                                           |
| --iptables-localhost-nodeports    Default: true                                                                                                                                                                                        |
| If false, kube-proxy will disable the legacy behavior of allowing NodePort services to be accessed via localhost. (Applies only to iptables mode and IPv4; localhost NodePorts are never allowed with other proxy modes or with IPv6.) |
| --iptables-masquerade-bit int32    Default: 14                                                                                                                                                                                         |
| If using the iptables or ipvs proxy mode, the bit of the fwmark space to mark packets requiring SNAT with. Must be within the range [0, 31].                                                                                           |
| --iptables-min-sync-period duration    Default: 1s                                                                                                                                                                                     |
| The minimum period between iptables rule resyncs (e.g. '5s', '1m', '2h22m'). A value of 0 means every Service or EndpointSlice change will result in an immediate iptables resync.                                                     |
| --iptables-sync-period duration    Default: 30s                                                                                                                                                                                        |
| An interval (e.g. '5s', '1m', '2h22m') indicating how frequently various re-synchronizing and cleanup operations are performed. Must be greater than 0.                                                                                |
| --ipvs-exclude-cidrs strings                                                                                                                                                                                                           |
| A comma-separated list of CIDRs which the ipvs proxier should not touch when cleaning up IPVS rules.                                                                                                                                   |
| --ipvs-min-sync-period duration                                                                                                                                                                                                        |
| The minimum period between IPVS rule resyncs (e.g. '5s', '1m', '2h22m'). A value of 0 means every Service or EndpointSlice change will result in an immediate IPVS resync.                                                             |
| --ipvs-scheduler string                                                                                                                                                                                                                |
| The ipvs scheduler type when proxy mode is ipvs                                                                                                                                                                                        |
| --ipvs-strict-arp                                                                                                                                                                                                                      |
| Enable strict ARP by setting arp_ignore to 1 and arp_announce to 2                                                                                                                                                                     |
| --ipvs-sync-period duration    Default: 30s                                                                                                                                                                                            |

|                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An interval (e.g. '5s', '1m', '2h22m') indicating how frequently various re-synchronizing and cleanup operations are performed. Must be greater than 0.                                                                                                                                                                                                                           |

| [Alpha] In text format with split output streams, the info messages can be buffered for a while to increase performance. The default value of zero bytes disables buffering. The size can be specified as number of bytes (512), multiples of 1000 (1K), multiples of 1024 (2Ki), or powers of those (3M, 4G, 5Mi, 6Gi). Enable the LoggingAlphaOptions feature gate to use this. |
| <code>--log-text-split-stream</code>                                                                                                                                                                                                                                                                                                                                              |
| [Alpha] In text format, write error messages to stderr and info messages to stdout. The default is to write a single stream to stdout. Enable the LoggingAlphaOptions feature gate to use this.                                                                                                                                                                                   |

| If using the iptables or ipvs proxy mode, SNAT all traffic sent via Service cluster IPs. This may be required with some CNI plugins.                                                                                                                                                                                                          |
| --master string                                                                                                                                                                                                                                                                                                                               |
| The address of the Kubernetes API server (overrides any value in kubeconfig)                                                                                                                                                                                                                                                                  |
| --metrics-bind-address ipport   Default: 127.0.0.1:10249                                                                                                                                                                                                                                                                                      |
| The IP address and port for the metrics server to serve on, defaulting to "127.0.0.1:10249" (if --bind-address is unset or IPv4), or "[::1]:10249" (if --bind-address is IPv6). (Set to "0.0.0.0:10249" / "[::]:10249" to bind on all interfaces.) Set empty to disable. This parameter is ignored if a config file is specified by --config. |
| --nodeport-addresses strings                                                                                                                                                                                                                                                                                                                  |
| A list of CIDR ranges that contain valid node IPs. If set, connections to NodePort services will only be accepted on node IPs in one of the indicated ranges. If unset, NodePort connections will be accepted on all local IPs. This parameter is ignored if a config file is specified by --config.                                          |
| --one_output                                                                                                                                                                                                                                                                                                                                  |
| If true, only write logs to their native severity level (vs also writing to each lower severity level; no effect when -logtostderr=true)                                                                                                                                                                                                      |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--oom-score-adj int32</code> Default: -999                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| The oom-score-adj value for kube-proxy process. Values must be within the range [-1000, 1000]. This parameter is ignored if a config file is specified by <code>--config</code> .                                                                                                                                                                                                                                                                                                                  |
| <code>--pod-bridge-interface string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| A bridge interface name. When <code>--detect-local-mode</code> is set to <code>BridgeInterface</code> , kube-proxy will consider traffic to be local if it originates from this bridge.                                                                                                                                                                                                                                                                                                            |
| <code>--pod-interface-name-prefix string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| An interface name prefix. When <code>--detect-local-mode</code> is set to <code>InterfaceNamePrefix</code> , kube-proxy will consider traffic to be local if it originates from any interface whose name begins with this prefix.                                                                                                                                                                                                                                                                  |
| <code>--profiling</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| If true enables profiling via web interface on <code>/debug/pprof</code> handler. This parameter is ignored if a config file is specified by <code>--config</code> .                                                                                                                                                                                                                                                                                                                               |
| <code>--proxy-mode ProxyMode</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Which proxy mode to use: on Linux this can be 'iptables' (default) or 'ipvs'. On Windows the only supported value is 'kernel-space'. This parameter is ignored if a config file is specified by <code>--config</code> .                                                                                                                                                                                                                                                                            |
| <code>--show-hidden-metrics-for-version string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| The previous version for which you want to show hidden metrics. Only the previous minor version is meaningful, other values will not be allowed. The format is <major>.<minor>, e.g.: '1.16'. The purpose of this format is make sure you have the opportunity to notice if the next release hides additional metrics, rather than being surprised when they are permanently removed in the release after that. This parameter is ignored if a config file is specified by <code>--config</code> . |
| <code>--skip_headers</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| If true, avoid header prefixes in the log messages                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>--skip_log_headers</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| If true, avoid headers when opening log files (no effect when <code>-logtostderr=true</code> )                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>--stderrthreshold int</code> Default: 2                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| logs at or above this threshold go to stderr when writing to files and stderr (no effect when <code>-logtostderr=true</code> or <code>-alsologtostderr=true</code> )                                                                                                                                                                                                                                                                                                                               |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| number for the log level verbosity                                                                           |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --vmodule pattern=N,...                                                                                      |
| comma-separated list of pattern=N settings for file-filtered logging (only works for text log format)        |
| --write-config-to string                                                                                     |
| If set, write the default configuration values to this file and exit.                                        |

# kube-scheduler

## Synopsis

The Kubernetes scheduler is a control plane process which assigns Pods to Nodes. The scheduler determines which Nodes are valid placements for each Pod in the scheduling queue according to constraints and available resources. The scheduler then ranks each valid Node and binds the Pod to a suitable Node. Multiple different schedulers may be used within a cluster; kube-scheduler is the reference implementation. See [scheduling](#) for more information about scheduling and the kube-scheduler component.

kube-scheduler [flags]

## Options

|                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-metric-labels stringToString    Default: []                                                                                                                                                                                                     |
| The map from metric-label to value allow-list of this label. The key's format is <MetricName>,<LabelName>. The value's format is <allowed_value>,<allowed_value>...e.g. metric1,label1='v1,v2,v3', metric1,label2='v1,v2,v3' metric2,label1='v1,v2,v3'. |
| --allow-metric-labels-manifest string                                                                                                                                                                                                                   |
| The path to the manifest file that contains the allow-list mapping. The format of the file is the same as the flag --allow-metric-labels. Note that the flag --allow-metric-labels will override the manifest file.                                     |
| --authentication-kubeconfig string                                                                                                                                                                                                                      |

|                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kubeconfig file pointing at the 'core' kubernetes server with enough rights to create tokenreviews.authentication.k8s.io. This is optional. If empty, all token requests are considered to be anonymous and no client CA is looked up in the cluster.                    |
| --authentication-skip-lookup                                                                                                                                                                                                                                             |
| If false, the authentication-kubeconfig will be used to lookup missing authentication configuration from the cluster.                                                                                                                                                    |
| --authentication-token-webhook-cache-ttl duration    Default: 10s                                                                                                                                                                                                        |
| The duration to cache responses from the webhook token authenticator.                                                                                                                                                                                                    |
| --authentication-tolerate-lookup-failure    Default: true                                                                                                                                                                                                                |
| If true, failures to look up missing authentication configuration from the cluster are not considered fatal. Note that this can result in authentication that treats all requests as anonymous.                                                                          |
| --authorization-always-allow-paths strings    Default: "/healthz,/readyz,/livez"                                                                                                                                                                                         |
| A list of HTTP paths to skip during authorization, i.e. these are authorized without contacting the 'core' kubernetes server.                                                                                                                                            |
| --authorization-kubeconfig string                                                                                                                                                                                                                                        |
| kubeconfig file pointing at the 'core' kubernetes server with enough rights to create subjectaccessreviews.authorization.k8s.io. This is optional. If empty, all requests not skipped by authorization are forbidden.                                                    |
| --authorization-webhook-cache-authorized-ttl duration    Default: 10s                                                                                                                                                                                                    |
| The duration to cache 'authorized' responses from the webhook authorizer.                                                                                                                                                                                                |
| --authorization-webhook-cache-unauthorized-ttl duration    Default: 10s                                                                                                                                                                                                  |
| The duration to cache 'unauthorized' responses from the webhook authorizer.                                                                                                                                                                                              |
| --bind-address string    Default: 0.0.0.0                                                                                                                                                                                                                                |
| The IP address on which to listen for the --secure-port port. The associated interface(s) must be reachable by the rest of the cluster, and by CLI/web clients. If blank or an unspecified address (0.0.0.0 or ::), all interfaces and IP address families will be used. |
| --cert-dir string                                                                                                                                                                                                                                                        |
| The directory where the TLS certs are located. If --tls-cert-file and --tls-private-key-file are provided, this flag will be ignored.                                                                                                                                    |
| --client-ca-file string                                                                                                                                                                                                                                                  |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| This flag provides an escape hatch for misbehaving metrics. You must provide the fully qualified metric name in order to disable it. Disclaimer: disabling metrics is higher in precedence than showing hidden metrics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| --kube-api-content-type string    Default: "application/vnd.kubernetes.protobuf"                                                                                                                                                                                                                                                           |
| DEPRECATED: content type of requests sent to apiserver. This parameter is ignored if a config file is specified in --config.                                                                                                                                                                                                               |
| --kube-api-qps float    Default: 50                                                                                                                                                                                                                                                                                                        |
| DEPRECATED: QPS to use while talking with kubernetes apiserver. This parameter is ignored if a config file is specified in --config.                                                                                                                                                                                                       |
| --kubeconfig string                                                                                                                                                                                                                                                                                                                        |
| DEPRECATED: path to kubeconfig file with authorization and master location information. This parameter is ignored if a config file is specified in --config.                                                                                                                                                                               |
| --leader-elect    Default: true                                                                                                                                                                                                                                                                                                            |
| Start a leader election client and gain leadership before executing the main loop. Enable this when running replicated components for high availability.                                                                                                                                                                                   |
| --leader-elect-lease-duration duration    Default: 15s                                                                                                                                                                                                                                                                                     |
| The duration that non-leader candidates will wait after observing a leadership renewal until attempting to acquire leadership of a led but unrenewed leader slot. This is effectively the maximum duration that a leader can be stopped before it is replaced by another candidate. This is only applicable if leader election is enabled. |
| --leader-elect-renew-deadline duration    Default: 10s                                                                                                                                                                                                                                                                                     |
| The interval between attempts by the acting master to renew a leadership slot before it stops leading. This must be less than the lease duration. This is only applicable if leader election is enabled.                                                                                                                                   |
| --leader-elect-resource-lock string    Default: "leases"                                                                                                                                                                                                                                                                                   |
| The type of resource object that is used for locking during leader election. Supported options are 'leases', 'endpointsleases' and 'configmapsleases'.                                                                                                                                                                                     |
| --leader-elect-resource-name string    Default: "kube-scheduler"                                                                                                                                                                                                                                                                           |

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                   | The name of resource object that is used for locking during leader election.                                                                                                                                                                                                                                                                                                      |
| --leader-elect-resource-namespace string          | Default: "kube-system"                                                                                                                                                                                                                                                                                                                                                            |
|                                                   | The namespace of resource object that is used for locking during leader election.                                                                                                                                                                                                                                                                                                 |
| --leader-elect-retry-period duration              | Default: 2s                                                                                                                                                                                                                                                                                                                                                                       |
|                                                   | The duration the clients should wait between attempting acquisition and renewal of a leadership. This is only applicable if leader election is enabled.                                                                                                                                                                                                                           |
| --log-flush-frequency duration                    | Default: 5s                                                                                                                                                                                                                                                                                                                                                                       |
|                                                   | Maximum number of seconds between log flushes                                                                                                                                                                                                                                                                                                                                     |
| --log-text-info-buffer-size quantity              |                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                   | [Alpha] In text format with split output streams, the info messages can be buffered for a while to increase performance. The default value of zero bytes disables buffering. The size can be specified as number of bytes (512), multiples of 1000 (1K), multiples of 1024 (2Ki), or powers of those (3M, 4G, 5Mi, 6Gi). Enable the LoggingAlphaOptions feature gate to use this. |
| --log-text-split-stream                           |                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                   | [Alpha] In text format, write error messages to stderr and info messages to stdout. The default is to write a single stream to stdout. Enable the LoggingAlphaOptions feature gate to use this.                                                                                                                                                                                   |
| --logging-format string                           | Default: "text"                                                                                                                                                                                                                                                                                                                                                                   |

| --requestheader-username-headers strings    Default: "x-remote-user"                                                                                                                                                                                                                                                                                                                                            |
| List of request headers to inspect for usernames. X-Remote-User is common.                                                                                                                                                                                                                                                                                                                                      |
| --secure-port int    Default: 10259                                                                                                                                                                                                                                                                                                                                                                             |
| The port on which to serve HTTPS with authentication and authorization. If 0, don't serve HTTPS at all.                                                                                                                                                                                                                                                                                                         |
| --show-hidden-metrics-for-version string                                                                                                                                                                                                                                                                                                                                                                        |
| The previous version for which you want to show hidden metrics. Only the previous minor version is meaningful, other values will not be allowed. The format is <major>.<minor>, e.g.: '1.16'. The purpose of this format is make sure you have the opportunity to notice if the next release hides additional metrics, rather than being surprised when they are permanently removed in the release after that. |
| --tls-cert-file string                                                                                                                                                                                                                                                                                                                                                                                          |
| File containing the default x509 Certificate for HTTPS. (CA cert, if any, concatenated after server cert). If HTTPS serving is enabled, and --tls-cert-file and --tls-private-key-file are not                                                                                                                                                                                                                  |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| --tls-sni-cert-key string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <p>A pair of x509 certificate and private key file paths, optionally suffixed with a list of domain patterns which are fully qualified domain names, possibly with prefixed wildcard segments. The domain patterns also allow IP addresses, but IPs should only be used if the apiserver has visibility to the IP address requested by a client. If no domain patterns are provided, the names of the certificate are extracted. Non-wildcard matches trump over wildcard matches, explicit domain patterns trump over extracted names. For multiple key/certificate pairs, use the --tls-sni-cert-key multiple times. Examples: "example.crt,example.key" or "foo.crt,foo.key:*.foo.com,foo.com".</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Debug cluster

---

### [Flow control](#)

## Flow control

API Priority and Fairness controls the behavior of the Kubernetes API server in an overload situation. You can find more information about it in the [API Priority and Fairness](#) documentation.

## Diagnostics

Every HTTP response from an API server with the priority and fairness feature enabled has two extra headers: X-Kubernetes-PF-FlowSchema-UID and X-Kubernetes-PF-PriorityLevel-UID, noting the flow schema that matched the request and the priority level to which it was assigned, respectively. The API objects' names are not included in these headers (to avoid revealing details in case the requesting user does not have permission to view them). When debugging, you can use a command such as:

```
kubectl get flowschemas -o custom-columns="uid:{metadata.uid},name:{metadata.name}"
kubectl get prioritylevelconfigurations -o custom-columns="uid:{metadata.uid},name:{metadata.name}"
```

to get a mapping of UIDs to names for both FlowSchemas and PriorityLevelConfigurations.

## Debug endpoints

With the `APIPriorityAndFairness` feature enabled, the `kube-apiserver` serves the following additional paths at its HTTP(S) ports.

You need to ensure you have permissions to access these endpoints. You don't have to do anything if you are using admin. Permissions can be granted if needed following the [RBAC](#) doc to access `/debug/api_priority_and_fairness/` by specifying `nonResourceURLs`.

- `/debug/api_priority_and_fairness/dump_priority_levels` - a listing of all the priority levels and the current state of each. You can fetch like this:

```
kubectl get --raw /debug/api_priority_and_fairness/dump_priority_levels
```

The output will be in CSV and similar to this:

```
PriorityLevelName, ActiveQueues, IsIdle, IsQuiescing, WaitingRequests,
ExecutingRequests, DispatchedRequests, RejectedRequests, TimedoutRequests,
CancelledRequests
catch-all, 0, true, false, 0, 0, 1, 0,
0, 0
exempt, 0, true, false, 0, 0, 0, 0,
0, 0
global-default, 0, true, false, 0, 0, 46, 0,
0, 0
leader-election, 0, true, false, 0, 0, 4, 0,
0, 0
node-high, 0, true, false, 0, 0, 34, 0,
0, 0
system, 0, true, false, 0, 0, 48, 0,
0, 0
workload-high, 0, true, false, 0, 0, 500,
0, 0, 0
workload-low, 0, true, false, 0, 0, 0, 0,
0, 0
```

Explanation for selected column names:

- `IsQuiescing` indicates if this priority level will be removed when its queues have been drained.

- `/debug/api_priority_and_fairness/dump_queues` - a listing of all the queues and their current state. You can fetch like this:

```
kubectl get --raw /debug/api_priority_and_fairness/dump_queues
```

The output will be in CSV and similar to this:

```
PriorityLevelName, Index, PendingRequests, ExecutingRequests, SeatsInUse,
NextDispatchR, InitialSeatsSum, MaxSeatsSum, TotalWorkSum
workload-low, 14, 27, 0, 0, 77.64342019ss, 270,
270, 0.81000000ss
workload-low, 74, 26, 0, 0, 76.95387841ss, 260,
260, 0.78000000ss
...
leader-election, 0, 0, 0, 0, 5088.87053833ss, 0, 0,
0.00000000ss
leader-election, 1, 0, 0, 0, 0.00000000ss, 0, 0,
0.00000000ss
```

```
...
workload-high, 0, 0, 0, 0, 0.00000000ss, 0, 0,
0.00000000ss
workload-high, 1, 0, 0, 0, 1119.44936475ss, 0,
0, 0.00000000ss
```

Explanation for selected column names:

- NextDispatchR: The R progress meter reading, in units of seat-seconds, at which the next request will be dispatched.
- InitialSeatsSum: The sum of InitialSeats associated with all requests in a given queue.
- MaxSeatsSum: The sum of MaxSeats associated with all requests in a given queue.
- TotalWorkSum: The sum of total work, in units of seat-seconds, of all waiting requests in a given queue.

Note: seat-second (abbreviate as ss) is a measure of work, in units of seat-seconds, in the APF world.

- `/debug/api_priority_and_fairness/dump_requests` - a listing of all the requests including requests waiting in a queue and requests being executing. You can fetch like this:

```
kubectl get --raw /debug/api_priority_and_fairness/dump_requests
```

The output will be in CSV and similar to this:

```
PriorityLevelName, FlowSchemaName, QueueIndex, RequestIndexInQueue,
FlowDistinguisher, ArriveTime, InitialSeats, FinalSeats,
AdditionalLatency, StartTime
exempt, exempt, -1, -1, ,
2023-07-15T04:51:25.596404345Z, 1, 0, 0s,
2023-07-15T04:51:25.596404345Z
workload-low, service-accounts, 14, 0,
system:serviceaccount:default:loadtest, 2023-07-18T00:12:51.386556253Z, 10, 0,
0s, 0001-01-01T00:00:00Z
workload-low, service-accounts, 14, 1,
system:serviceaccount:default:loadtest, 2023-07-18T00:12:51.487092539Z, 10, 0,
0s, 0001-01-01T00:00:00Z
```

You can get a more detailed listing with a command like this:

```
kubectl get --raw '/debug/api_priority_and_fairness/dump_requests?
includeRequestDetails=1'
```

The output will be in CSV and similar to this:

```
PriorityLevelName, FlowSchemaName, QueueIndex, RequestIndexInQueue,
FlowDistinguisher, ArriveTime, InitialSeats, FinalSeats,
AdditionalLatency, StartTime, Username, Verb,
APIPath, Namespace, Name, APIVersion, Resource, SubResource
exempt, exempt, -1, -1, ,
2023-07-15T04:51:25.596404345Z, 1, 0, 0s,
2023-07-15T04:51:25.596404345Z, system:serviceaccount:system:admin, list, /api/v1/
namespaces/kube-stress/configmaps, kube-stress, , v1, configmaps,
```

```
workload-low, service-accounts, 14, 0,
system:serviceaccount:default:loadtest, 2023-07-18T00:13:08.986534842Z, 10, 0,

api/v1/namespaces/kube-stress/configmaps, kube-stress, , v1, configmaps,
```

Explanation for selected column names:

- **QueueIndex**: The index of the queue. It will be -1 for priority levels without queues.
- **RequestIndexInQueue**: The index in the queue for a given request. It will be -1 for executing requests.
- **InitialSeats**: The number of seats will be occupied during the initial (normal) stage of execution of the request.
- **FinalSeats**: The number of seats will be occupied during the final stage of request execution, accounting for the associated WATCH notifications.
- **AdditionalLatency**: The extra time taken during the final stage of request execution. FinalSeats will be occupied during this time period. It does not mean any latency that a user will observe.
- **StartTime**: The time a request starts to execute. It will be 0001-01-01T00:00:00Z for queued requests.

## Debug logging

At `-v=3` or more verbosity, the API server outputs an `httplog` line for every request in the API server log, and it includes the following attributes.

- `apf_fs`: the name of the flow schema to which the request was classified.
- `apf_pl`: the name of the priority level for that flow schema.
- `apf_iseats`: the number of seats determined for the initial (normal) stage of execution of the request.
- `apf_fseats`: the number of seats determined for the final stage of execution (accounting for the associated watch notifications) of the request.
- `apf_additionalLatency`: the duration of the final stage of execution of the request.

At higher levels of verbosity there will be log lines exposing details of how APF handled the request, primarily for debugging purposes.

## Response headers

APF adds the following two headers to each HTTP response message. They won't appear in the audit log. They can be viewed from the client side. For client using `klog`, use verbosity `-v=8` or higher to view these headers.

- `X-Kubernetes-PF-FlowSchema-UID` holds the UID of the FlowSchema object to which the corresponding request was classified.
- `X-Kubernetes-PF-PriorityLevel-UID` holds the UID of the PriorityLevelConfiguration object associated with that FlowSchema.

## What's next

## Resource Types

- [ExecCredential](#)

## ExecCredential

ExecCredential is used by exec-based plugins to communicate credentials to HTTP transports.

| Field                                                        | Description                                                                                                   |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                         | client.authentication.k8s.io/v1                                                                               |
| kind<br>string                                               | ExecCredential                                                                                                |
| spec <b>[Required]</b><br><a href="#">ExecCredentialSpec</a> | Spec holds information passed to the plugin by the transport.                                                 |
| status<br><a href="#">ExecCredentialStatus</a>               | Status is filled in by the plugin and holds the credentials that the transport should use to contact the API. |

## Cluster

Appears in:

- [ExecCredentialSpec](#)

Cluster contains information to allow an exec plugin to communicate with the kubernetes cluster being authenticated to.

To ensure that this struct contains everything someone would need to communicate with a kubernetes cluster (just like they would via a kubeconfig), the fields should shadow "k8s.io/client-go/tools/clientcmd/api/v1".Cluster, with the exception of CertificateAuthority, since CA data will always be passed to the plugin as bytes.

| Field                              | Description                                                                                                                                                                            |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <b>[Required]</b><br>string | Server is the address of the kubernetes cluster (https://hostname:port).                                                                                                               |
| tls-server-name<br>string          | TLSServerName is passed to the server for SNI and is used in the client to check server certificates against. If ServerName is empty, the hostname used to contact the server is used. |

| Field                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| insecure-skip-tls-verify<br>bool                                                                                          | InsecureSkipTLSVerify skips the validity check for the server's certificate. This will make your HTTPS connections insecure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| certificate-authority-data<br>[]byte                                                                                      | CAData contains PEM-encoded certificate authority certificates. If empty, system roots should be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| proxy-url<br>string                                                                                                       | ProxyURL is the URL to the proxy to be used for all requests to this cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| disable-compression<br>bool                                                                                               | DisableCompression allows client to opt-out of response compression for all requests to the server. This is useful to speed up requests (specifically lists) when client-server network bandwidth is ample, by saving time on compression (server-side) and decompression (client-side): <a href="https://github.com/kubernetes/kubernetes/issues/112296">https://github.com/kubernetes/kubernetes/issues/112296</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| config<br><a href="https://k8s.io/apimachinery/pkg/runtime.RawExtension">k8s.io/apimachinery/pkg/runtime.RawExtension</a> | <p>Config holds additional config data that is specific to the exec plugin with regards to the cluster being authenticated to.</p> <p>This data is sourced from the clientcmd Cluster object's extensions[client.authentication.k8s.io/exec] field:</p> <p>clusters:</p> <ul style="list-style-type: none"> <li>• name: my-cluster cluster: ... extensions: <ul style="list-style-type: none"> <li>◦ name: client.authentication.k8s.io/exec # reserved extension name for per cluster exec config extension: audience: 06e3fbd18de8 # arbitrary config</li> </ul> </li> </ul> <p>In some environments, the user config may be exactly the same across many clusters (i.e. call this exec plugin) minus some details that are specific to each cluster such as the audience. This field allows the per cluster config to be directly specified with the cluster info. Using this field to store secret data is not recommended as one of the prime benefits of exec plugins is that no secrets need to be stored directly in the kubeconfig.</p> |

## ExecCredentialSpec

Appears in:

- [ExecCredential](#)

ExecCredentialSpec holds request and runtime specific information provided by the transport.

| Field                                    | Description                                                                                                                                                                                                                                                         |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster<br><a href="#">Cluster</a>       | Cluster contains information to allow an exec plugin to communicate with the kubernetes cluster being authenticated to. Note that Cluster is non-nil only when provideClusterInfo is set to true in the exec provider config (i.e., ExecConfig.ProvideClusterInfo). |
| interactive<br><b>[Required]</b><br>bool | Interactive declares whether stdin has been passed to this exec plugin.                                                                                                                                                                                             |

## ExecCredentialStatus

Appears in:

- [ExecCredential](#)

ExecCredentialStatus holds credentials for the transport to use.

Token and ClientKeyData are sensitive fields. This data should only be transmitted in-memory between client and exec plugin process. Exec plugin itself should at least be protected via file permissions.

| Field                                                | Description                                                                |
|------------------------------------------------------|----------------------------------------------------------------------------|
| expirationTimestamp<br><a href="#">meta/v1.Time</a>  | ExpirationTimestamp indicates a time when the provided credentials expire. |
| token <b>[Required]</b><br>string                    | Token is a bearer token used by the client for request authentication.     |
| clientCertificateData<br><b>[Required]</b><br>string | PEM-encoded client TLS certificates (including intermediates, if any).     |
| clientKeyData <b>[Required]</b><br>string            | PEM-encoded private key for the above certificate.                         |

## Client Authentication (v1beta1)

### Resource Types

- [ExecCredential](#)

## ExecCredential

ExecCredential is used by exec-based plugins to communicate credentials to HTTP transports.

| Field                                                        | Description                                                                                                   |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                         | client.authentication.k8s.io/v1beta1                                                                          |
| kind<br>string                                               | ExecCredential                                                                                                |
| spec <b>[Required]</b><br><a href="#">ExecCredentialSpec</a> | Spec holds information passed to the plugin by the transport.                                                 |
| status<br><a href="#">ExecCredentialStatus</a>               | Status is filled in by the plugin and holds the credentials that the transport should use to contact the API. |

## Cluster

### Appears in:

- [ExecCredentialSpec](#)

Cluster contains information to allow an exec plugin to communicate with the kubernetes cluster being authenticated to.

To ensure that this struct contains everything someone would need to communicate with a kubernetes cluster (just like they would via a kubeconfig), the fields should shadow "k8s.io/client-go/tools/clientcmd/api/v1".Cluster, with the exception of CertificateAuthority, since CA data will always be passed to the plugin as bytes.

| Field                                | Description                                                                                                                                                                            |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <b>[Required]</b><br>string   | Server is the address of the kubernetes cluster (https://hostname:port).                                                                                                               |
| tls-server-name<br>string            | TLSServerName is passed to the server for SNI and is used in the client to check server certificates against. If ServerName is empty, the hostname used to contact the server is used. |
| insecure-skip-tls-verify<br>bool     | InsecureSkipTLSVerify skips the validity check for the server's certificate. This will make your HTTPS connections insecure.                                                           |
| certificate-authority-data<br>[]byte | CAData contains PEM-encoded certificate authority certificates. If empty, system roots should be used.                                                                                 |
| proxy-url<br>string                  | ProxyURL is the URL to the proxy to be used for all requests to this cluster.                                                                                                          |
| disable-compression<br>bool          | DisableCompression allows client to opt-out of response compression for all requests to the server. This is useful to speed up requests                                                |

| Field                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| config<br><a href="https://k8s.io/apimachinery/pkg/runtime.RawExtension">k8s.io/apimachinery/pkg/runtime.RawExtension</a> | <p>Config holds additional config data that is specific to the exec plugin with regards to the cluster being authenticated to.</p> <p>This data is sourced from the clientcmd Cluster object's extensions[client.authentication.k8s.io/exec] field:</p> <p>clusters:</p> <ul style="list-style-type: none"> <li>• name: my-cluster cluster: ... extensions:               <ul style="list-style-type: none"> <li>◦ name: client.authentication.k8s.io/exec # reserved extension name for per cluster exec config extension: audience: 06e3fbd18de8 # arbitrary config</li> </ul> </li> </ul> <p>In some environments, the user config may be exactly the same across many clusters (i.e. call this exec plugin) minus some details that are specific to each cluster such as the audience. This field allows the per cluster config to be directly specified with the cluster info. Using this field to store secret data is not recommended as one of the prime benefits of exec plugins is that no secrets need to be stored directly in the kubeconfig.</p> |

## ExecCredentialSpec

Appears in:

- [ExecCredential](#)

ExecCredentialSpec holds request and runtime specific information provided by the transport.

| Field                                    | Description                                                                                                                                                                                                                                                         |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cluster<br><a href="#">Cluster</a>       | Cluster contains information to allow an exec plugin to communicate with the kubernetes cluster being authenticated to. Note that Cluster is non-nil only when provideClusterInfo is set to true in the exec provider config (i.e., ExecConfig.ProvideClusterInfo). |
| interactive<br><b>[Required]</b><br>bool | Interactive declares whether stdin has been passed to this exec plugin.                                                                                                                                                                                             |

## ExecCredentialStatus

Appears in:

- [ExecCredential](#)

ExecCredentialStatus holds credentials for the transport to use.

Token and ClientKeyData are sensitive fields. This data should only be transmitted in-memory between client and exec plugin process. Exec plugin itself should at least be protected via file permissions.

| Field                                               | Description                                                                |
|-----------------------------------------------------|----------------------------------------------------------------------------|
| expirationTimestamp<br><a href="#">meta/v1.Time</a> | ExpirationTimestamp indicates a time when the provided credentials expire. |
| token <b>[Required]</b><br>string                   | Token is a bearer token used by the client for request authentication.     |
| clientCertificateData <b>[Required]</b><br>string   | PEM-encoded client TLS certificates (including intermediates, if any).     |
| clientKeyData <b>[Required]</b><br>string           | PEM-encoded private key for the above certificate.                         |

## Event Rate Limit Configuration (v1alpha1)

### Resource Types

- [Configuration](#)

### Configuration

Configuration provides configuration for the EventRateLimit admission controller.

| Field                                               | Description                                                                                                                                                                                    |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                | eventratelimit.admission.k8s.io/v1alpha1                                                                                                                                                       |

| limits <b>[Required]</b><br><a href="#">[]Limit</a> | limits are the limits to place on event queries received. Limits can be placed on events received server-wide, per namespace, per user, and per source+object. At least one limit is required. |

### Limit

Appears in:

- [Configuration](#)

Limit is the configuration for a particular limit type

| Field                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type<br>[Required]<br><a href="#">LimitType</a> | type is the type of limit to which this configuration applies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| qps<br>[Required]<br>int32                      | qps is the number of event queries per second that are allowed for this type of limit. The qps and burst fields are used together to determine if a particular event query is accepted. The qps determines how many queries are accepted once the burst amount of queries has been exhausted.                                                                                                                                                                                                                                                                                               |
| burst<br>[Required]<br>int32                    | burst is the burst number of event queries that are allowed for this type of limit. The qps and burst fields are used together to determine if a particular event query is accepted. The burst determines the maximum size of the allowance granted for a particular bucket. For example, if the burst is 10 and the qps is 3, then the admission control will accept 10 queries before blocking any queries. Every second, 3 more queries will be allowed. If some of that allowance is not used, then it will roll over to the next second, until the maximum allowance of 10 is reached. |
| cacheSize<br>int32                              | <p>cacheSize is the size of the LRU cache for this type of limit. If a bucket is evicted from the cache, then the allowance for that bucket is reset. If more queries are later received for an evicted bucket, then that bucket will re-enter the cache with a clean slate, giving that bucket a full allowance of burst queries.</p> <p>The default cache size is 4096.</p> <p>If limitType is 'server', then cacheSize is ignored.</p>                                                                                                                                                   |

## LimitType

(Alias of string)

Appears in:

- [Limit](#)

LimitType is the type of the limit (e.g., per-namespace)

## Image Policy API (v1alpha1)

### Resource Types

- [ImageReview](#)

## ImageReview

ImageReview checks if the set of images in a pod are allowed.

|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | Annotations is a list of key-value pairs extracted from the Pod's annotations. It only includes keys which match the pattern *.image-policy.k8s.io/*. It is up to each webhook backend to determine how to interpret these annotations, if at all. |
| namespace<br>string | Namespace is the namespace the pod is being created in.                                                                                                                                                                                            |

## ImageReviewStatus

Appears in:

- [ImageReview](#)

ImageReviewStatus is the result of the review for the pod creation request.

| Field                                 | Description                                                                                                                                                                                                        |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allowed<br>[Required]<br>bool         | Allowed indicates that all images were allowed to be run.                                                                                                                                                          |
| reason<br>string                      | Reason should be empty unless Allowed is false in which case it may contain a short description of what is wrong. Kubernetes may truncate excessively long errors when displaying to the user.                     |
| auditAnnotations<br>map[string]string | AuditAnnotations will be added to the attributes object of the admission controller request using 'AddAnnotation'. The keys should be prefix-less (i.e., the admission controller will add an appropriate prefix). |

# kube-apiserver Admission (v1)

## Resource Types

- [AdmissionReview](#)

## AdmissionReview

AdmissionReview describes an admission review request/response.

| Field                | Description         |
|----------------------|---------------------|
| apiVersion<br>string | admission.k8s.io/v1 |
| kind<br>string       | AdmissionReview     |

| Field                                         | Description                                                   |
|-----------------------------------------------|---------------------------------------------------------------|
| request<br><a href="#">AdmissionRequest</a>   | Request describes the attributes for the admission request.   |
| response<br><a href="#">AdmissionResponse</a> | Response describes the attributes for the admission response. |

## AdmissionRequest

Appears in:

- [AdmissionReview](#)

AdmissionRequest describes the admission.Attributes for the admission request.

| Field                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uid <b>[Required]</b><br><a href="#">k8s.io/apimachinery/pkg/types.UID</a> | UID is an identifier for the individual request/response. It allows us to distinguish instances of requests which are otherwise identical (parallel requests, requests when earlier requests did not modify etc) The UID is meant to track the round trip (request/response) between the KAS and the WebHook, not the user request. It is suitable for correlating log entries between the webhook and apiserver, for either auditing or debugging.                                                                                                                                                                                                                                                                                                                                  |
| kind <b>[Required]</b><br><a href="#">meta/v1.GroupVersionKind</a>         | Kind is the fully-qualified type of object being submitted (for example, v1.Pod or autoscaling.v1.Scale)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| resource <b>[Required]</b><br><a href="#">meta/v1.GroupVersionResource</a> | Resource is the fully-qualified resource being requested (for example, v1.pods)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| subResource<br>string                                                      | SubResource is the subresource being requested, if any (for example, "status" or "scale")                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| requestKind<br><a href="#">meta/v1.GroupVersionKind</a>                    | <p>RequestKind is the fully-qualified type of the original API request (for example, v1.Pod or autoscaling.v1.Scale). If this is specified and differs from the value in "kind", an equivalent match and conversion was performed.</p> <p>For example, if deployments can be modified via apps/v1 and apps/v1beta1, and a webhook registered a rule of apiGroups:["apps"], apiVersions:["v1"], resources: ["deployments"] and matchPolicy: Equivalent, an API request to apps/v1beta1 deployments would be converted and sent to the webhook with kind: {group:"apps", version:"v1", kind:"Deployment"} (matching the rule the webhook registered for), and requestKind: {group:"apps", version:"v1beta1", kind:"Deployment"} (indicating the kind of the original API request).</p> |

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| auditAnnotations<br>map[string]string                                                                       | AuditAnnotations is an unstructured key value map set by remote admission controller (e.g. error=image-blacklisted). MutatingAdmissionWebhook and ValidatingAdmissionWebhook admission controller will prefix the keys with admission webhook name (e.g. imagepolicy.example.com/error=image-blacklisted). AuditAnnotations |

| Field                | Description                                                                                                                                                                                                                                                                                                    |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | will be provided by the admission webhook to add additional context to the audit log for this request.                                                                                                                                                                                                         |
| warnings<br>[]string | warnings is a list of warning messages to return to the requesting API client. Warning messages describe a problem the client making the API request should correct or be aware of. Limit warnings to 120 characters if possible. Warnings over 256 characters and large numbers of warnings may be truncated. |

## Operation

(Alias of string)

**Appears in:**

- [AdmissionRequest](#)

Operation is the type of resource operation being checked for admission control

## PatchType

(Alias of string)

**Appears in:**

- [AdmissionResponse](#)

PatchType is the type of patch being used to represent the mutated object

# kube-apiserver Audit Configuration (v1)

## Resource Types

- [Event](#)
- [EventList](#)
- [Policy](#)
- [PolicyList](#)

## Event

**Appears in:**

- [EventList](#)

Event captures all the information that can be included in an API audit log.

| responseStatus<br><a href="#">meta/v1.Status</a>                          | The response status, populated even when the ResponseObject is not a Status type. For successful responses, this will only include the Code and StatusSuccess. For non-status type error responses, this will be auto-populated with the error Message.                                                                                                                                                                                                                                                                                          |
| requestObject<br><a href="#">k8s.io/apimachinery/pkg/runtime.Unknown</a>  | API object from the request, in JSON format. The RequestObject is recorded as-is in the request (possibly re-encoded as JSON), prior to version conversion, defaulting, admission or merging. It is an external versioned object type, and may not be a valid object on its own. Omitted for non-resource requests. Only logged at Request Level and higher.                                                                                                                                                                                     |
| responseObject<br><a href="#">k8s.io/apimachinery/pkg/runtime.Unknown</a> | API object returned in the response, in JSON. The ResponseObject is recorded after conversion to the external type, and serialized as JSON. Omitted for non-resource requests. Only logged at Response Level.                                                                                                                                                                                                                                                                                                                                    |
| requestReceivedTimestamp<br><a href="#">meta/v1.MicroTime</a>             | Time the request reached the apiserver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| stageTimestamp<br><a href="#">meta/v1.MicroTime</a>                       | Time the request reached current audit stage.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| annotations<br>map[string]string                                          | Annotations is an unstructured key value map stored with an audit event that may be set by plugins invoked in the request serving chain, including authentication, authorization and admission plugins. Note that these annotations are for the audit event, and do not correspond to the metadata.annotations of the submitted object. Keys should uniquely identify the informing component to avoid name collisions (e.g. podsecuritypolicy.admission.k8s.io/policy). Values should be short. Annotations are included in the Metadata level. |

## EventList

EventList is a list of audit Events.

| Field                                              | Description              |
|----------------------------------------------------|--------------------------|
| apiVersion<br>string                               | audit.k8s.io/v1          |
| kind<br>string                                     | EventList                |
| metadata<br><a href="#">meta/v1.ListMeta</a>       | No description provided. |
| items <b>[Required]</b><br><a href="#">[]Event</a> | No description provided. |

# Policy

Appears in:

- [PolicyList](#)

Policy defines the configuration of audit logging, and the rules for how different request categories are logged.

| Field                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |

# PolicyRule

Appears in:

- [Policy](#)

PolicyRule maps requests based off metadata to an audit Level. Requests must match the rules of every field (an intersection of rules).

| Field                                              | Description                                                                                    |
|----------------------------------------------------|------------------------------------------------------------------------------------------------|
| level [ <b>Required</b> ]<br><a href="#">Level</a> | The Level that requests matching this rule are recorded at.                                    |
| users<br>[]string                                  | The users (by authenticated user name) this rule applies to. An empty list implies every user. |

| Field                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| userGroups<br>[]string                        | The user groups this rule applies to. A user is considered matching if it is a member of any of the UserGroups. An empty list implies every user group.                                                                                                                                                                                                                                                                                                                                                                                                             |
| verbs<br>[]string                             | The verbs that match this rule. An empty list implies every verb.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| resources<br><a href="#">[]GroupResources</a> | Resources that this rule matches. An empty list implies all kinds in all API groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| namespaces<br>[]string                        | Namespaces that this rule matches. The empty string "" matches non-namespaced resources. An empty list implies every namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| nonResourceURLs<br>[]string                   | NonResourceURLs is a set of URL paths that should be audited. *s are allowed, but only as the full, final step in the path. Examples: <ul style="list-style-type: none"> <li>• /metrics - Log requests for apiserver metrics</li> <li>• /healthz* - Log all health checks</li> </ul>                                                                                                                                                                                                                                                                                |
| omitStages<br><a href="#">[]Stage</a>         | OmitStages is a list of stages for which no events are created. Note that this can also be specified policy wide in which case the union of both are omitted. An empty list means no restrictions will apply.                                                                                                                                                                                                                                                                                                                                                       |
| omitManagedFields<br>bool                     | OmitManagedFields indicates whether to omit the managed fields of the request and response bodies from being written to the API audit log. <ul style="list-style-type: none"> <li>• a value of 'true' will drop the managed fields from the API audit log</li> <li>• a value of 'false' indicates that the managed fields should be included in the API audit log Note that the value, if specified, in this rule will override the global default If a value is not specified then the global default specified in Policy.OmitManagedFields will stand.</li> </ul> |

## Stage

(Alias of string)

**Appears in:**

- [Event](#)
- [Policy](#)
- [PolicyRule](#)

Stage defines the stages in request handling that audit events may be generated.

# kube-apiserver Configuration (v1)

Package v1 is the v1 version of the API.

## Resource Types

- [AdmissionConfiguration](#)
- [EncryptionConfiguration](#)

## AdmissionConfiguration

AdmissionConfiguration provides versioned configuration for admission controllers.

| Field                                                     | Description                                                             |
|-----------------------------------------------------------|-------------------------------------------------------------------------|
| apiVersion<br>string                                      | apiserver.config.k8s.io/v1                                              |
| kind<br>string                                            | AdmissionConfiguration                                                  |
| plugins<br><a href="#">[]AdmissionPluginConfiguration</a> | Plugins allows specifying a configuration per admission control plugin. |

## EncryptionConfiguration

EncryptionConfiguration stores the complete configuration for encryption providers. It also allows the use of wildcards to specify the resources that should be encrypted. Use '\*.<group>' to encrypt all resources within a group or '\*' to encrypt all resources. '\*' can be used to encrypt all resource in the core group. '\*' will encrypt all resources, even custom resources that are added after API server start. Use of wildcards that overlap within the same resource list or across multiple entries are not allowed since part of the configuration would be ineffective. Resource lists are processed in order, with earlier lists taking precedence.

Example:

```
kind: EncryptionConfiguration
apiVersion: apiserver.config.k8s.io/v1
resources:
- resources:
 - events
 providers:
 - identity: {} # do not encrypt events even though '*' is specified below
- resources:
 - secrets
 - configmaps
 - pandas.awesome.bears.example
 providers:
 - aescbc:
 keys:
```

```

- name: key1
 secret: c2VjcmV0IGlzIHNIY3VyZQ==
- resources:
 - '*.apps'
providers:
- aescbc:
 keys:
 - name: key2
 secret: c2VjcmV0IGlzIHNIY3VyZSwgb3IgaXMgaXQ/Cg==
- resources:
 - '**'
providers:
- aescbc:
 keys:
 - name: key3
 secret: c2VjcmV0IGlzIHNIY3VyZSwgSSB0aGluaw==

```

| Field                                                                  | Description                                                                             |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| apiVersion<br>string                                                   | apiserver.config.k8s.io/v1                                                              |
| kind<br>string                                                         | EncryptionConfiguration                                                                 |
| resources <b>[Required]</b><br><a href="#">[]ResourceConfiguration</a> | resources is a list containing resources, and their corresponding encryption providers. |

## AESConfiguration

Appears in:

- [ProviderConfiguration](#)

AESConfiguration contains the API configuration for an AES transformer.

| Field                                              | Description                                                                                                                                          |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| keys<br><b>[Required]</b><br><a href="#">[]Key</a> | keys is a list of keys to be used for creating the AES transformer. Each key has to be 32 bytes long for AES-CBC and 16, 24 or 32 bytes for AES-GCM. |

## AdmissionPluginConfiguration

Appears in:

- [AdmissionConfiguration](#)

AdmissionPluginConfiguration provides the configuration for a single plug-in.

| Field                                                                                                                  | Description                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name <b>[Required]</b><br>string                                                                                       | Name is the name of the admission controller. It must match the registered admission plugin name.                                                                      |
| path<br>string                                                                                                         | Path is the path to a configuration file that contains the plugin's configuration                                                                                      |
| configuration<br><a href="https://k8s.io/apimachinery/pkg/runtime.Unknown">k8s.io/apimachinery/pkg/runtime.Unknown</a> | Configuration is an embedded configuration object to be used as the plugin's configuration. If present, it will be used instead of the path to the configuration file. |

## IdentityConfiguration

Appears in:

- [ProviderConfiguration](#)

IdentityConfiguration is an empty struct to allow identity transformer in provider configuration.

## KMSConfiguration

Appears in:

- [ProviderConfiguration](#)

KMSConfiguration contains the name, cache size and path to configuration file for a KMS based envelope transformer.

| Field                                       | Description                                                                                                                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                        | apiVersion of KeyManagementService                                                                                                                                                             |
| name<br><b>[Required]</b><br>string         | name is the name of the KMS plugin to be used.                                                                                                                                                 |
| cachesize<br>int32                          | cachesize is the maximum number of secrets which are cached in memory. The default value is 1000. Set to a negative value to disable caching. This field is only allowed for KMS v1 providers. |
| endpoint<br><b>[Required]</b><br>string     | endpoint is the gRPC server listening address, for example "unix:///var/run/kms-provider.sock".                                                                                                |
| timeout<br><a href="#">meta/v1.Duration</a> | timeout for gRPC calls to kms-plugin (ex. 5s). The default is 3 seconds.                                                                                                                       |

## Key

Appears in:

- [AESConfiguration](#)
- [SecretboxConfiguration](#)

Key contains name and secret of the provided key for a transformer.

| Field                              | Description                                                        |
|------------------------------------|--------------------------------------------------------------------|
| name <b>[Required]</b><br>string   | name is the name of the key to be used while storing data to disk. |
| secret <b>[Required]</b><br>string | secret is the actual key, encoded in base64.                       |

## ProviderConfiguration

Appears in:

- [ResourceConfiguration](#)

ProviderConfiguration stores the provided configuration for an encryption provider.

| Field                                                                 | Description                                                                                            |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| aesgcm <b>[Required]</b><br><a href="#">AESConfiguration</a>          | aesgcm is the configuration for the AES-GCM transformer.                                               |
| aescbc <b>[Required]</b><br><a href="#">AESConfiguration</a>          | aescbc is the configuration for the AES-CBC transformer.                                               |
| secretbox <b>[Required]</b><br><a href="#">SecretboxConfiguration</a> | secretbox is the configuration for the Secretbox based transformer.                                    |
| identity <b>[Required]</b><br><a href="#">IdentityConfiguration</a>   | identity is the (empty) configuration for the identity transformer.                                    |
| kms <b>[Required]</b><br><a href="#">KMSConfiguration</a>             | kms contains the name, cache size and path to configuration file for a KMS based envelope transformer. |

## ResourceConfiguration

Appears in:

- [EncryptionConfiguration](#)

ResourceConfiguration stores per resource configuration.

| Field                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| resources <b>[Required]</b><br>[]string                                | resources is a list of kubernetes resources which have to be encrypted. The resource names are derived from resource or resource.group of the group/version/resource. eg: pandas.awesome.bears.example is a custom resource with 'group': awesome.bears.example, 'resource': pandas. Use '*' to encrypt all resources and '*.<group>' to encrypt all resources in a specific group. eg: '*.awesome.bears.example' will encrypt all resources in the group 'awesome.bears.example'. eg: '*' will encrypt all resources in the core group (such as pods, configmaps, etc). |
| providers <b>[Required]</b><br><a href="#">[]ProviderConfiguration</a> | providers is a list of transformers to be used for reading and writing the resources to disk. eg: aesgcm, aescbc, secretbox, identity, kms.                                                                                                                                                                                                                                                                                                                                                                                                                              |

## SecretboxConfiguration

Appears in:

- [ProviderConfiguration](#)

SecretboxConfiguration contains the API configuration for an Secretbox transformer.

| Field                                           | Description                                                                                                 |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| keys <b>[Required]</b><br><a href="#">[]Key</a> | keys is a list of keys to be used for creating the Secretbox transformer. Each key has to be 32 bytes long. |

## kube-apiserver Configuration (v1alpha1)

Package v1alpha1 is the v1alpha1 version of the API.

### Resource Types

- [AdmissionConfiguration](#)
- [AuthenticationConfiguration](#)
- [AuthorizationConfiguration](#)
- [EgressSelectorConfiguration](#)
- [TracingConfiguration](#)

### TracingConfiguration

Appears in:

- [KubeletConfiguration](#)
- [TracingConfiguration](#)

TracingConfiguration provides versioned configuration for OpenTelemetry tracing clients.

| Field                           | Description                                                                                                                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endpoint<br>string              | Endpoint of the collector this component will report traces to. The connection is insecure, and does not currently support TLS. Recommended is unset, and endpoint is the otel grpc default, localhost:4317. |
| samplingRatePerMillion<br>int32 | SamplingRatePerMillion is the number of samples to collect per million spans. Recommended is unset. If unset, sampler respects its parent span's sampling rate, but otherwise never samples.                 |

## AdmissionConfiguration

AdmissionConfiguration provides versioned configuration for admission controllers.

| Field                                                     | Description                                                             |
|-----------------------------------------------------------|-------------------------------------------------------------------------|
| apiVersion<br>string                                      | apiserver.k8s.io/v1alpha1                                               |
| kind<br>string                                            | AdmissionConfiguration                                                  |
| plugins<br><a href="#">[]AdmissionPluginConfiguration</a> | Plugins allows specifying a configuration per admission control plugin. |

## AuthenticationConfiguration

AuthenticationConfiguration provides versioned configuration for authentication.

| Field                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| apiVersion<br>string                                 | apiserver.k8s.io/v1alpha1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| kind<br>string                                       | AuthenticationConfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| jwt [Required]<br><a href="#">[]JWTAuthenticator</a> | jwt is a list of authenticator to authenticate Kubernetes users using JWT compliant tokens. The authenticator will attempt to parse a raw ID token, verify it's been signed by the configured issuer. The public key to verify the signature is discovered from the issuer's public endpoint using OIDC discovery. For an incoming token, each JWT authenticator will be attempted in the order in which it is specified in this list. Note however that other authenticators may run before or after the JWT authenticators. The specific position of JWT authenticators in relation to other authenticators is neither defined nor stable across releases. Since each JWT authenticator must have a unique issuer URL, at most one JWT authenticator will attempt to cryptographically validate the token. |

| Field | Description                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | The minimum valid JWT payload must contain the following claims: {<br>"iss": "https://issuer.example.com", "aud": ["audience"], "exp": 1234567890,<br>"<username claim>": "username" } |

## AuthorizationConfiguration

| Field                                                                       | Description                                                                                                                                                         |
|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                        | apiserver.k8s.io/v1alpha1                                                                                                                                           |
| kind<br>string                                                              | AuthorizationConfiguration                                                                                                                                          |
| authorizers <b>[Required]</b><br><a href="#">[] AuthorizerConfiguration</a> | Authorizers is an ordered list of authorizers to authorize requests against. This is similar to the --authorization-modes kube-apiserver flag Must be at least one. |

## EgressSelectorConfiguration

EgressSelectorConfiguration provides versioned configuration for egress selector clients.

| Field                                                                       | Description                                                                  |
|-----------------------------------------------------------------------------|------------------------------------------------------------------------------|
| apiVersion<br>string                                                        | apiserver.k8s.io/v1alpha1                                                    |
| kind<br>string                                                              | EgressSelectorConfiguration                                                  |
| egressSelections<br><b>[Required]</b><br><a href="#">[] EgressSelection</a> | connectionServices contains a list of egress selection client configurations |

## TracingConfiguration

TracingConfiguration provides versioned configuration for tracing clients.

| Field                                                                             | Description                                                                                                                   |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                              | apiserver.k8s.io/v1alpha1                                                                                                     |
| kind<br>string                                                                    | TracingConfiguration                                                                                                          |
| TracingConfiguration<br><b>[Required]</b><br><a href="#">TracingConfiguration</a> | (Members of TracingConfiguration are embedded into this type.)<br><br>Embed the component config tracing configuration struct |

## AdmissionPluginConfiguration

Appears in:

- [AdmissionConfiguration](#)

AdmissionPluginConfiguration provides the configuration for a single plug-in.

| Field                                                                                                                  | Description                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name <b>[Required]</b><br>string                                                                                       | Name is the name of the admission controller. It must match the registered admission plugin name.                                                                      |
| path<br>string                                                                                                         | Path is the path to a configuration file that contains the plugin's configuration                                                                                      |
| configuration<br><a href="https://k8s.io/apimachinery/pkg/runtime.Unknown">k8s.io/apimachinery/pkg/runtime.Unknown</a> | Configuration is an embedded configuration object to be used as the plugin's configuration. If present, it will be used instead of the path to the configuration file. |

## AudienceMatchPolicyType

(Alias of string)

Appears in:

- [Issuer](#)

AudienceMatchPolicyType is a set of valid values for issuer.audienceMatchPolicy

## AuthorizerConfiguration

Appears in:

- [AuthorizationConfiguration](#)

| Field                            | Description                                                                                                                                                                                                                     |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type <b>[Required]</b><br>string | Type refers to the type of the authorizer "Webhook" is supported in the generic API server Other API servers may support additional authorizer types like Node, RBAC, ABAC, etc.                                                |
| name <b>[Required]</b><br>string | Name used to describe the webhook This is explicitly used in monitoring machinery for metrics Note: Names must be DNS1123 labels like myauthorizername or subdomains like myauthorizer.example.domain Required, with no default |

## ClaimMappings

Appears in:

- [JWTAuthenticator](#)

ClaimMappings provides the configuration for claim mapping

| Field                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| username <b>[Required]</b><br><a href="#">PrefixedClaimOrExpression</a> | <p>username represents an option for the username attribute. The claim's value must be a singular string. Same as the --oidc-username-claim and --oidc-username-prefix flags. If username.expression is set, the expression must produce a string value. If username.expression uses 'claims.email', then 'claims.email_verified' must be used in username.expression or extra[*].valueExpression or claimValidationRules[*].expression. An example claim validation rule expression that matches the validation automatically applied when username.claim is set to 'email' is 'claims.?email_verified.orValue(true)'.</p> <p>In the flag based approach, the --oidc-username-claim and --oidc-username-prefix are optional. If --oidc-username-claim is not set, the default value is "sub". For the authentication config, there is no defaulting for claim or prefix. The claim and prefix must be set explicitly. For claim, if --oidc-username-claim was not set with legacy flag approach, configure username.claim="sub" in the authentication config. For prefix: (1) --oidc-username-prefix="-", no prefix was added to the username. For the same behavior using authentication config, set username.prefix="" (2) --oidc-username-prefix="" and --oidc-username-claim != "email", prefix was "&lt;value of --oidc-issuer-url&gt;#". For the same behavior using authentication config, set username.prefix="&lt;value of issuer.url&gt;#" (3) --oidc-username-prefix="&lt;value&gt;". For the same behavior using authentication config, set username.prefix="&lt;value&gt;"</p> |
| groups<br><a href="#">PrefixedClaimOrExpression</a>                     | groups represents an option for the groups attribute. The claim's value must be a string or string array claim. If groups.claim is set, the prefix must be specified (and can be the empty string). If groups.expression is set, the expression must produce a string or string array value. "", [], and null values are treated as the group mapping not being present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Field                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## ClaimValidationRule

Appears in:

- [JWTAuthenticator](#)

ClaimValidationRule provides the configuration for a single claim validation rule.

| Field                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| claim<br>string         | claim is the name of a required claim. Same as --oidc-required-claim flag. Only string claim keys are supported. Mutually exclusive with expression and message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| requiredValue<br>string | requiredValue is the value of a required claim. Same as --oidc-required-claim flag. Only string claim values are supported. If claim is set and requiredValue is not set, the claim must be present with a value set to the empty string. Mutually exclusive with expression and message.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| expression<br>string    | <p>expression represents the expression which will be evaluated by CEL. Must produce a boolean.</p> <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"> <li>• 'claims' is a map of claim names to claim values. For example, a variable named 'sub' can be accessed as 'claims.sub'. Nested claims can be accessed using dot notation, e.g. 'claims.foo.bar'. Must return true for the validation to pass.</li> </ul> <p>Documentation on CEL: <a href="https://kubernetes.io/docs/reference/using-api/cel/">https://kubernetes.io/docs/reference/using-api/cel/</a><br/><br/>Mutually exclusive with claim and requiredValue.</p> |
| message<br>string       | message customizes the returned error message when expression returns false. message is a literal string. Mutually exclusive with claim and requiredValue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Connection

Appears in:

- [EgressSelection](#)

Connection provides the configuration for a single egress selection client.

| Field                                                       | Description                                                                                                                                         |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| proxyProtocol<br>[Required]<br><a href="#">ProtocolType</a> | Protocol is the protocol used to connect from client to the konnectivity server.                                                                    |
| transport<br><a href="#">Transport</a>                      | Transport defines the transport configurations we use to dial to the konnectivity server. This is required if ProxyProtocol is HTTPConnect or GRPC. |

## EgressSelection

Appears in:

- [EgressSelectorConfiguration](#)

EgressSelection provides the configuration for a single egress selection client.

| Field                                                  | Description                                                                                                                                                                                   |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name<br>[Required]<br>string                           | name is the name of the egress selection. Currently supported values are "controlplane", "master", "etcd" and "cluster" The "master" egress selector is deprecated in favor of "controlplane" |
| connection<br>[Required]<br><a href="#">Connection</a> | connection is the exact information used to configure the egress selection                                                                                                                    |

## ExtraMapping

Appears in:

- [ClaimMappings](#)

ExtraMapping provides the configuration for a single extra mapping.

| Field                                   | Description                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key [Required]<br>string                | key is a string to use as the extra attribute key. key must be a domain-prefix path (e.g. example.org/foo). All characters before the first "/" must be a valid subdomain as defined by RFC 1123. All characters trailing the first "/" must be valid HTTP Path characters as defined by RFC 3986. key must be lowercase. Required to be unique. |
| valueExpression<br>[Required]<br>string | valueExpression is a CEL expression to extract extra attribute value. valueExpression must produce a string or string array value. "", [], and null values are treated as the extra mapping not being present. Empty string values contained within a string array are filtered out.                                                             |

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"> <li>'claims' is a map of claim names to claim values. ## Issuer

Appears in:

- [JWTAuthenticator](#)

Issuer provides the configuration for an external provider's specific settings.

| Field                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url <b>[Required]</b><br>string | <p>url points to the issuer URL in a format https://url or https://url/path. This must match the "iss" claim in the presented JWT, and the issuer returned from discovery. Same value as the --oidc-issuer-url flag. Discovery information is fetched from "{url}/.well-known/openid-configuration" unless overridden by discoveryURL. Required to be unique across all JWT authenticators. Note that egress selection configuration is not used for this network connection.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| discoveryURL<br>string          | <p>discoveryURL, if specified, overrides the URL used to fetch discovery information instead of using "{url}/.well-known/openid-configuration". The exact value specified is used, so "/.well-known/openid-configuration" must be included in discoveryURL if needed.</p> <p>The "issuer" field in the fetched discovery information must match the "issuer.url" field in the AuthenticationConfiguration and will be used to validate the "iss" claim in the presented JWT. This is for scenarios where the well-known and jwks endpoints are hosted at a different location than the issuer (such as locally in the cluster).</p> <p>Example: A discovery url that is exposed using kubernetes service 'oidc' in namespace 'oidc-namespace' and discovery information is available at '/.well-known/openid-configuration'. discoveryURL: "https://oidc.oidc-namespace/.well-known/openid-configuration" certificateAuthority is used to verify the TLS connection and the hostname on the leaf certificate must be set to 'oidc.oidc-namespace'.</p> <p>curl https://oidc.oidc-namespace/.well-known/openid-configuration (.discoveryURL field) { issuer: "https://oidc.example.com" (.url field) }</p> |

| Field                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                             | discoveryURL must be different from url. Required to be unique across all JWT authenticators. Note that egress selection configuration is not used for this network connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| certificateAuthority string                                 | certificateAuthority contains PEM-encoded certificate authority certificates used to validate the connection when fetching discovery information. If unset, the system verifier is used. Same value as the content of the file referenced by the --oidc-ca-file flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| audiences [ <b>Required</b> ] []string                      | audiences is the set of acceptable audiences the JWT must be issued to. At least one of the entries must match the "aud" claim in presented JWTs. Same value as the --oidc-client-id flag (though this field supports an array). Required to be non-empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| audienceMatchPolicy <a href="#">AudienceMatchPolicyType</a> | <p>audienceMatchPolicy defines how the "audiences" field is used to match the "aud" claim in the presented JWT. Allowed values are:</p> <ol style="list-style-type: none"> <li>1. "MatchAny" when multiple audiences are specified and</li> <li>2. empty (or unset) or "MatchAny" when a single audience is specified.</li> </ol> <ul style="list-style-type: none"> <li>• MatchAny: the "aud" claim in the presented JWT must match at least one of the entries in the "audiences" field. For example, if "audiences" is ["foo", "bar"], the "aud" claim in the presented JWT must contain either "foo" or "bar" (and may contain both).</li> <li>• "": The match policy can be empty (or unset) when a single audience is specified in the "audiences" field. The "aud" claim in the presented JWT must contain the single audience (and may contain others).</li> </ul> <p>For more nuanced audience validation, use claimValidationRules. example: claimValidationRule[].expression: 'sets.equivalent(claims.aud, ["bar", "foo", "baz"])' to require an exact match.</p> |

## JWTAuthenticator

Appears in:

- [AuthenticationConfiguration](#)

JWTAuthenticator provides the configuration for a single JWT authenticator.

| Field                                                               | Description                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| issuer <b>[Required]</b><br><a href="#">Issuer</a>                  | issuer contains the basic OIDC provider connection options.                                                                                                                                                                                                                                                                                                        |
| claimValidationRules<br><a href="#">[]ClaimValidationRule</a>       | claimValidationRules are rules that are applied to validate token claims to authenticate users.                                                                                                                                                                                                                                                                    |
| claimMappings<br><b>[Required]</b><br><a href="#">ClaimMappings</a> | claimMappings points claims of a token to be treated as user attributes.                                                                                                                                                                                                                                                                                           |
| userValidationRules<br><a href="#">[]UserValidationRule</a>         | userValidationRules are rules that are applied to final user before completing authentication. These allow invariants to be applied to incoming identities such as preventing the use of the system: prefix that is commonly used by Kubernetes components. The validation rules are logically ANDed together and must all return true for the validation to pass. |

## PrefixedClaimOrExpression

Appears in:

- [ClaimMappings](#)

PrefixedClaimOrExpression provides the configuration for a single prefixed claim or expression.

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| claim string      | claim is the JWT claim to use. Mutually exclusive with expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| prefix string     | prefix is prepended to claim's value to prevent clashes with existing names. prefix needs to be set if claim is set and can be the empty string. Mutually exclusive with expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| expression string | <p>expression represents the expression which will be evaluated by CEL.</p> <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"> <li>• 'claims' is a map of claim names to claim values. For example, a variable named 'sub' can be accessed as 'claims.sub'. Nested claims can be accessed using dot notation, e.g. 'claims.foo.bar'.</li> </ul> <p>Documentation on CEL: <a href="https://kubernetes.io/docs/reference/using-api/cel/">https://kubernetes.io/docs/reference/using-api/cel/</a></p> <p>Mutually exclusive with claim and prefix.</p> |

## ProtocolType

(Alias of string)

**Appears in:**

- [Connection](#)

ProtocolType is a set of valid values for Connection.ProtocolType

## TCPTransport

**Appears in:**

- [Transport](#)

TCPTransport provides the information to connect to konnectivity server via TCP

| Field                                  | Description                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------|
| url<br>[Required]<br>string            | URL is the location of the konnectivity server to connect to. As an example it might be "https://127.0.0.1:8131" |
| tlsConfig<br><a href="#">TLSConfig</a> | TLSConfig is the config needed to use TLS when connecting to konnectivity server                                 |

## TLSConfig

**Appears in:**

- [TCPTransport](#)

TLSConfig provides the authentication information to connect to konnectivity server Only used with TCPTransport

| Field                | Description                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| caBundle<br>string   | caBundle is the file location of the CA to be used to determine trust with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// If absent while TCPTransport.URL is prefixed with https://, default to system trust roots. |
| clientKey<br>string  | clientKey is the file location of the client key to be used in mTLS handshakes with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// Must be configured if TCPTransport.URL is prefixed with https://                  |
| clientCert<br>string |                                                                                                                                                                                                                                                                  |

| Field | Description                                                                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | clientCert is the file location of the client certificate to be used in mTLS handshakes with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// Must be configured if TCPTransport.URL is prefixed with https:// |

## Transport

Appears in:

- [Connection](#)

Transport defines the transport configurations we use to dial to the konnectivity server

| Field                               | Description                                                                                                                                                                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcp<br><a href="#">TCPTransport</a> | TCP is the TCP configuration for communicating with the konnectivity server via TCP ProxyProtocol of GRPC is not supported with TCP transport at the moment Requires at least one of TCP or UDS to be set |
| uds<br><a href="#">UDSTransport</a> | UDS is the UDS configuration for communicating with the konnectivity server via UDS Requires at least one of TCP or UDS to be set                                                                         |

## UDSTransport

Appears in:

- [Transport](#)

UDSTransport provides the information to connect to konnectivity server via UDS

| Field                           | Description                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| udsName<br>[Required]<br>string | UDSName is the name of the unix domain socket to connect to konnectivity server This does not use a unix:// prefix. (Eg: /etc/srv/kubernetes/konnectivity-server/konnectivity-server.socket) |

## UserValidationRule

Appears in:

- [JWTAuthenticator](#)

UserValidationRule provides the configuration for a single user info validation rule.

| Field                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

- [AuthorizationConfiguration](#)
- [EgressSelectorConfiguration](#)
- [TracingConfiguration](#)

## TracingConfiguration

Appears in:

- [KubeletConfiguration](#)

[TracingConfiguration](#)

- [TracingConfiguration](#)

TracingConfiguration provides versioned configuration for OpenTelemetry tracing clients.

| Field                           | Description                                                                                                                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endpoint<br>string              | Endpoint of the collector this component will report traces to. The connection is insecure, and does not currently support TLS. Recommended is unset, and endpoint is the otel grpc default, localhost:4317. |
| samplingRatePerMillion<br>int32 | SamplingRatePerMillion is the number of samples to collect per million spans. Recommended is unset. If unset, sampler respects its parent span's sampling rate, but otherwise never samples.                 |

## AuthenticationConfiguration

AuthenticationConfiguration provides versioned configuration for authentication.

| Field                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| kind<br>string                                       | AuthenticationConfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| jwt [Required]<br><a href="#">[]JWTAuthenticator</a> | <p>jwt is a list of authenticator to authenticate Kubernetes users using JWT compliant tokens. The authenticator will attempt to parse a raw ID token, verify it's been signed by the configured issuer. The public key to verify the signature is discovered from the issuer's public endpoint using OIDC discovery. For an incoming token, each JWT authenticator will be attempted in the order in which it is specified in this list. Note however that other authenticators may run before or after the JWT authenticators. The specific position of JWT authenticators in relation to other authenticators is neither defined nor stable across releases. Since each JWT authenticator must have a unique issuer URL, at most one JWT authenticator will attempt to cryptographically validate the token.</p> <p>The minimum valid JWT payload must contain the following claims: {<br/>"iss": "https://issuer.example.com", "aud": ["audience"], "exp": 1234567890,<br/>"&lt;username claim&gt;": "username" }</p> |

## AuthorizationConfiguration

| Field                | Description              |
|----------------------|--------------------------|
| apiVersion<br>string | apiserver.k8s.io/v1beta1 |

| Field                                                                      | Description                                                                                                                                                         |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kind<br>string                                                             | AuthorizationConfiguration                                                                                                                                          |
| authorizers <b>[Required]</b><br><a href="#">[]AuthorizerConfiguration</a> | Authorizers is an ordered list of authorizers to authorize requests against. This is similar to the --authorization-modes kube-apiserver flag Must be at least one. |

## EgressSelectorConfiguration

EgressSelectorConfiguration provides versioned configuration for egress selector clients.

| Field                                                                   | Description                                                                  |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------|
| apiVersion<br>string                                                    | apiserver.k8s.io/v1beta1                                                     |
| kind<br>string                                                          | EgressSelectorConfiguration                                                  |
| egressSelections <b>[Required]</b><br><a href="#">[]EgressSelection</a> | connectionServices contains a list of egress selection client configurations |

## TracingConfiguration

TracingConfiguration provides versioned configuration for tracing clients.

| Field                                                                          | Description                                                                                                                   |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                           | apiserver.k8s.io/v1beta1                                                                                                      |
| kind<br>string                                                                 | TracingConfiguration                                                                                                          |
| TracingConfiguration <b>[Required]</b><br><a href="#">TracingConfiguration</a> | (Members of TracingConfiguration are embedded into this type.)<br><br>Embed the component config tracing configuration struct |

## AudienceMatchPolicyType

(Alias of string)

Appears in:

- [JWTAuthenticator](#)

ClaimMappings provides the configuration for claim mapping

| Field                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| username <b>[Required]</b><br><a href="#">PrefixedClaimOrExpression</a> | <p>username represents an option for the username attribute. The claim's value must be a singular string. Same as the --oidc-username-claim and --oidc-username-prefix flags. If username.expression is set, the expression must produce a string value. If username.expression uses 'claims.email', then 'claims.email_verified' must be used in username.expression or extra[*].valueExpression or claimValidationRules[*].expression. An example claim validation rule expression that matches the validation automatically applied when username.claim is set to 'email' is 'claims.?email_verified.orValue(true)'.</p> <p>In the flag based approach, the --oidc-username-claim and --oidc-username-prefix are optional. If --oidc-username-claim is not set, the default value is "sub". For the authentication config, there is no defaulting for claim or prefix. The claim and prefix must be set explicitly. For claim, if --oidc-username-claim was not set with legacy flag approach, configure username.claim="sub" in the authentication config. For prefix: (1) --oidc-username-prefix="-", no</p> |

| Field                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                     | prefix was added to the username. For the same behavior using authentication config, set username.prefix="" (2) --oidc-username-prefix="" and --oidc-username-claim != "email", prefix was "<value of --oidc-issuer-url>#". For the same behavior using authentication config, set username.prefix="<value of issuer.url>#" (3) --oidc-username-prefix="<value>". For the same behavior using authentication config, set username.prefix="<value>"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| groups<br><a href="#">PrefixedClaimOrExpression</a> | groups represents an option for the groups attribute. The claim's value must be a string or string array claim. If groups.claim is set, the prefix must be specified (and can be the empty string). If groups.expression is set, the expression must produce a string or string array value. "", [], and null values are treated as the group mapping not being present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| uid<br><a href="#">ClaimOrExpression</a>            | uid represents an option for the uid attribute. Claim must be a singular string claim. If uid.expression is set, the expression must produce a string value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| extra<br><a href="#">[]ExtraMapping</a>             | <p>extra represents an option for the extra attribute. expression must produce a string or string array value. If the value is empty, the extra mapping will not be present.</p> <p>hard-coded extra key/value</p> <ul style="list-style-type: none"> <li>• key: "foo" valueExpression: "'bar'" This will result in an extra attribute - foo: ["bar"]</li> </ul> <p>hard-coded key, value copying claim value</p> <ul style="list-style-type: none"> <li>• key: "foo" valueExpression: "claims.some_claim" This will result in an extra attribute - foo: [value of some_claim]</li> </ul> <p>hard-coded key, value derived from claim value</p> <ul style="list-style-type: none"> <li>• key: "admin" valueExpression: '(has(claims.is_admin) &amp;&amp; claims.is_admin) ? "true":""' This will result in:</li> <li>• if is_admin claim is present and true, extra attribute - admin: ["true"]</li> <li>• if is_admin claim is present and false or is_admin claim is not present, no extra attribute will be added</li> </ul> |

## ClaimOrExpression

Appears in:

- [ClaimMappings](#)

ClaimOrExpression provides the configuration for a single claim or expression.

| Field                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| claim<br>string      | claim is the JWT claim to use. Either claim or expression must be set. Mutually exclusive with expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| expression<br>string | <p>expression represents the expression which will be evaluated by CEL.</p> <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"><li>'claims' is a map of claim names to claim values. | message<br>string | message customizes the returned error message when expression returns false. message is a literal string. Mutually exclusive with claim and requiredValue.                                      |

## Connection

Appears in:

- [EgressSelection](#)

Connection provides the configuration for a single egress selection client.

| Field                                                       | Description                                                                                                                                         |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| proxyProtocol<br>[Required]<br><a href="#">ProtocolType</a> | Protocol is the protocol used to connect from client to the konnectivity server.                                                                    |
| transport<br><a href="#">Transport</a>                      | Transport defines the transport configurations we use to dial to the konnectivity server. This is required if ProxyProtocol is HTTPConnect or GRPC. |

## EgressSelection

Appears in:

- [EgressSelectorConfiguration](#)

EgressSelection provides the configuration for a single egress selection client.

| Field                                                  | Description                                                                                                                                                                                   |
|--------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name<br>[Required]<br>string                           | name is the name of the egress selection. Currently supported values are "controlplane", "master", "etcd" and "cluster" The "master" egress selector is deprecated in favor of "controlplane" |
| connection<br>[Required]<br><a href="#">Connection</a> | connection is the exact information used to configure the egress selection                                                                                                                    |

# ExtraMapping

Appears in:

- [ClaimMappings](#)

ExtraMapping provides the configuration for a single extra mapping.

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key <b>[Required]</b><br>string             | key is a string to use as the extra attribute key. key must be a domain-prefix path (e.g. example.org/foo). All characters before the first "/" must be a valid subdomain as defined by RFC 1123. All characters trailing the first "/" must be valid HTTP Path characters as defined by RFC 3986. key must be lowercase. Required to be unique.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| valueExpression <b>[Required]</b><br>string | <p>valueExpression is a CEL expression to extract extra attribute value. valueExpression must produce a string or string array value. "", [], and null values are treated as the extra mapping not being present. Empty string values contained within a string array are filtered out.</p> <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"><li>• 'claims' is a map of claim names to claim values. For example, a variable named 'sub' can be accessed as 'claims.sub'. Nested claims can be accessed using dot notation, e.g. 'claims.foo.bar'.</li></ul> <p>Documentation on CEL: <a href="https://kubernetes.io/docs/reference/using-api/cel/">https://kubernetes.io/docs/reference/using-api/cel/</a></p> |

# Issuer

Appears in:

- [JWTAuthenticator](#)

Issuer provides the configuration for an external provider's specific settings.

| Field                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| url <b>[Required]</b><br>string | url points to the issuer URL in a format https://url or https://url/path. This must match the "iss" claim in the presented JWT, and the issuer returned from discovery. Same value as the --oidc-issuer-url flag. Discovery information is fetched from "{url}/.well-known/openid-configuration" unless overridden by discoveryURL. Required to be unique across all JWT authenticators. Note that egress selection configuration is not used for this network connection. |
| discoveryURL<br>string          | discoveryURL, if specified, overrides the URL used to fetch discovery information instead of using "{url}/.well-known/openid-                                                                                                                                                                                                                                                                                                                                              |

| Field                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                             | <p>configuration". The exact value specified is used, so <code>"/.well-known/openid-configuration"</code> must be included in <code>discoveryURL</code> if needed.</p> <p>The "issuer" field in the fetched discovery information must match the "issuer.url" field in the <code>AuthenticationConfiguration</code> and will be used to validate the "iss" claim in the presented JWT. This is for scenarios where the well-known and jwks endpoints are hosted at a different location than the issuer (such as locally in the cluster).</p> <p>Example: A discovery url that is exposed using kubernetes service 'oidc' in namespace 'oidc-namespace' and discovery information is available at <code>"/.well-known/openid-configuration"</code>. <code>discoveryURL</code>: <code>"https://oidc.oidc-namespace/.well-known/openid-configuration"</code> <code>certificateAuthority</code> is used to verify the TLS connection and the hostname on the leaf certificate must be set to <code>'oidc.oidc-namespace'</code>.</p> <pre>curl https://oidc.oidc-namespace/.well-known/openid-configuration (.discoveryURL field) { issuer: "https://oidc.example.com" (.url field) }</pre> <p><code>discoveryURL</code> must be different from <code>url</code>. Required to be unique across all JWT authenticators. Note that egress selection configuration is not used for this network connection.</p> |
| <code>certificateAuthority</code><br>string                                 | <code>certificateAuthority</code> contains PEM-encoded certificate authority certificates used to validate the connection when fetching discovery information. If unset, the system verifier is used. Same value as the content of the file referenced by the <code>--oidc-ca-file</code> flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>audiences</code> <b>[Required]</b><br>[]string                        | <code>audiences</code> is the set of acceptable audiences the JWT must be issued to. At least one of the entries must match the "aud" claim in presented JWTs. Same value as the <code>--oidc-client-id</code> flag (though this field supports an array). Required to be non-empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>audienceMatchPolicy</code><br><a href="#">AudienceMatchPolicyType</a> | <p><code>audienceMatchPolicy</code> defines how the "audiences" field is used to match the "aud" claim in the presented JWT. Allowed values are:</p> <ol style="list-style-type: none"> <li>1. "MatchAny" when multiple audiences are specified and</li> <li>2. empty (or unset) or "MatchAny" when a single audience is specified.</li> </ol> <ul style="list-style-type: none"> <li>• MatchAny: the "aud" claim in the presented JWT must match at least one of the entries in the "audiences" field. For example, if "audiences" is <code>["foo", "bar"]</code>, the "aud" claim in the presented JWT must contain either "foo" or "bar" (and may contain both).</li> <li>• "": The match policy can be empty (or unset) when a single audience is specified in the "audiences" field. The "aud" claim</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Field | Description                                                                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <p>in the presented JWT must contain the single audience (and may contain others).</p> <p>For more nuanced audience validation, use <code>claimValidationRules</code>. example: <code>claimValidationRule[].expression: 'sets.equivalent(claims.aud, ["bar", "foo", "baz"])</code> to require an exact match.</p> |

## JWTAuthenticator

Appears in:

- [AuthenticationConfiguration](#)

JWTAuthenticator provides the configuration for a single JWT authenticator.

| Field                                                                 | Description                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>issuer [Required]</b><br><a href="#">Issuer</a>                    | issuer contains the basic OIDC provider connection options.                                                                                                                                                                                                                                                                                                        |
| <b>claimValidationRules []</b><br><a href="#">ClaimValidationRule</a> | claimValidationRules are rules that are applied to validate token claims to authenticate users.                                                                                                                                                                                                                                                                    |
| <b>claimMappings [Required]</b><br><a href="#">ClaimMappings</a>      | claimMappings points claims of a token to be treated as user attributes.                                                                                                                                                                                                                                                                                           |
| <b>userValidationRules []</b><br><a href="#">UserValidationRule</a>   | userValidationRules are rules that are applied to final user before completing authentication. These allow invariants to be applied to incoming identities such as preventing the use of the system: prefix that is commonly used by Kubernetes components. The validation rules are logically ANDed together and must all return true for the validation to pass. |

## PrefixedClaimOrExpression

Appears in:

- [ClaimMappings](#)

PrefixedClaimOrExpression provides the configuration for a single prefixed claim or expression.

| Field         | Description                                                        |
|---------------|--------------------------------------------------------------------|
| claim string  | claim is the JWT claim to use. Mutually exclusive with expression. |
| prefix string |                                                                    |

| Field                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | prefix is prepended to claim's value to prevent clashes with existing names. prefix needs to be set if claim is set and can be the empty string. Mutually exclusive with expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| expression<br>string | <p>expression represents the expression which will be evaluated by CEL.</p> <p>CEL expressions have access to the contents of the token claims, organized into CEL variable:</p> <ul style="list-style-type: none"> <li>'claims' is a map of claim names to claim values. For example, a variable named 'sub' can be accessed as 'claims.sub'. Nested claims can be accessed using dot notation, e.g. 'claims.foo.bar'.</li> </ul> <p>Documentation on CEL: <a href="https://kubernetes.io/docs/reference/using-api/cel/">https://kubernetes.io/docs/reference/using-api/cel/</a></p> <p>Mutually exclusive with claim and prefix.</p> |

## ProtocolType

(Alias of string)

Appears in:

- [Connection](#)

ProtocolType is a set of valid values for Connection.ProtocolType

## TCPTransport

Appears in:

- [Transport](#)

TCPTransport provides the information to connect to konnectivity server via TCP

| Field                                  | Description                                                                                                      |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------|
| url<br>[Required]<br>string            | URL is the location of the konnectivity server to connect to. As an example it might be "https://127.0.0.1:8131" |
| tlsConfig<br><a href="#">TLSConfig</a> | TLSConfig is the config needed to use TLS when connecting to konnectivity server                                 |

## TLSConfig

Appears in:

- [TCPTransport](#)

TLSConfig provides the authentication information to connect to konnectivity server Only used with TCPTransport

| Field                | Description                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| caBundle<br>string   | caBundle is the file location of the CA to be used to determine trust with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// If absent while TCPTransport.URL is prefixed with https://, default to system trust roots. |
| clientKey<br>string  | clientKey is the file location of the client key to be used in mtls handshakes with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// Must be configured if TCPTransport.URL is prefixed with https://                  |
| clientCert<br>string | clientCert is the file location of the client certificate to be used in mtls handshakes with the konnectivity server. Must be absent/empty if TCPTransport.URL is prefixed with http:// Must be configured if TCPTransport.URL is prefixed with https://         |

## Transport

Appears in:

- [Connection](#)

Transport defines the transport configurations we use to dial to the konnectivity server

| Field                               | Description                                                                                                                                                                                               |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcp<br><a href="#">TCPTransport</a> | TCP is the TCP configuration for communicating with the konnectivity server via TCP ProxyProtocol of GRPC is not supported with TCP transport at the moment Requires at least one of TCP or UDS to be set |
| uds<br><a href="#">UDSTransport</a> | UDS is the UDS configuration for communicating with the konnectivity server via UDS Requires at least one of TCP or UDS to be set                                                                         |

## UDSTransport

Appears in:

- [Transport](#)

UDSTransport provides the information to connect to konnectivity server via UDS

| Field                           | Description                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| udsName<br>[Required]<br>string | UDSName is the name of the unix domain socket to connect to konnectivity server This does not use a unix:// prefix. (Eg: /etc/srv/kubernetes/konnectivity-server/konnectivity-server.socket) |

## UserValidationRule

Appears in:

- [JWTAuthenticator](#)

UserValidationRule provides the configuration for a single user info validation rule.

# kube-controller-manager Configuration (v1alpha1)

## Resource Types

- [CloudControllerManagerConfiguration](#)
- [LeaderMigrationConfiguration](#)
- [KubeControllerManagerConfiguration](#)

## NodeControllerConfiguration

Appears in:

- [CloudControllerManagerConfiguration](#)

NodeControllerConfiguration contains elements describing NodeController.

| Field                                      | Description                                                                   |
|--------------------------------------------|-------------------------------------------------------------------------------|
| ConcurrentNodeSyncs<br>[Required]<br>int32 | ConcurrentNodeSyncs is the number of workers concurrently synchronizing nodes |

## ServiceControllerConfiguration

Appears in:

- [CloudControllerManagerConfiguration](#)
- [KubeControllerManagerConfiguration](#)

ServiceControllerConfiguration contains elements describing ServiceController.

| Field                                         | Description                                                                                                                                                                  |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentServiceSyncs<br>[Required]<br>int32 | concurrentServiceSyncs is the number of services that are allowed to sync concurrently. Larger number = more responsive service management, but more CPU (and network) load. |

## CloudControllerManagerConfiguration

CloudControllerManagerConfiguration contains elements describing cloud-controller manager.

| Field                | Description                                   |
|----------------------|-----------------------------------------------|

| Generic <b>[Required]</b><br><a href="#">GenericControllerManagerConfiguration</a>    | Generic holds configuration for a generic controller-manager                                                                               |
| KubeCloudShared <b>[Required]</b><br><a href="#">KubeCloudSharedConfiguration</a>     | KubeCloudSharedConfiguration holds configuration for shared related features both in cloud controller manager and kube-controller manager. |
| NodeController <b>[Required]</b><br><a href="#">NodeControllerConfiguration</a>       | NodeController holds configuration for node controller related features.                                                                   |
| ServiceController <b>[Required]</b><br><a href="#">ServiceControllerConfiguration</a> | ServiceControllerConfiguration holds configuration for ServiceController related features.                                                 |
| NodeStatusUpdateFrequency <b>[Required]</b><br><a href="#">meta/v1.Duration</a>       | NodeStatusUpdateFrequency is the frequency at which the controller updates nodes' status                                                   |
| Webhook <b>[Required]</b><br><a href="#">WebhookConfiguration</a>                     | Webhook is the configuration for cloud-controller-manager hosted webhooks                                                                  |

## CloudProviderConfiguration

Appears in:

- [KubeCloudSharedConfiguration](#)

CloudProviderConfiguration contains basically elements about cloud provider.

| Field                                       | Description                                                           |
|---------------------------------------------|-----------------------------------------------------------------------|
| Name <b>[Required]</b><br>string            | Name is the provider for cloud services.                              |
| CloudConfigFile <b>[Required]</b><br>string | cloudConfigFile is the path to the cloud provider configuration file. |

## KubeCloudSharedConfiguration

Appears in:

- [CloudControllerManagerConfiguration](#)

## [KubeControllerManagerConfiguration](#)

KubeCloudSharedConfiguration contains elements shared by both kube-controller manager and cloud-controller manager, but not genericconfig.

| Field                                                                           | Description                                                                                                                                                                               |
|---------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CloudProvider <b>[Required]</b><br><a href="#">CloudProviderConfiguration</a>   | CloudProviderConfiguration holds configuration for CloudProvider related features.                                                                                                        |
| ExternalCloudVolumePlugin <b>[Required]</b><br>string                           | externalCloudVolumePlugin specifies the plugin to use when cloudProvider is "external". It is currently used by the in repo cloud providers to handle node and volume control in the KCM. |
| UseServiceAccountCredentials <b>[Required]</b><br>bool                          | useServiceAccountCredentials indicates whether controllers should be run with individual service account credentials.                                                                     |
| AllowUntaggedCloud <b>[Required]</b><br>bool                                    | run with untagged cloud instances                                                                                                                                                         |
| RouteReconciliationPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | routeReconciliationPeriod is the period for reconciling routes created for Nodes by cloud provider..                                                                                      |
| NodeMonitorPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>         | nodeMonitorPeriod is the period for syncing NodeStatus in NodeController.                                                                                                                 |
| ClusterName <b>[Required]</b><br>string                                         | clusterName is the instance prefix for the cluster.                                                                                                                                       |
| ClusterCIDR <b>[Required]</b><br>string                                         | clusterCIDR is CIDR Range for Pods in cluster.                                                                                                                                            |
| AllocateNodeCIDRs <b>[Required]</b><br>bool                                     | AllocateNodeCIDRs enables CIDRs for Pods to be allocated and, if ConfigureCloudRoutes is true, to be set on the cloud provider.                                                           |
| CIDRAllocatorType <b>[Required]</b><br>string                                   | CIDRAllocatorType determines what kind of pod CIDR allocator will be used.                                                                                                                |
| ConfigureCloudRoutes <b>[Required]</b><br>bool                                  | configureCloudRoutes enables CIDRs allocated with allocateNodeCIDRs to be configured on the cloud provider.                                                                               |
| NodeSyncPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>            | nodeSyncPeriod is the period for syncing nodes from cloudprovider. Longer periods will result in fewer calls to                                                                           |

| Field | Description                                                     |
|-------|-----------------------------------------------------------------|
|       | cloud provider, but may delay addition of new nodes to cluster. |

## WebhookConfiguration

Appears in:

- [CloudControllerManagerConfiguration](#)

WebhookConfiguration contains configuration related to cloud-controller-manager hosted webhooks

| Field                                       | Description                                                                                                                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Webhooks<br>[ <b>Required</b> ]<br>[]string | Webhooks is the list of webhooks to enable or disable '*' means "all enabled by default webhooks" 'foo' means "enable 'foo'" '-foo' means "disable 'foo'" first item for a particular name wins |

## LeaderMigrationConfiguration

Appears in:

- [GenericControllerManagerConfiguration](#)

LeaderMigrationConfiguration provides versioned configuration for all migrating leader locks.

| Field                                                                                    | Description                                                                                                  |
|------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                                     | controllermanager.config.k8s.io/v1alpha1                                                                     |
| kind<br>string                                                                           | LeaderMigrationConfiguration                                                                                 |
| leaderName [ <b>Required</b> ]<br>string                                                 | LeaderName is the name of the leader election resource that protects the migration E.g. 1-20-KCM-to-1-21-CCM |
| resourceLock [ <b>Required</b> ]<br>string                                               | ResourceLock indicates the resource object type that will be used to lock Should be "leases" or "endpoints"  |
| controllerLeaders [ <b>Required</b> ]<br><a href="#">[]ControllerLeaderConfiguration</a> | ControllerLeaders contains a list of migrating leader lock configurations                                    |

## ControllerLeaderConfiguration

Appears in:

- [LeaderMigrationConfiguration](#)

ControllerLeaderConfiguration provides the configuration for a migrating leader lock.

| Field                             | Description                                                                                                                                                                                                                                   |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name<br>[Required]<br>string      | Name is the name of the controller being migrated E.g. service-controller, route-controller, cloud-node-controller, etc                                                                                                                       |
| component<br>[Required]<br>string | Component is the name of the component in which the controller should be running. E.g. kube-controller-manager, cloud-controller-manager, etc Or '*' meaning the controller can be run under any component that participates in the migration |

## GenericControllerManagerConfiguration

Appears in:

- [CloudControllerManagerConfiguration](#)
- [KubeControllerManagerConfiguration](#)

GenericControllerManagerConfiguration holds configuration for a generic controller-manager.

| Field                                                                        | Description                                                                                                                                      |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Port [Required]<br>int32                                                     | port is the port that the controller-manager's http service runs on.                                                                             |
| Address [Required]<br>string                                                 | address is the IP address to serve on (set to 0.0.0.0 for all interfaces).                                                                       |
| MinResyncPeriod [Required]<br><a href="#">meta/v1.Duration</a>               | minResyncPeriod is the resync period in reflectors; will be random between minResyncPeriod and 2*minResyncPeriod.                                |
| ClientConnection [Required]<br><a href="#">ClientConnectionConfiguration</a> | ClientConnection specifies the kubeconfig file and client connection settings for the proxy server to use when communicating with the apiserver. |
| ControllerStartInterval<br>[Required]<br><a href="#">meta/v1.Duration</a>    | How long to wait between starting controller managers                                                                                            |

| Field                                                                               | Description                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LeaderElection [ <b>Required</b> ]<br><a href="#">LeaderElectionConfiguration</a>   | leaderElection defines the configuration of leader election client.                                                                                                                                      |
| Controllers [ <b>Required</b> ]<br>[]string                                         | Controllers is the list of controllers to enable or disable '*' means "all enabled by default controllers" 'foo' means "enable 'foo'" '-foo' means "disable 'foo'" first item for a particular name wins |
| Debugging [ <b>Required</b> ]<br><a href="#">DebuggingConfiguration</a>             | DebuggingConfiguration holds configuration for Debugging related features.                                                                                                                               |
| LeaderMigrationEnabled [ <b>Required</b> ]<br>bool                                  | LeaderMigrationEnabled indicates whether Leader Migration should be enabled for the controller manager.                                                                                                  |
| LeaderMigration [ <b>Required</b> ]<br><a href="#">LeaderMigrationConfiguration</a> | LeaderMigration holds the configuration for Leader Migration.                                                                                                                                            |

## KubeControllerManagerConfiguration

KubeControllerManagerConfiguration contains elements describing kube-controller manager.

| Field                                                                                             | Description                                                                                                                            |
|---------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                                              | kubecontrollermanager.config.k8s.io/v1alpha1                                                                                           |
| kind<br>string                                                                                    | KubeControllerManagerConfiguration                                                                                                     |
| Generic [ <b>Required</b> ]<br><a href="#">GenericControllerManagerConfiguration</a>              | Generic holds configuration for a generic controller manager                                                                           |
| KubeCloudShared [ <b>Required</b> ]<br><a href="#">KubeCloudSharedConfiguration</a>               | KubeCloudSharedConfiguration holds configuration shared related features both in cloud controller manager and kube-controller manager. |
| AttachDetachController [ <b>Required</b> ]<br><a href="#">AttachDetachControllerConfiguration</a> | AttachDetachControllerConfiguration holds configuration for AttachDetachController related features.                                   |
| CSRSigningController [ <b>Required</b> ]<br><a href="#">CSRSigningControllerConfiguration</a>     | CSRSigningControllerConfiguration holds configuration for CSRSigningController related features.                                       |

| Field                                                                                                                 | Description                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| DaemonSetController [ <b>Required</b> ]<br><a href="#">DaemonSetControllerConfiguration</a>                           | DaemonSetControllerConfiguration holds configuration for DaemonSetController related features.                           |
| DeploymentController [ <b>Required</b> ]<br><a href="#">DeploymentControllerConfiguration</a>                         | DeploymentControllerConfiguration holds configuration for DeploymentController related features.                         |
| StatefulSetController [ <b>Required</b> ]<br><a href="#">StatefulSetControllerConfiguration</a>                       | StatefulSetControllerConfiguration holds configuration for StatefulSetController related features.                       |
| DeprecatedController [ <b>Required</b> ]<br><a href="#">DeprecatedControllerConfiguration</a>                         | DeprecatedControllerConfiguration holds configuration for some deprecated features.                                      |
| EndpointController [ <b>Required</b> ]<br><a href="#">EndpointControllerConfiguration</a>                             | EndpointControllerConfiguration holds configuration for EndpointController related features.                             |
| EndpointSliceController [ <b>Required</b> ]<br><a href="#">EndpointSliceControllerConfiguration</a>                   | EndpointSliceControllerConfiguration holds configuration for EndpointSliceController related features.                   |
| EndpointSliceMirroringController [ <b>Required</b> ]<br><a href="#">EndpointSliceMirroringControllerConfiguration</a> | EndpointSliceMirroringControllerConfiguration holds configuration for EndpointSliceMirroringController related features. |
| EphemeralVolumeController [ <b>Required</b> ]<br><a href="#">EphemeralVolumeControllerConfiguration</a>               | EphemeralVolumeControllerConfiguration holds configuration for EphemeralVolumeController related features.               |
| GarbageCollectorController [ <b>Required</b> ]<br><a href="#">GarbageCollectorControllerConfiguration</a>             | GarbageCollectorControllerConfiguration holds configuration for GarbageCollectorController related features.             |
| HPAController [ <b>Required</b> ]<br><a href="#">HPAControllerConfiguration</a>                                       | HPAControllerConfiguration holds configuration for HPAController related features.                                       |
| JobController [ <b>Required</b> ]<br><a href="#">JobControllerConfiguration</a>                                       | JobControllerConfiguration holds configuration for JobController related features.                                       |
| CronJobController [ <b>Required</b> ]<br><a href="#">CronJobControllerConfiguration</a>                               | CronJobControllerConfiguration holds configuration for CronJobController related features.                               |

| Field                                                                                                                 | Description                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| LegacySATokenCleaner [ <b>Required</b> ]<br><a href="#">LegacySATokenCleanerConfiguration</a>                         | LegacySATokenCleanerConfiguration holds configuration for LegacySATokenCleaner related features.                         |
| NamespaceController [ <b>Required</b> ]<br><a href="#">NamespaceControllerConfiguration</a>                           | NamespaceControllerConfiguration holds configuration for NamespaceController related features.                           |
| NodeIPAMController [ <b>Required</b> ]<br><a href="#">NodeIPAMControllerConfiguration</a>                             | NodeIPAMControllerConfiguration holds configuration for NodeIPAMController related features.                             |
| NodeLifecycleController [ <b>Required</b> ]<br><a href="#">NodeLifecycleControllerConfiguration</a>                   | NodeLifecycleControllerConfiguration holds configuration for NodeLifecycleController related features.                   |
| PersistentVolumeBinderController [ <b>Required</b> ]<br><a href="#">PersistentVolumeBinderControllerConfiguration</a> | PersistentVolumeBinderControllerConfiguration holds configuration for PersistentVolumeBinderController related features. |
| PodGCController [ <b>Required</b> ]<br><a href="#">PodGCControllerConfiguration</a>                                   | PodGCControllerConfiguration holds configuration for PodGCController related features.                                   |
| ReplicaSetController [ <b>Required</b> ]<br><a href="#">ReplicaSetControllerConfiguration</a>                         | ReplicaSetControllerConfiguration holds configuration for ReplicaSet related features.                                   |
| ReplicationController [ <b>Required</b> ]<br><a href="#">ReplicationControllerConfiguration</a>                       | ReplicationControllerConfiguration holds configuration for ReplicationController related features.                       |
| ResourceQuotaController [ <b>Required</b> ]<br><a href="#">ResourceQuotaControllerConfiguration</a>                   | ResourceQuotaControllerConfiguration holds configuration for ResourceQuotaController related features.                   |
| SAController [ <b>Required</b> ]<br><a href="#">SAControllerConfiguration</a>                                         | SAControllerConfiguration holds configuration for ServiceAccountController related features.                             |
| ServiceController [ <b>Required</b> ]<br><a href="#">ServiceControllerConfiguration</a>                               | ServiceControllerConfiguration holds configuration for ServiceController related features.                               |
| TTLAfterFinishedController [ <b>Required</b> ]<br><a href="#">TTLAfterFinishedControllerConfiguration</a>             | TTLAfterFinishedControllerConfiguration holds configuration for TTLAfterFinishedController related features.             |

| Field                                                                                                                                 | Description                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| ValidatingAdmissionPolicyStatusController <b>[Required]</b><br><a href="#">ValidatingAdmissionPolicyStatusControllerConfiguration</a> | ValidatingAdmissionPolicyStatusControllerConfiguration holds configuration for ValidatingAdmissionPolicyStatusController related features. |

## AttachDetachControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

AttachDetachControllerConfiguration contains elements describing AttachDetachController.

| Field                                                                          | Description                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DisableAttachDetachReconcilerSync <b>[Required]</b><br>bool                    | Reconciler runs a periodic loop to reconcile the desired state of the with the actual state of the world by triggering attach detach operations. This flag enables or disables reconcile. Is false by default, and thus enabled. |
| ReconcilerSyncLoopPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | ReconcilerSyncLoopPeriod is the amount of time the reconciler sync states loop wait between successive executions. Is set to 60 sec by default.                                                                                  |
| disableForceDetachOnTimeout <b>[Required]</b><br>bool                          | DisableForceDetachOnTimeout disables force detach when the maximum unmount time is exceeded. Is false by default, and thus force detach on unmount is enabled.                                                                   |

## CSRSigningConfiguration

Appears in:

- [CSRSigningControllerConfiguration](#)

CSRSigningConfiguration holds information about a particular CSR signer

| Field                                | Description                                                                                          |
|--------------------------------------|------------------------------------------------------------------------------------------------------|
| CertFile <b>[Required]</b><br>string | certFile is the filename containing a PEM-encoded X509 CA certificate used to issue certificates     |
| KeyFile <b>[Required]</b><br>string  | keyFile is the filename containing a PEM-encoded RSA or ECDSA private key used to issue certificates |

## CSRSigningControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

CSRSigningControllerConfiguration contains elements describing CSRSigningController.

| Field                                                                                               | Description                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ClusterSigningCertFile <b>[Required]</b><br>string                                                  | clusterSigningCertFile is the filename containing a PEM-encoded X509 CA certificate used to issue cluster-scoped certificates                                        |
| ClusterSigningKeyFile <b>[Required]</b><br>string                                                   | clusterSigningKeyFile is the filename containing a PEM-encoded RSA or ECDSA private key used to issue cluster-scoped certificates                                    |
| KubeletServingSignerConfiguration <b>[Required]</b><br><a href="#">CSRSigningConfiguration</a>      | kubeletServingSignerConfiguration holds the certificate and key used to issue certificates for the kubernetes.io/kubelet-serving signer                              |
| KubeletClientSignerConfiguration <b>[Required]</b><br><a href="#">CSRSigningConfiguration</a>       | kubeletClientSignerConfiguration holds the certificate and key used to issue certificates for the kubernetes.io/kube-apiserver-client-kubelet                        |
| KubeAPIServerClientSignerConfiguration <b>[Required]</b><br><a href="#">CSRSigningConfiguration</a> | kubeAPIServerClientSignerConfiguration holds the certificate and key used to issue certificates for the kubernetes.io/kube-apiserver-client                          |
| LegacyUnknownSignerConfiguration <b>[Required]</b><br><a href="#">CSRSigningConfiguration</a>       | legacyUnknownSignerConfiguration holds the certificate and key used to issue certificates for the kubernetes.io/legacy-unknown                                       |
| ClusterSigningDuration <b>[Required]</b><br><a href="#">meta/v1.Duration</a>                        | clusterSigningDuration is the max length of duration signed certificates will be given. Individual CSRs may request shorter certs by setting spec.expirationSeconds. |

## CronJobControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

CronJobControllerConfiguration contains elements describing CronJobController.

| Field                                                | Description                                                                                                                                                       |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentCronJobSyncs<br><b>[Required]</b><br>int32 | concurrentCronJobSyncs is the number of job objects that are allowed to sync concurrently. Larger number = more responsive jobs, but more CPU (and network) load. |

## DaemonSetControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

DaemonSetControllerConfiguration contains elements describing DaemonSetController.

| Field                                                  | Description                                                                                                                                                                    |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentDaemonSetSyncs<br><b>[Required]</b><br>int32 | concurrentDaemonSetSyncs is the number of daemonset objects that are allowed to sync concurrently. Larger number = more responsive daemonset, but more CPU (and network) load. |

## DeploymentControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

DeploymentControllerConfiguration contains elements describing DeploymentController.

| Field                                                   | Description                                                                                                                                                                        |
|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentDeploymentSyncs<br><b>[Required]</b><br>int32 | concurrentDeploymentSyncs is the number of deployment objects that are allowed to sync concurrently. Larger number = more responsive deployments, but more CPU (and network) load. |

## DeprecatedControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

DeprecatedControllerConfiguration contains elements be deprecated.

# EndpointControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

EndpointControllerConfiguration contains elements describing EndpointController.

| Field                                                                               | Description                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentEndpointSyncs<br><b>[Required]</b><br>int32                               | concurrentEndpointSyncs is the number of endpoint syncing operations that will be done concurrently. Larger number = faster endpoint updating, but more CPU (and network) load.                                                                  |
| EndpointUpdatesBatchPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | EndpointUpdatesBatchPeriod describes the length of endpoint updates batching period. Processing of pod changes will be delayed by this duration to join them with potential upcoming updates and reduce the overall number of endpoints updates. |

# EndpointSliceControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

EndpointSliceControllerConfiguration contains elements describing EndpointSliceController.

| Field                                                                               | Description                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentServiceEndpointSyncs<br><b>[Required]</b><br>int32                        | concurrentServiceEndpointSyncs is the number of service endpoint syncing operations that will be done concurrently. Larger number = faster endpoint slice updating, but more CPU (and network) load.                                             |
| MaxEndpointsPerSlice <b>[Required]</b><br>int32                                     | maxEndpointsPerSlice is the maximum number of endpoints that will be added to an EndpointSlice. More endpoints per slice will result in fewer and larger endpoint slices, but larger resources.                                                  |
| EndpointUpdatesBatchPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | EndpointUpdatesBatchPeriod describes the length of endpoint updates batching period. Processing of pod changes will be delayed by this duration to join them with potential upcoming updates and reduce the overall number of endpoints updates. |

# EndpointSliceMirroringControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

EndpointSliceMirroringControllerConfiguration contains elements describing EndpointSliceMirroringController.

| Field                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MirroringConcurrentServiceEndpointSyncs<br><b>[Required]</b><br>int32                        | mirroringConcurrentServiceEndpointSyncs is the number of service endpoint syncing operations that will be done concurrently. Larger number = faster endpoint slice updating, but more CPU (and network) load.                                                                                                                                                                                                     |
| MirroringMaxEndpointsPerSubset<br><b>[Required]</b><br>int32                                 | mirroringMaxEndpointsPerSubset is the maximum number of endpoints that will be mirrored to an EndpointSlice for an EndpointSubset.                                                                                                                                                                                                                                                                                |
| MirroringEndpointUpdatesBatchPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | mirroringEndpointUpdatesBatchPeriod can be used to batch EndpointSlice updates. All updates triggered by EndpointSlice changes will be delayed by up to 'mirroringEndpointUpdatesBatchPeriod'. If other addresses in the same Endpoints resource change in that period, they will be batched to a single EndpointSlice update. Default 0 value means that each Endpoints update triggers an EndpointSlice update. |

# EphemeralVolumeControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

EphemeralVolumeControllerConfiguration contains elements describing EphemeralVolumeController.

| Field                                                        | Description                                                                                                                                                                                                  |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentEphemeralVolumeSyncs<br><b>[Required]</b><br>int32 | ConcurrentEphemeralVolumeSyncseSyncs is the number of ephemeral volume syncing operations that will be done concurrently. Larger number = faster ephemeral volume updating, but more CPU (and network) load. |

# GarbageCollectorControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

GarbageCollectorControllerConfiguration contains elements describing GarbageCollectorController.

| Field                                                               | Description                                                                                                                                                          |
|---------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EnableGarbageCollector<br>[Required]<br>bool                        | enables the generic garbage collector. MUST be synced with the corresponding flag of the kube-apiserver. WARNING: the generic garbage collector is an alpha feature. |
| ConcurrentGCSyncs<br>[Required]<br>int32                            | concurrentGCSyncs is the number of garbage collector workers that are allowed to sync concurrently.                                                                  |
| GCIgnoredResources<br>[Required]<br><a href="#">[]GroupResource</a> | gcIgnoredResources is the list of GroupResources that garbage collection should ignore.                                                                              |

# GroupResource

Appears in:

- [GarbageCollectorControllerConfiguration](#)

GroupResource describes an group resource.

| Field                         | Description                                            |
|-------------------------------|--------------------------------------------------------|
| Group [Required]<br>string    | group is the group portion of the GroupResource.       |
| Resource [Required]<br>string | resource is the resource portion of the GroupResource. |

# HPAControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

HPAControllerConfiguration contains elements describing HPAController.

| Field                                                      | Description                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| ConcurrentHorizontalPodAutoscalerSyncs [Required]<br>int32 | ConcurrentHorizontalPodAutoscalerSyncs is the number of HPA objects that are allowed to sync |

| Field                                                                                                     | Description                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                           | concurrently. Larger number = more responsive HPA processing, but more CPU (and network) load.                                                                                                                                                                                                |
| HorizontalPodAutoscalerSyncPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>                   | HorizontalPodAutoscalerSyncPeriod is the period for syncing the number of pods in horizontal pod autoscaler.                                                                                                                                                                                  |
| HorizontalPodAutoscalerUpscaleForbiddenWindow <b>[Required]</b><br><a href="#">meta/v1.Duration</a>       | HorizontalPodAutoscalerUpscaleForbiddenWindow is a period after which next upscale allowed.                                                                                                                                                                                                   |
| HorizontalPodAutoscalerDownscaleStabilizationWindow <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | HorizontalPodAutoscalerDownscaleStabilizationWindow is a period for which autoscaler will look backward and not scale down below any recommendation it made during that period.                                                                                                               |
| HorizontalPodAutoscalerDownscaleForbiddenWindow <b>[Required]</b><br><a href="#">meta/v1.Duration</a>     | HorizontalPodAutoscalerDownscaleForbiddenWindow is a period after which next downscale allowed.                                                                                                                                                                                               |
| HorizontalPodAutoscalerTolerance <b>[Required]</b><br>float64                                             | HorizontalPodAutoscalerTolerance is the tolerance when resource usage suggests upscaling/downscaling.                                                                                                                                                                                         |
| HorizontalPodAutoscalerCPUInitializationPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>      | HorizontalPodAutoscalerCPUInitializationPeriod is a period after pod start when CPU samples might be skipped.                                                                                                                                                                                 |
| HorizontalPodAutoscalerInitialReadinessDelay <b>[Required]</b><br><a href="#">meta/v1.Duration</a>        | HorizontalPodAutoscalerInitialReadinessDelay is a period after pod start during which readiness changes are treated as readiness being set for the first time. The effect of this is that HPA will disregard CPU samples from unready pods that had last readiness change during that period. |

## JobControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

JobControllerConfiguration contains elements describing JobController.

| Field                                         | Description |
|-----------------------------------------------|-------------|
| ConcurrentJobSyncs <b>[Required]</b><br>int32 |             |

| Field | Description                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | concurrentJobSyncs is the number of job objects that are allowed to sync concurrently. Larger number = more responsive jobs, but more CPU (and network) load. |

## LegacySATokenCleanerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

LegacySATokenCleanerConfiguration contains elements describing LegacySATokenCleaner

| Field                                                           | Description                                                                                                                   |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| CleanUpPeriod<br>[Required]<br><a href="#">meta/v1.Duration</a> | CleanUpPeriod is the period of time since the last usage of an auto-generated service account token before it can be deleted. |

## NamespaceControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

NamespaceControllerConfiguration contains elements describing NamespaceController.

| Field                                                                 | Description                                                                                        |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| NamespaceSyncPeriod<br>[Required]<br><a href="#">meta/v1.Duration</a> | namespaceSyncPeriod is the period for syncing namespace life-cycle updates.                        |
| ConcurrentNamespaceSyncs<br>[Required]<br>int32                       | concurrentNamespaceSyncs is the number of namespace objects that are allowed to sync concurrently. |

## NodeIPAMControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

NodeIPAMControllerConfiguration contains elements describing NodeIpamController.

| Field                            | Description                                        |
|----------------------------------|----------------------------------------------------|
| ServiceCIDR [Required]<br>string | serviceCIDR is CIDR Range for Services in cluster. |

| Field                                               | Description                                                                                                                                                           |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SecondaryServiceCIDR<br><b>[Required]</b><br>string | secondaryServiceCIDR is CIDR Range for Services in cluster. This is used in dual stack clusters. SecondaryServiceCIDR must be of different IP family than ServiceCIDR |
| NodeCIDRMaskSize<br><b>[Required]</b><br>int32      | NodeCIDRMaskSize is the mask size for node cidr in cluster.                                                                                                           |
| NodeCIDRMaskSizeIPv4<br><b>[Required]</b><br>int32  | NodeCIDRMaskSizeIPv4 is the mask size for node cidr in dual-stack cluster.                                                                                            |
| NodeCIDRMaskSizeIPv6<br><b>[Required]</b><br>int32  | NodeCIDRMaskSizeIPv6 is the mask size for node cidr in dual-stack cluster.                                                                                            |

## NodeLifecycleControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

NodeLifecycleControllerConfiguration contains elements describing NodeLifecycleController.

| Field                                                                           | Description                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NodeEvictionRate<br><b>[Required]</b><br>float32                                | nodeEvictionRate is the number of nodes per second on which pods are deleted in case of node failure when a zone is healthy                                                                                                                                        |
| SecondaryNodeEvictionRate<br><b>[Required]</b><br>float32                       | secondaryNodeEvictionRate is the number of nodes per second on which pods are deleted in case of node failure when a zone is unhealthy                                                                                                                             |
| NodeStartupGracePeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | nodeStartupGracePeriod is the amount of time which we allow starting a node to be unresponsive before marking it unhealthy.                                                                                                                                        |
| NodeMonitorGracePeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | nodeMonitorGracePeriod is the amount of time which we allow a running node to be unresponsive before marking it unhealthy. Must be N times more than kubelet's nodeStatusUpdateFrequency, where N means number of retries allowed for kubelet to post node status. |
| PodEvictionTimeout<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>     | podEvictionTimeout is the grace period for deleting pods on failed nodes.                                                                                                                                                                                          |

| Field                                            | Description                                                                                                                                                            |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LargeClusterSizeThreshold<br>[Required]<br>int32 | secondaryNodeEvictionRate is implicitly overridden to 0 for clusters smaller than or equal to largeClusterSizeThreshold                                                |
| UnhealthyZoneThreshold<br>[Required]<br>float32  | Zone is treated as unhealthy in nodeEvictionRate and secondaryNodeEvictionRate when at least unhealthyZoneThreshold (no less than 3) of Nodes in the zone are NotReady |

## PersistentVolumeBinderControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

PersistentVolumeBinderControllerConfiguration contains elements describing PersistentVolumeBinderController.

| Field                                                                     | Description                                                                                                                 |
|---------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| PVClaimBinderSyncPeriod<br>[Required]<br><a href="#">meta/v1.Duration</a> | pvClaimBinderSyncPeriod is the period for syncing persistent volumes and persistent volume claims.                          |
| VolumeConfiguration [Required]<br><a href="#">VolumeConfiguration</a>     | volumeConfiguration holds configuration for volume related features.                                                        |
| VolumeHostCIDRDenylist<br>[Required]<br>[]string                          | DEPRECATED: VolumeHostCIDRDenylist is a list of CIDRs that should not be reachable by the controller from plugins.          |
| VolumeHostAllowLocalLoopback<br>[Required]<br>bool                        | DEPRECATED: VolumeHostAllowLocalLoopback indicates if local loopback hosts (127.0.0.1, etc) should be allowed from plugins. |

## PersistentVolumeRecyclerConfiguration

Appears in:

- [VolumeConfiguration](#)

PersistentVolumeRecyclerConfiguration contains elements describing persistent volume plugins.

| Field                                                   | Description                                                                                                                                                                                                       |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MaximumRetry <b>[Required]</b><br>int32                 | maximumRetry is number of retries the PV recycler will execute on failure to recycle PV.                                                                                                                          |
| MinimumTimeoutNFS <b>[Required]</b><br>int32            | minimumTimeoutNFS is the minimum ActiveDeadlineSeconds to use for an NFS Recycler pod.                                                                                                                            |
| PodTemplateFilePathNFS <b>[Required]</b><br>string      | podTemplateFilePathNFS is the file path to a pod definition used as a template for NFS persistent volume recycling                                                                                                |
| IncrementTimeoutNFS <b>[Required]</b><br>int32          | incrementTimeoutNFS is the increment of time added per Gi to ActiveDeadlineSeconds for an NFS scrubber pod.                                                                                                       |
| PodTemplateFilePathHostPath <b>[Required]</b><br>string | podTemplateFilePathHostPath is the file path to a pod definition used as a template for HostPath persistent volume recycling. This is for development and testing only and will not work in a multi-node cluster. |
| MinimumTimeoutHostPath <b>[Required]</b><br>int32       | minimumTimeoutHostPath is the minimum ActiveDeadlineSeconds to use for a HostPath Recycler pod. This is for development and testing only and will not work in a multi-node cluster.                               |
| IncrementTimeoutHostPath <b>[Required]</b><br>int32     | incrementTimeoutHostPath is the increment of time added per Gi to ActiveDeadlineSeconds for a HostPath scrubber pod. This is for development and testing only and will not work in a multi-node cluster.          |

## PodGCControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

PodGCControllerConfiguration contains elements describing PodGCController.

| Field                                               | Description                                                                                                                                                                                                      |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TerminatedPodGCThreshold <b>[Required]</b><br>int32 | terminatedPodGCThreshold is the number of terminated pods that can exist before the terminated pod garbage collector starts deleting terminated pods. If <= 0, the terminated pod garbage collector is disabled. |

## ReplicaSetControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

ReplicaSetControllerConfiguration contains elements describing ReplicaSetController.

| Field                                           | Description                                                                                                                                                                 |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentRSSyncs<br><b>[Required]</b><br>int32 | concurrentRSSyncs is the number of replica sets that are allowed to sync concurrently. Larger number = more responsive replica management, but more CPU (and network) load. |

## ReplicationControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

ReplicationControllerConfiguration contains elements describing ReplicationController.

| Field                                           | Description                                                                                                                                                                            |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentRCSyncs<br><b>[Required]</b><br>int32 | concurrentRCSyncs is the number of replication controllers that are allowed to sync concurrently. Larger number = more responsive replica management, but more CPU (and network) load. |

## ResourceQuotaControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

ResourceQuotaControllerConfiguration contains elements describing ResourceQuotaController.

| Field                                                                            | Description                                                                                                                                                                             |
|----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ResourceQuotaSyncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | resourceQuotaSyncPeriod is the period for syncing quota usage status in the system.                                                                                                     |
| ConcurrentResourceQuotaSyncs<br><b>[Required]</b><br>int32                       | concurrentResourceQuotaSyncs is the number of resource quotas that are allowed to sync concurrently. Larger number = more responsive quota management, but more CPU (and network) load. |

## SAControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

SAControllerConfiguration contains elements describing ServiceAccountController.

| Field                                         | Description                                                                                                                                  |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| ServiceAccountKeyFile<br>[Required]<br>string | serviceAccountKeyFile is the filename containing a PEM-encoded private RSA key used to sign service account tokens.                          |
| ConcurrentSATokenSyncs<br>[Required]<br>int32 | concurrentSATokenSyncs is the number of service account token syncing operations that will be done concurrently.                             |
| RootCAFile [Required]<br>string               | rootCAFile is the root certificate authority will be included in service account's token secret. This must be a valid PEM-encoded CA bundle. |

## StatefulSetControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

StatefulSetControllerConfiguration contains elements describing StatefulSetController.

| Field                                             | Description                                                                                                                                                                           |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentStatefulSetSyncs<br>[Required]<br>int32 | concurrentStatefulSetSyncs is the number of statefulset objects that are allowed to sync concurrently. Larger number = more responsive statefulsets, but more CPU (and network) load. |

## TTLAfterFinishedControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

TTLAfterFinishedControllerConfiguration contains elements describing TTLAfterFinishedController.

| Field                                     | Description                                                                                                     |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| ConcurrentTTLSyncs<br>[Required]<br>int32 | concurrentTTLSyncs is the number of TTL-after-finished collector workers that are allowed to sync concurrently. |

# ValidatingAdmissionPolicyStatusControllerConfiguration

Appears in:

- [KubeControllerManagerConfiguration](#)

ValidatingAdmissionPolicyStatusControllerConfiguration contains elements describing ValidatingAdmissionPolicyStatusController.

| Field                                               | Description                                                                                                                                                                                  |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ConcurrentPolicySyncs<br><b>[Required]</b><br>int32 | ConcurrentPolicySyncs is the number of policy objects that are allowed to sync concurrently. Larger number = quicker type checking, but more CPU (and network) load. The default value is 5. |

## VolumeConfiguration

Appears in:

- [PersistentVolumeBinderControllerConfiguration](#)

VolumeConfiguration contains *all* enumerated flags meant to configure all volume plugins. From this config, the controller-manager binary will create many instances of volume.VolumeConfig, each containing only the configuration needed for that plugin which are then passed to the appropriate plugin. The ControllerManager binary is the only part of the code which knows what plugins are supported and which flags correspond to each plugin.

| Field                                                                                                               | Description                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EnableHostPathProvisioning<br><b>[Required]</b><br>bool                                                             | enableHostPathProvisioning enables HostPath PV provisioning when running without a cloud provider. This allows testing and development of provisioning features. HostPath provisioning is not supported in any way, won't work in a multi-node cluster, and should not be used for anything other than testing or development. |
| EnableDynamicProvisioning<br><b>[Required]</b><br>bool                                                              | enableDynamicProvisioning enables the provisioning of volumes when running within an environment that supports dynamic provisioning. Defaults to true.                                                                                                                                                                         |
| PersistentVolumeRecyclerConfiguration<br><b>[Required]</b><br><a href="#">PersistentVolumeRecyclerConfiguration</a> | persistentVolumeRecyclerConfiguration holds configuration for persistent volume plugins.                                                                                                                                                                                                                                       |

| Field                                           | Description                                                                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| FlexVolumePluginDir <b>[Required]</b><br>string | volumePluginDir is the full path of the directory in which the flex volume plugin should search for additional third party volume plugins |

# kube-proxy Configuration (v1alpha1)

## Resource Types

- [KubeProxyConfiguration](#)

## ClientConnectionConfiguration

Appears in:

- [KubeProxyConfiguration](#)
- [KubeSchedulerConfiguration](#)
- [GenericControllerManagerConfiguration](#)

ClientConnectionConfiguration contains details for constructing a client.

| Field                                             | Description                                                                                                                                                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kubeconfig<br><b>[Required]</b><br>string         | kubeconfig is the path to a KubeConfig file.                                                                                                                                                                                     |
| acceptContentTypes<br><b>[Required]</b><br>string | acceptContentTypes defines the Accept header sent by clients when connecting to a server, overriding the default value of 'application/json'. This field will control all connections to the server used by a particular client. |
| contentType<br><b>[Required]</b><br>string        | contentType is the content type used when sending data to the server from this client.                                                                                                                                           |
| qps <b>[Required]</b><br>float32                  | qps controls the number of queries per second allowed for this connection.                                                                                                                                                       |
| burst <b>[Required]</b><br>int32                  | burst allows extra queries to accumulate when a client is exceeding its rate.                                                                                                                                                    |

# DebuggingConfiguration

Appears in:

- [KubeSchedulerConfiguration](#)
- [GenericControllerManagerConfiguration](#)

DebuggingConfiguration holds configuration for Debugging related features.

| Field                                               | Description                                                                       |
|-----------------------------------------------------|-----------------------------------------------------------------------------------|
| enableProfiling <b>[Required]</b><br>bool           | enableProfiling enables profiling via web interface<br>host:port/debug/pprof/     |
| enableContentionProfiling <b>[Required]</b><br>bool | enableContentionProfiling enables block profiling, if<br>enableProfiling is true. |

# LeaderElectionConfiguration

Appears in:

- [KubeSchedulerConfiguration](#)
- [GenericControllerManagerConfiguration](#)

LeaderElectionConfiguration defines the configuration of leader election clients for components that can run with leader election enabled.

| Field                                                               | Description                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| leaderElect <b>[Required]</b><br>bool                               | leaderElect enables a leader election client to gain leadership before<br>executing the main loop. Enable this when running replicated<br>components for high availability.                                                                                                                                                                                             |
| leaseDuration <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | leaseDuration is the duration that non-leader candidates will wait after<br>observing a leadership renewal until attempting to acquire leadership of<br>a led but unrenewed leader slot. This is effectively the maximum<br>duration that a leader can be stopped before it is replaced by another<br>candidate. This is only applicable if leader election is enabled. |
| renewDeadline <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | renewDeadline is the interval between attempts by the acting master to<br>renew a leadership slot before it stops leading. This must be less than or<br>equal to the lease duration. This is only applicable if leader election is<br>enabled.                                                                                                                          |

| Field                                                                | Description                                                                                                                                                            |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| retryPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | retryPeriod is the duration the clients should wait between attempting acquisition and renewal of a leadership. This is only applicable if leader election is enabled. |
| resourceLock<br><b>[Required]</b><br>string                          | resourceLock indicates the resource object type that will be used to lock during leader election cycles.                                                               |
| resourceName<br><b>[Required]</b><br>string                          | resourceName indicates the name of resource object that will be used to lock during leader election cycles.                                                            |
| resourceNamespace<br><b>[Required]</b><br>string                     | resourceName indicates the namespace of resource object that will be used to lock during leader election cycles.                                                       |

## KubeProxyConfiguration

KubeProxyConfiguration contains everything necessary to configure the Kubernetes proxy server.

| Field                                                                               | Description                                                                                                                                                                   |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                                | kubeproxy.config.k8s.io/v1alpha1                                                                                                                                              |
| kind<br>string                                                                      | KubeProxyConfiguration                                                                                                                                                        |
| featureGates <b>[Required]</b><br>map[string]bool                                   | featureGates is a map of feature names to bools that enable or disable alpha/experimental features.                                                                           |
| clientConnection <b>[Required]</b><br><a href="#">ClientConnectionConfiguration</a> | clientConnection specifies the kubeconfig file and client connection settings for the proxy server to use when communicating with the apiserver.                              |
| logging <b>[Required]</b><br><a href="#">LoggingConfiguration</a>                   | logging specifies the options of logging. Refer to <a href="#">Logs Options</a> for more information.                                                                         |
| hostnameOverride <b>[Required]</b><br>string                                        | hostnameOverride, if non-empty, will be used as the name of the Node that kube-proxy is running on. If unset, the node name is assumed to be the same as the node's hostname. |
| bindAddress <b>[Required]</b><br>string                                             | bindAddress can be used to override kube-proxy's idea of what its node's primary IP is. Note that the name is a                                                               |

| Field                                                                          | Description                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                | historical artifact, and kube-proxy does not actually bind any sockets to this IP.                                                                                                                                                                                 |
| healthzBindAddress <b>[Required]</b><br>string                                 | healthzBindAddress is the IP address and port for the health check server to serve on, defaulting to "0.0.0.0:10256" (if bindAddress is unset or IPv4), or "[::]:10256" (if bindAddress is IPv6).                                                                  |
| metricsBindAddress <b>[Required]</b><br>string                                 | metricsBindAddress is the IP address and port for the metrics server to serve on, defaulting to "127.0.0.1:10249" (if bindAddress is unset or IPv4), or "[::1]:10249" (if bindAddress is IPv6). (Set to "0.0.0.0:10249" / "[::]:10249" to bind on all interfaces.) |
| bindAddressHardFail <b>[Required]</b><br>bool                                  | bindAddressHardFail, if true, tells kube-proxy to treat failure to bind to a port as fatal and exit                                                                                                                                                                |
| enableProfiling <b>[Required]</b><br>bool                                      | enableProfiling enables profiling via web interface on / debug/pprof handler. Profiling handlers will be handled by metrics server.                                                                                                                                |
| showHiddenMetricsForVersion <b>[Required]</b><br>string                        | showHiddenMetricsForVersion is the version for which you want to show hidden metrics.                                                                                                                                                                              |
| mode <b>[Required]</b><br><a href="#">ProxyMode</a>                            | mode specifies which proxy mode to use.                                                                                                                                                                                                                            |
| iptables <b>[Required]</b><br><a href="#">KubeProxyIPTablesConfiguration</a>   | iptables contains iptables-related configuration options.                                                                                                                                                                                                          |
| ipvs <b>[Required]</b><br><a href="#">KubeProxyIPVSConfiguration</a>           | ipvs contains ipvs-related configuration options.                                                                                                                                                                                                                  |
| nftables <b>[Required]</b><br><a href="#">KubeProxyNFTablesConfiguration</a>   | nftables contains nftables-related configuration options.                                                                                                                                                                                                          |
| winkernel <b>[Required]</b><br><a href="#">KubeProxyWinkernelConfiguration</a> | winkernel contains winkernel-related configuration options.                                                                                                                                                                                                        |
| detectLocalMode <b>[Required]</b><br><a href="#">LocalMode</a>                 | detectLocalMode determines mode to use for detecting local traffic, defaults to LocalModeClusterCIDR                                                                                                                                                               |
| detectLocal <b>[Required]</b><br><a href="#">DetectLocalConfiguration</a>      | detectLocal contains optional configuration settings related to DetectLocalMode.                                                                                                                                                                                   |

| Field                                                                          | Description                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clusterCIDR <b>[Required]</b><br>string                                        | clusterCIDR is the CIDR range of the pods in the cluster. (For dual-stack clusters, this can be a comma-separated dual-stack pair of CIDR ranges.). When DetectLocalMode is set to LocalModeClusterCIDR, kube-proxy will consider traffic to be local if its source IP is in this range. (Otherwise it is not used.) |
| nodePortAddresses <b>[Required]</b><br>[]string                                | nodePortAddresses is a list of CIDR ranges that contain valid node IPs. If set, connections to NodePort services will only be accepted on node IPs in one of the indicated ranges. If unset, NodePort connections will be accepted on all local IPs.                                                                 |
| oomScoreAdj <b>[Required]</b><br>int32                                         | oomScoreAdj is the oom-score-adj value for kube-proxy process. Values must be within the range [-1000, 1000]                                                                                                                                                                                                         |
| conntrack <b>[Required]</b><br><a href="#">KubeProxyConntrackConfiguration</a> | conntrack contains conntrack-related configuration options.                                                                                                                                                                                                                                                          |
| configSyncPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>         | configSyncPeriod is how often configuration from the apiserver is refreshed. Must be greater than 0.                                                                                                                                                                                                                 |
| portRange <b>[Required]</b><br>string                                          | portRange was previously used to configure the userspace proxy, but is now unused.                                                                                                                                                                                                                                   |

## DetectLocalConfiguration

Appears in:

- [KubeProxyConfiguration](#)

DetectLocalConfiguration contains optional settings related to DetectLocalMode option

| Field                                           | Description                                                                                                                                                                                                                        |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bridgeInterface <b>[Required]</b><br>string     | bridgeInterface is a bridge interface name. When DetectLocalMode is set to LocalModeBridgeInterface, kube-proxy will consider traffic to be local if it originates from this bridge.                                               |
| interfaceNamePrefix <b>[Required]</b><br>string | interfaceNamePrefix is an interface name prefix. When DetectLocalMode is set to LocalModeInterfaceNamePrefix, kube-proxy will consider traffic to be local if it originates from any interface whose name begins with this prefix. |

# KubeProxyConntrackConfiguration

Appears in:

- [KubeProxyConfiguration](#)

KubeProxyConntrackConfiguration contains conntrack settings for the Kubernetes proxy server.

| Field                                                                       | Description                                                                                                                                                                    |
|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxPerCore <b>[Required]</b><br>int32                                       | maxPerCore is the maximum number of NAT connections to track per CPU core (0 to leave the limit as-is and ignore min).                                                         |
| min <b>[Required]</b><br>int32                                              | min is the minimum value of connect-tracking records to allocate, regardless of maxPerCore (set maxPerCore=0 to leave the limit as-is).                                        |
| tcpEstablishedTimeout <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | tcpEstablishedTimeout is how long an idle TCP connection will be kept open (e.g. '2s'). Must be greater than 0 to set.                                                         |
| tcpCloseWaitTimeout <b>[Required]</b><br><a href="#">meta/v1.Duration</a>   | tcpCloseWaitTimeout is how long an idle conntrack entry in CLOSE_WAIT state will remain in the conntrack table. (e.g. '60s'). Must be greater than 0 to set.                   |
| tcpBeLiberal <b>[Required]</b><br>bool                                      | tcpBeLiberal, if true, kube-proxy will configure conntrack to run in liberal mode for TCP connections and packets with out-of-window sequence numbers won't be marked INVALID. |
| udpTimeout <b>[Required]</b><br><a href="#">meta/v1.Duration</a>            | udpTimeout is how long an idle UDP conntrack entry in UNREPLIED state will remain in the conntrack table (e.g. '30s'). Must be greater than 0 to set.                          |
| udpStreamTimeout <b>[Required]</b><br><a href="#">meta/v1.Duration</a>      | udpStreamTimeout is how long an idle UDP conntrack entry in ASSURED state will remain in the conntrack table (e.g. '300s'). Must be greater than 0 to set.                     |

# KubeProxyIPTablesConfiguration

Appears in:

- [KubeProxyConfiguration](#)

KubeProxyIPTablesConfiguration contains iptables-related configuration details for the Kubernetes proxy server.

| Field                                                                  | Description                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| masqueradeBit<br><b>[Required]</b><br>int32                            | masqueradeBit is the bit of the iptables fwmark space to use for SNAT if using the iptables or ipvs proxy mode. Values must be within the range [0, 31].                                                                                                       |
| masqueradeAll<br><b>[Required]</b><br>bool                             | masqueradeAll tells kube-proxy to SNAT all traffic sent to Service cluster IPs, when using the iptables or ipvs proxy mode. This may be required with some CNI plugins.                                                                                        |
| localhostNodePorts<br><b>[Required]</b><br>bool                        | localhostNodePorts, if false, tells kube-proxy to disable the legacy behavior of allowing NodePort services to be accessed via localhost. (Applies only to iptables mode and IPv4; localhost NodePorts are never allowed with other proxy modes or with IPv6.) |
| syncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>    | syncPeriod is an interval (e.g. '5s', '1m', '2h22m') indicating how frequently various re-synchronizing and cleanup operations are performed. Must be greater than 0.                                                                                          |
| minSyncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | minSyncPeriod is the minimum period between iptables rule resyncs (e.g. '5s', '1m', '2h22m'). A value of 0 means every Service or EndpointSlice change will result in an immediate iptables resync.                                                            |

## KubeProxyIPVSConfiguration

Appears in:

- [KubeProxyConfiguration](#)

KubeProxyIPVSConfiguration contains ipvs-related configuration details for the Kubernetes proxy server.

| Field                                                                  | Description                                                                                                                                                                                 |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| syncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>    | syncPeriod is an interval (e.g. '5s', '1m', '2h22m') indicating how frequently various re-synchronizing and cleanup operations are performed. Must be greater than 0.                       |
| minSyncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | minSyncPeriod is the minimum period between IPVS rule resyncs (e.g. '5s', '1m', '2h22m'). A value of 0 means every Service or EndpointSlice change will result in an immediate IPVS resync. |
| scheduler<br><b>[Required]</b><br>string                               | scheduler is the IPVS scheduler to use                                                                                                                                                      |

| Field                                                                  | Description                                                                                                                                                           |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| excludeCIDRs<br><b>[Required]</b><br>[]string                          | excludeCIDRs is a list of CIDRs which the ipvs proxier should not touch when cleaning up ipvs services.                                                               |
| strictARP<br><b>[Required]</b><br>bool                                 | strictARP configures arp_ignore and arp_announce to avoid answering ARP queries from kube-ipvs0 interface                                                             |
| tcpTimeout<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>    | tcpTimeout is the timeout value used for idle IPVS TCP sessions. The default value is 0, which preserves the current timeout value on the system.                     |
| tcpFinTimeout<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | tcpFinTimeout is the timeout value used for IPVS TCP sessions after receiving a FIN. The default value is 0, which preserves the current timeout value on the system. |
| udpTimeout<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>    | udpTimeout is the timeout value used for IPVS UDP packets. The default value is 0, which preserves the current timeout value on the system.                           |

## KubeProxyNFTablesConfiguration

Appears in:

- [KubeProxyConfiguration](#)

KubeProxyNFTablesConfiguration contains nftables-related configuration details for the Kubernetes proxy server.

| Field                                                                  | Description                                                                                                                                                                                         |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| masqueradeBit<br><b>[Required]</b><br>int32                            | masqueradeBit is the bit of the iptables fwmark space to use for SNAT if using the nftables proxy mode. Values must be within the range [0, 31].                                                    |
| masqueradeAll<br><b>[Required]</b><br>bool                             | masqueradeAll tells kube-proxy to SNAT all traffic sent to Service cluster IPs, when using the nftables mode. This may be required with some CNI plugins.                                           |
| syncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a>    | syncPeriod is an interval (e.g. '5s', '1m', '2h22m') indicating how frequently various re-synchronizing and cleanup operations are performed. Must be greater than 0.                               |
| minSyncPeriod<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | minSyncPeriod is the minimum period between iptables rule resyncs (e.g. '5s', '1m', '2h22m'). A value of 0 means every Service or EndpointSlice change will result in an immediate iptables resync. |

# KubeProxyWinkernelConfiguration

Appears in:

- [KubeProxyConfiguration](#)

KubeProxyWinkernelConfiguration contains Windows/HNS settings for the Kubernetes proxy server.

| Field                                             | Description                                                                                            |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| networkName [ <b>Required</b> ]<br>string         | networkName is the name of the network kube-proxy will use to create endpoints and policies            |
| sourceVip [ <b>Required</b> ]<br>string           | sourceVip is the IP address of the source VIP endpoint used for NAT when loadbalancing                 |
| enableDSR [ <b>Required</b> ]<br>bool             | enableDSR tells kube-proxy whether HNS policies should be created with DSR                             |
| rootHnsEndpointName [ <b>Required</b> ]<br>string | rootHnsEndpointName is the name of hnsendpoint that is attached to l2bridge for root network namespace |
| forwardHealthCheckVip [ <b>Required</b> ]<br>bool | forwardHealthCheckVip forwards service VIP for health check port on Windows                            |

## LocalMode

(Alias of string)

Appears in:

- [KubeProxyConfiguration](#)

LocalMode represents modes to detect local traffic from the node

## ProxyMode

(Alias of string)

Appears in:

- [KubeProxyConfiguration](#)

ProxyMode represents modes used by the Kubernetes proxy server.

Currently, two modes of proxy are available on Linux platforms: 'iptables' and 'ipvs'. One mode of proxy is available on Windows platforms: 'kernelSpace'.

If the proxy mode is unspecified, the best-available proxy mode will be used (currently this is iptables on Linux and kernelSpace on Windows). If the selected proxy mode cannot be used (due to lack of kernel support, missing userspace components, etc) then kube-proxy will exit with an error.

## ClientConnectionConfiguration

Appears in:

- [KubeSchedulerConfiguration](#)

ClientConnectionConfiguration contains details for constructing a client.

| Field                                      | Description                                                                                                                                                                                                                      |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kubeconfig<br>[Required]<br>string         | kubeconfig is the path to a KubeConfig file.                                                                                                                                                                                     |
| acceptContentTypes<br>[Required]<br>string | acceptContentTypes defines the Accept header sent by clients when connecting to a server, overriding the default value of 'application/json'. This field will control all connections to the server used by a particular client. |
| contentType<br>[Required]<br>string        | contentType is the content type used when sending data to the server from this client.                                                                                                                                           |
| qps [Required]<br>float32                  | qps controls the number of queries per second allowed for this connection.                                                                                                                                                       |
| burst [Required]<br>int32                  | burst allows extra queries to accumulate when a client is exceeding its rate.                                                                                                                                                    |

# DebuggingConfiguration

Appears in:

- [KubeSchedulerConfiguration](#)

DebuggingConfiguration holds configuration for Debugging related features.

| Field                                               | Description                                                                       |
|-----------------------------------------------------|-----------------------------------------------------------------------------------|
| enableProfiling <b>[Required]</b><br>bool           | enableProfiling enables profiling via web interface<br>host:port/debug/pprof/     |
| enableContentionProfiling <b>[Required]</b><br>bool | enableContentionProfiling enables block profiling, if<br>enableProfiling is true. |

# LeaderElectionConfiguration

Appears in:

- [KubeSchedulerConfiguration](#)

LeaderElectionConfiguration defines the configuration of leader election clients for components that can run with leader election enabled.

| Field                                                               | Description                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| leaderElect <b>[Required]</b><br>bool                               | leaderElect enables a leader election client to gain leadership before<br>executing the main loop. Enable this when running replicated<br>components for high availability.                                                                                                                                                                                             |
| leaseDuration <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | leaseDuration is the duration that non-leader candidates will wait after<br>observing a leadership renewal until attempting to acquire leadership of<br>a led but unrenewed leader slot. This is effectively the maximum<br>duration that a leader can be stopped before it is replaced by another<br>candidate. This is only applicable if leader election is enabled. |
| renewDeadline <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | renewDeadline is the interval between attempts by the acting master to<br>renew a leadership slot before it stops leading. This must be less than or<br>equal to the lease duration. This is only applicable if leader election is<br>enabled.                                                                                                                          |
| retryPeriod <b>[Required]</b><br><a href="#">meta/v1.Duration</a>   | retryPeriod is the duration the clients should wait between attempting<br>acquisition and renewal of a leadership. This is only applicable if leader<br>election is enabled.                                                                                                                                                                                            |

| Field                                            | Description                                                                                                      |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| resourceLock<br><b>[Required]</b><br>string      | resourceLock indicates the resource object type that will be used to lock during leader election cycles.         |
| resourceName<br><b>[Required]</b><br>string      | resourceName indicates the name of resource object that will be used to lock during leader election cycles.      |
| resourceNamespace<br><b>[Required]</b><br>string | resourceName indicates the namespace of resource object that will be used to lock during leader election cycles. |

## DefaultPreemptionArgs

DefaultPreemptionArgs holds arguments used to configure the DefaultPreemption plugin.

| Field                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                      | kubescheduler.config.k8s.io/v1                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| kind<br>string                                            | DefaultPreemptionArgs                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| minCandidateNodesPercentage<br><b>[Required]</b><br>int32 | MinCandidateNodesPercentage is the minimum number of candidates to shortlist when dry running preemption as a percentage of number of nodes. Must be in the range [0, 100]. Defaults to 10% of the cluster size if unspecified.                                                                                                                                                                                                                                                |
| minCandidateNodesAbsolute<br><b>[Required]</b><br>int32   | MinCandidateNodesAbsolute is the absolute minimum number of candidates to shortlist. The likely number of candidates enumerated for dry running preemption is given by the formula: numCandidates = max(numNodes * minCandidateNodesPercentage, minCandidateNodesAbsolute)<br>We say "likely" because there are other factors such as PDB violations that play a role in the number of candidates shortlisted. Must be at least 0 nodes. Defaults to 100 nodes if unspecified. |

## InterPodAffinityArgs

InterPodAffinityArgs holds arguments used to configure the InterPodAffinity plugin.

| Field                | Description                    |
|----------------------|--------------------------------|
| apiVersion<br>string | kubescheduler.config.k8s.io/v1 |
| kind<br>string       | InterPodAffinityArgs           |

| Field                                                        | Description                                                                                                                                                                                   |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hardPodAffinityWeight <b>[Required]</b><br>int32             | HardPodAffinityWeight is the scoring weight for existing pods with a matching hard affinity to the incoming pod.                                                                              |
| ignorePreferredTermsOfExistingPods <b>[Required]</b><br>bool | IgnorePreferredTermsOfExistingPods configures the scheduler to ignore existing pods' preferred affinity rules when scoring candidate nodes, unless the incoming pod has inter-pod affinities. |

## KubeSchedulerConfiguration

KubeSchedulerConfiguration configures a scheduler

| Field                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                                | kubescheduler.config.k8s.io/v1                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| kind<br>string                                                                      | KubeSchedulerConfiguration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| parallelism <b>[Required]</b><br>int32                                              | Parallelism defines the amount of parallelism in algorithms for scheduling a Pods. Must be greater than 0. Defaults to 16                                                                                                                                                                                                                                                                                                                                                                                   |
| leaderElection <b>[Required]</b><br><a href="#">LeaderElectionConfiguration</a>     | LeaderElection defines the configuration of leader election client.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| clientConnection <b>[Required]</b><br><a href="#">ClientConnectionConfiguration</a> | ClientConnection specifies the kubeconfig file and client connection settings for the proxy server to use when communicating with the apiserver.                                                                                                                                                                                                                                                                                                                                                            |
| DebuggingConfiguration <b>[Required]</b><br><a href="#">DebuggingConfiguration</a>  | (Members of DebuggingConfiguration are embedded into this type.)<br><br>DebuggingConfiguration holds configuration for Debugging related features TODO: We might wanna make this a substruct like Debugging<br>componentbaseconfigv1alpha1.DebuggingConfiguration                                                                                                                                                                                                                                           |
| percentageOfNodesToScore <b>[Required]</b><br>int32                                 | PercentageOfNodesToScore is the percentage of all nodes that once found feasible for running a pod, the scheduler stops its search for more feasible nodes in the cluster. This helps improve scheduler's performance. Scheduler always tries to find at least "minFeasibleNodesToFind" feasible nodes no matter what the value of this flag is. Example: if the cluster size is 500 nodes and the value of this flag is 30, then scheduler stops finding further feasible nodes once it finds 150 feasible |

| Field                                                                | Description                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                      | ones. When the value is 0, default percentage (5%--50% based on the size of the cluster) of the nodes will be scored. It is overridden by profile level PercentageofNodesToScore.                                                                                                                              |
| podInitialBackoffSeconds<br><b>[Required]</b><br>int64               | PodInitialBackoffSeconds is the initial backoff for unschedulable pods. If specified, it must be greater than 0. If this value is null, the default value (1s) will be used.                                                                                                                                   |
| podMaxBackoffSeconds<br><b>[Required]</b><br>int64                   | PodMaxBackoffSeconds is the max backoff for unschedulable pods. If specified, it must be greater than podInitialBackoffSeconds. If this value is null, the default value (10s) will be used.                                                                                                                   |
| profiles <b>[Required]</b><br><a href="#">[]KubeSchedulerProfile</a> | Profiles are scheduling profiles that kube-scheduler supports. Pods can choose to be scheduled under a particular profile by setting its associated scheduler name. Pods that don't specify any scheduler name are scheduled with the "default-scheduler" profile, if present here.                            |
| extenders <b>[Required]</b><br><a href="#">[]Extender</a>            | Extenders are the list of scheduler extenders, each holding the values of how to communicate with the extender. These extenders are shared by all scheduler profiles.                                                                                                                                          |
| delayCacheUntilActive<br><b>[Required]</b><br>bool                   | DelayCacheUntilActive specifies when to start caching. If this is true and leader election is enabled, the scheduler will wait to fill informer caches until it is the leader. Doing so will have slower failover with the benefit of lower memory overhead while waiting to become leader. Defaults to false. |

## NodeAffinityArgs

NodeAffinityArgs holds arguments to configure the NodeAffinity plugin.

| Field                                                 | Description                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                  | kubescheduler.config.k8s.io/v1                                                                                                                                                                                                                                                                                                                                             |
| kind<br>string                                        | NodeAffinityArgs                                                                                                                                                                                                                                                                                                                                                           |
| addedAffinity<br><a href="#">core/v1.NodeAffinity</a> | AddedAffinity is applied to all Pods additionally to the NodeAffinity specified in the PodSpec. That is, Nodes need to satisfy AddedAffinity AND .spec.NodeAffinity. AddedAffinity is empty by default (all Nodes match). When AddedAffinity is used, some Pods with affinity requirements that match a specific Node (such as Daemonset Pods) might remain unschedulable. |

## NodeResourcesBalancedAllocationArgs

NodeResourcesBalancedAllocationArgs holds arguments used to configure NodeResourcesBalancedAllocation plugin.

| Field                                                              | Description                                                                  |
|--------------------------------------------------------------------|------------------------------------------------------------------------------|
| apiVersion<br>string                                               | kubescheduler.config.k8s.io/v1                                               |
| kind<br>string                                                     | NodeResourcesBalancedAllocationArgs                                          |
| resources<br>[ <b>Required</b> ]<br><a href="#">[]ResourceSpec</a> | Resources to be managed, the default is "cpu" and "memory" if not specified. |

## NodeResourcesFitArgs

NodeResourcesFitArgs holds arguments used to configure the NodeResourcesFit plugin.

| Field                                                                     | Description                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                      | kubescheduler.config.k8s.io/v1                                                                                                                                                                                                                                                                                                     |
| kind<br>string                                                            | NodeResourcesFitArgs                                                                                                                                                                                                                                                                                                               |
| ignoredResources<br>[ <b>Required</b> ]<br>[]string                       | IgnoredResources is the list of resources that NodeResources fit filter should ignore. This doesn't apply to scoring.                                                                                                                                                                                                              |
| ignoredResourceGroups<br>[ <b>Required</b> ]<br>[]string                  | IgnoredResourceGroups defines the list of resource groups that NodeResources fit filter should ignore. e.g. if group is ["example.com"], it will ignore all resource names that begin with "example.com", such as "example.com/aaa" and "example.com/bbb". A resource group name can't contain '/'. This doesn't apply to scoring. |
| scoringStrategy<br>[ <b>Required</b> ]<br><a href="#">ScoringStrategy</a> | ScoringStrategy selects the node resource scoring strategy. The default strategy is LeastAllocated with an equal "cpu" and "memory" weight.                                                                                                                                                                                        |

## PodTopologySpreadArgs

PodTopologySpreadArgs holds arguments used to configure the PodTopologySpread plugin.

| Field                | Description                    |
|----------------------|--------------------------------|
| apiVersion<br>string | kubescheduler.config.k8s.io/v1 |
| kind<br>string       | PodTopologySpreadArgs          |

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| defaultConstraints<br><a href="#">[]core/v1.TopologySpreadConstraint</a> | DefaultConstraints defines topology spread constraints to be applied to Pods that don't define any in pod.spec.topologySpreadConstraints. .defaultConstraints[*].labelSelector must be empty, as they are deduced from the Pod's membership to Services, ReplicationControllers, ReplicaSets or StatefulSets. When empty, .defaultingType must be "List". |
| defaultingType<br><a href="#">PodTopologySpreadConstraintsDefaulting</a> | <p>DefaultingType determines how .defaultConstraints are deduced. one of "System" or "List".</p> <ul style="list-style-type: none"> <li>• "System": Use kubernetes defined constraints that spread Pods among Nodes and Zones.</li> <li>• "List": Use constraints defined in .defaultConstraints.</li> </ul> <p>Defaults to "System".</p>                 |

## VolumeBindingArgs

VolumeBindingArgs holds arguments used to configure the VolumeBinding plugin.

| Field                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                             | kubescheduler.config.k8s.io/v1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| kind<br>string                                   | VolumeBindingArgs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| bindTimeoutSeconds<br><b>[Required]</b><br>int64 | BindTimeoutSeconds is the timeout in seconds in volume binding operation. Value must be non-negative integer. The value zero indicates no waiting. If this value is nil, the default value (600) will be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| shape<br><a href="#">[]UtilizationShapePoint</a> | <p>Shape specifies the points defining the score function shape, which is used to score nodes based on the utilization of statically provisioned PVs. The utilization is calculated by dividing the total requested storage of the pod by the total capacity of feasible PVs on each node. Each point contains utilization (ranges from 0 to 100) and its associated score (ranges from 0 to 10). You can turn the priority by specifying different scores for different utilization numbers. The default shape points are:</p> <ol style="list-style-type: none"> <li>1. 0 for 0 utilization</li> <li>2. 10 for 100 utilization</li> </ol> <p>All points must be sorted in increasing order by utilization.</p> |

# Extender

Appears in:

- [KubeSchedulerConfiguration](#)

Extender holds the parameters used to communicate with the extender. If a verb is unspecified/empty, it is assumed that the extender chose not to provide that extension.

| Field                                                             | Description                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| urlPrefix <b>[Required]</b><br>string                             | URLPrefix at which the extender is available                                                                                                                                                                                                                                                   |
| filterVerb <b>[Required]</b><br>string                            | Verb for the filter call, empty if not supported. This verb is appended to the URLPrefix when issuing the filter call to extender.                                                                                                                                                             |
| preemptVerb <b>[Required]</b><br>string                           | Verb for the preempt call, empty if not supported. This verb is appended to the URLPrefix when issuing the preempt call to extender.                                                                                                                                                           |
| prioritizeVerb <b>[Required]</b><br>string                        | Verb for the prioritize call, empty if not supported. This verb is appended to the URLPrefix when issuing the prioritize call to extender.                                                                                                                                                     |
| weight <b>[Required]</b><br>int64                                 | The numeric multiplier for the node scores that the prioritize call generates. The weight should be a positive integer                                                                                                                                                                         |
| bindVerb <b>[Required]</b><br>string                              | Verb for the bind call, empty if not supported. This verb is appended to the URLPrefix when issuing the bind call to extender. If this method is implemented by the extender, it is the extender's responsibility to bind the pod to apiserver. Only one extender can implement this function. |
| enableHTTPS <b>[Required]</b><br>bool                             | EnableHTTPS specifies whether https should be used to communicate with the extender                                                                                                                                                                                                            |
| tlsConfig <b>[Required]</b><br><a href="#">ExtenderTLSConfig</a>  | TLSConfig specifies the transport layer security config                                                                                                                                                                                                                                        |
| httpTimeout <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | HTTPTimeout specifies the timeout duration for a call to the extender. Filter timeout fails the scheduling of the pod. Prioritize timeout is ignored, k8s/other extenders priorities are used to select the node.                                                                              |

| Field                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nodeCacheCapable<br><b>[Required]</b><br>bool                 | NodeCacheCapable specifies that the extender is capable of caching node information, so the scheduler should only send minimal information about the eligible nodes assuming that the extender already cached full details of all nodes in the cluster                                                                                                                                                                                                                                                                        |
| managedResources<br><a href="#">[]ExtenderManagedResource</a> | ManagedResources is a list of extended resources that are managed by this extender. <ul style="list-style-type: none"> <li>• A pod will be sent to the extender on the Filter, Prioritize and Bind (if the extender is the binder) phases iff the pod requests at least one of the extended resources in this list. If empty or unspecified, all pods will be sent to this extender.</li> <li>• If IgnoredByScheduler is set to true for a resource, kube-scheduler will skip checking the resource in predicates.</li> </ul> |
| ignorable <b>[Required]</b><br>bool                           | Ignorable specifies if the extender is ignorable, i.e. scheduling should not fail when the extender returns an error or is not reachable.                                                                                                                                                                                                                                                                                                                                                                                     |

## ExtenderManagedResource

Appears in:

- [Extender](#)

ExtenderManagedResource describes the arguments of extended resources managed by an extender.

| Field                                           | Description                                                                                               |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| name <b>[Required]</b><br>string                | Name is the extended resource name.                                                                       |
| ignoredByScheduler<br><b>[Required]</b><br>bool | IgnoredByScheduler indicates whether kube-scheduler should ignore this resource when applying predicates. |

## ExtenderTLSConfig

Appears in:

- [Extender](#)

ExtenderTLSConfig contains settings to enable TLS with extender

| Field                                     | Description                                                                                                                                                                         |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| insecure<br><b>[Required]</b><br>bool     | Server should be accessed without verifying the TLS certificate. For testing only.                                                                                                  |
| serverName<br><b>[Required]</b><br>string | ServerName is passed to the server for SNI and is used in the client to check server certificates against. If ServerName is empty, the hostname used to contact the server is used. |
| certFile<br><b>[Required]</b><br>string   | Server requires TLS client certificate authentication                                                                                                                               |
| keyFile<br><b>[Required]</b><br>string    | Server requires TLS client certificate authentication                                                                                                                               |
| caFile<br><b>[Required]</b><br>string     | Trusted root certificates for server                                                                                                                                                |
| certData<br><b>[Required]</b><br>[]byte   | CertData holds PEM-encoded bytes (typically read from a client certificate file). CertData takes precedence over CertFile                                                           |
| keyData<br><b>[Required]</b><br>[]byte    | KeyData holds PEM-encoded bytes (typically read from a client certificate key file). KeyData takes precedence over KeyFile                                                          |
| caData<br><b>[Required]</b><br>[]byte     | CAData holds PEM-encoded bytes (typically read from a root certificates bundle). CAData takes precedence over CAFile                                                                |

## KubeSchedulerProfile

Appears in:

- [KubeSchedulerConfiguration](#)

KubeSchedulerProfile is a scheduling profile.

| Field                                                  | Description                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| schedulerName <b>[Required]</b><br>string              | SchedulerName is the name of the scheduler associated to this profile. If SchedulerName matches with the pod's "spec.schedulerName", then the pod is scheduled with this profile.                                                                                                                                         |
| percentageOfNodesToScore<br><b>[Required]</b><br>int32 | PercentageOfNodesToScore is the percentage of all nodes that once found feasible for running a pod, the scheduler stops its search for more feasible nodes in the cluster. This helps improve scheduler's performance. Scheduler always tries to find at least "minFeasibleNodesToFind" feasible nodes no matter what the |

| Field                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                  | value of this flag is. Example: if the cluster size is 500 nodes and the value of this flag is 30, then scheduler stops finding further feasible nodes once it finds 150 feasible ones. When the value is 0, default percentage (5%--50% based on the size of the cluster) of the nodes will be scored. It will override global PercentageOfNodesToScore. If it is empty, global PercentageOfNodesToScore will be used.                                                                                   |
| plugins <b>[Required]</b><br><a href="#">Plugins</a>             | Plugins specify the set of plugins that should be enabled or disabled. Enabled plugins are the ones that should be enabled in addition to the default plugins. Disabled plugins are any of the default plugins that should be disabled. When no enabled or disabled plugin is specified for an extension point, default plugins for that extension point will be used if there is any. If a QueueSort plugin is specified, the same QueueSort Plugin and PluginConfig must be specified for all profiles. |
| pluginConfig <b>[Required]</b><br><a href="#">[]PluginConfig</a> | PluginConfig is an optional set of custom plugin arguments for each plugin. Omitting config args for a plugin is equivalent to using the default config for that plugin.                                                                                                                                                                                                                                                                                                                                  |

## Plugin

Appears in:

- [PluginSet](#)

Plugin specifies a plugin name and its weight when applicable. Weight is used only for Score plugins.

| Field                             | Description                                                       |
|-----------------------------------|-------------------------------------------------------------------|
| name <b>[Required]</b><br>string  | Name defines the name of plugin                                   |
| weight <b>[Required]</b><br>int32 | Weight defines the weight of plugin, only used for Score plugins. |

## PluginConfig

Appears in:

- [KubeSchedulerProfile](#)

PluginConfig specifies arguments that should be passed to a plugin at the time of initialization. A plugin that is invoked at multiple extension points is initialized once. Args can have arbitrary structure. It is up to the plugin to process these Args.

| Field                                                                                                                                     | Description                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| name <b>[Required]</b><br>string                                                                                                          | Name defines the name of plugin being configured                                                                   |
| args <b>[Required]</b><br><a href="https://k8s.io/apimachinery/pkg/runtime.RawExtension">k8s.io/apimachinery/pkg/runtime.RawExtension</a> | Args defines the arguments passed to the plugins at the time of initialization. Args can have arbitrary structure. |

## PluginSet

Appears in:

- [Plugins](#)

PluginSet specifies enabled and disabled plugins for an extension point. If an array is empty, missing, or nil, default plugins at that extension point will be used.

| Field                                                  | Description                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enabled <b>[Required]</b><br><a href="#">[]Plugin</a>  | Enabled specifies plugins that should be enabled in addition to default plugins. If the default plugin is also configured in the scheduler config file, the weight of plugin will be overridden accordingly. These are called after default plugins and in the same order specified here. |
| disabled <b>[Required]</b><br><a href="#">[]Plugin</a> | Disabled specifies default plugins that should be disabled. When all default plugins need to be disabled, an array containing only one "*" should be provided.                                                                                                                            |

## Plugins

Appears in:

- [KubeSchedulerProfile](#)

Plugins include multiple extension points. When specified, the list of plugins for a particular extension point are the only ones enabled. If an extension point is omitted from the config, then the default set of plugins is used for that extension point. Enabled plugins are called in the order specified here, after default plugins. If they need to be invoked before default plugins, default plugins must be disabled and re-enabled here in desired order.

| Field                                                     | Description                                                                                        |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| preEnqueue <b>[Required]</b><br><a href="#">PluginSet</a> | PreEnqueue is a list of plugins that should be invoked before adding pods to the scheduling queue. |
| queueSort <b>[Required]</b><br><a href="#">PluginSet</a>  | QueueSort is a list of plugins that should be invoked when sorting pods in the scheduling queue.   |

| Field                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| preFilter<br>[Required]<br><a href="#">PluginSet</a>  | PreFilter is a list of plugins that should be invoked at "PreFilter" extension point of the scheduling framework.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| filter<br>[Required]<br><a href="#">PluginSet</a>     | Filter is a list of plugins that should be invoked when filtering out nodes that cannot run the Pod.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| postFilter<br>[Required]<br><a href="#">PluginSet</a> | PostFilter is a list of plugins that are invoked after filtering phase, but only when no feasible nodes were found for the pod.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| preScore<br>[Required]<br><a href="#">PluginSet</a>   | PreScore is a list of plugins that are invoked before scoring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| score<br>[Required]<br><a href="#">PluginSet</a>      | Score is a list of plugins that should be invoked when ranking nodes that have passed the filtering phase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| reserve<br>[Required]<br><a href="#">PluginSet</a>    | Reserve is a list of plugins invoked when reserving/unreserving resources after a node is assigned to run the pod.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| permit<br>[Required]<br><a href="#">PluginSet</a>     | Permit is a list of plugins that control binding of a Pod. These plugins can prevent or delay binding of a Pod.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| preBind<br>[Required]<br><a href="#">PluginSet</a>    | PreBind is a list of plugins that should be invoked before a pod is bound.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| bind<br>[Required]<br><a href="#">PluginSet</a>       | Bind is a list of plugins that should be invoked at "Bind" extension point of the scheduling framework. The scheduler call these plugins in order. Scheduler skips the rest of these plugins as soon as one returns success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| postBind<br>[Required]<br><a href="#">PluginSet</a>   | PostBind is a list of plugins that should be invoked after a pod is successfully bound.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| multiPoint<br>[Required]<br><a href="#">PluginSet</a> | <p>MultiPoint is a simplified config section to enable plugins for all valid extension points. Plugins enabled through MultiPoint will automatically register for every individual extension point the plugin has implemented. Disabling a plugin through MultiPoint disables that behavior. The same is true for disabling "*" through MultiPoint (no default plugins will be automatically registered). Plugins can still be disabled through their individual extension points.</p> <p>In terms of precedence, plugin config follows this basic hierarchy</p> <ol style="list-style-type: none"> <li>1. Specific extension points</li> <li>2. Explicitly configured MultiPoint plugins</li> </ol> |

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | 3. The set of default plugins, as MultiPoint plugins This implies that a higher precedence plugin will run first and overwrite any settings within MultiPoint. Explicitly user-configured plugins also take a higher precedence over default plugins. Within this hierarchy, an Enabled setting takes precedence over Disabled. For example, if a plugin is set in both multiPoint.Enabled and multiPoint.Disabled, the plugin will be enabled. Similarly, including multiPoint.Disabled = '*' and multiPoint.Enabled = pluginA will still register that specific plugin through MultiPoint. This follows the same behavior as all other extension point configurations. |

## PodTopologySpreadConstraintsDefaulting

(Alias of string)

Appears in:

- [PodTopologySpreadArgs](#)

PodTopologySpreadConstraintsDefaulting defines how to set default constraints for the PodTopologySpread plugin.

## RequestedToCapacityRatioParam

Appears in:

| Field                     | Description                                                             |
|---------------------------|-------------------------------------------------------------------------|
| score [Required]<br>int32 | Score assigned to given utilization (y axis). Valid values are 0 to 10. |

# kubeadm Configuration (v1beta3)

## Overview

Package v1beta3 defines the v1beta3 version of the kubeadm configuration file format. This version improves on the v1beta2 format by fixing some minor issues and adding a few new fields.

A list of changes since v1beta2:

- The deprecated "ClusterConfiguration.useHyperKubeImage" field has been removed. Kubeadm no longer supports the hyperkube image.
- The "ClusterConfiguration.DNS.Type" field has been removed since CoreDNS is the only supported DNS server type by kubeadm.
- Include "datapolicy" tags on the fields that hold secrets. This would result in the field values to be omitted when API structures are printed with klog.
- Add "InitConfiguration.SkipPhases", "JoinConfiguration.SkipPhases" to allow skipping a list of phases during kubeadm init/join command execution.
- Add "InitConfiguration.NodeRegistration.ImagePullPolicy" and "JoinConfiguration.NodeRegistration.ImagePullPolicy" to allow specifying the images pull policy during kubeadm "init" and "join". The value must be one of "Always", "Never" or "IfNotPresent". "IfNotPresent" is the default, which has been the existing behavior prior to this addition.
- Add "InitConfiguration.Patches.Directory", "JoinConfiguration.Patches.Directory" to allow the user to configure a directory from which to take patches for components deployed by kubeadm.
- Move the BootstrapToken\* API and related utilities out of the "kubeadm" API group to a new group "bootstraptoken". The kubeadm API version v1beta3 no longer contains the BootstrapToken\* structures.

Migration from old kubeadm config versions

- kubeadm v1.15.x and newer can be used to migrate from v1beta1 to v1beta2.
- kubeadm v1.22.x and newer no longer support v1beta1 and older APIs, but can be used to migrate v1beta2 to v1beta3.
- kubeadm v1.27.x and newer no longer support v1beta2 and older APIs,

## Basics

The preferred way to configure kubeadm is to pass an YAML configuration file with the `--config` option. Some of the configuration options defined in the kubeadm config file are also available as command line flags, but only the most common/simple use case are supported with this approach.

A kubeadm config file could contain multiple configuration types separated using three dashes (`---`).

kubeadm supports the following configuration types:

```
apiVersion: kubeadm.k8s.io/v1beta3
kind: InitConfiguration

apiVersion: kubeadm.k8s.io/v1beta3
kind: ClusterConfiguration

apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration

apiVersion: kubeproxy.config.k8s.io/v1alpha1
kind: KubeProxyConfiguration

apiVersion: kubeadm.k8s.io/v1beta3
kind: JoinConfiguration
```

To print the defaults for "init" and "join" actions use the following commands:

```
kubeadm config print init-defaults
kubeadm config print join-defaults
```

The list of configuration types that must be included in a configuration file depends by the action you are performing (init or join) and by the configuration options you are going to use (defaults or advanced customization).

If some configuration types are not provided, or provided only partially, kubeadm will use default values; defaults provided by kubeadm includes also enforcing consistency of values across components when required (e.g. --cluster-cidr flag on controller manager and clusterCIDR on kube-proxy).

Users are always allowed to override default values, with the only exception of a small subset of setting with relevance for security (e.g. enforce authorization-mode Node and RBAC on api server).

If the user provides a configuration types that is not expected for the action you are performing, kubeadm will ignore those types and print a warning.

## Kubeadm init configuration types

When executing kubeadm init with the --config option, the following configuration types could be used: InitConfiguration, ClusterConfiguration, KubeProxyConfiguration, KubeletConfiguration, but only one between InitConfiguration and ClusterConfiguration is mandatory.

```
apiVersion: kubeadm.k8s.io/v1beta3
kind: InitConfiguration
bootstrapTokens:
 ...
nodeRegistration:
 ...
```

The InitConfiguration type should be used to configure runtime settings, that in case of kubeadm init are the configuration of the bootstrap token and all the setting which are specific to the node where kubeadm is executed, including:

- NodeRegistration, that holds fields that relate to registering the new node to the cluster; use it to customize the node name, the CRI socket to use or any other settings that should apply to this node only (e.g. the node ip).
- LocalAPIEndpoint, that represents the endpoint of the instance of the API server to be deployed on this node; use it e.g. to customize the API server advertise address.

```
apiVersion: kubeadm.k8s.io/v1beta3
kind: ClusterConfiguration
networking:
 ...
etcd:
 ...
apiServer:
 extraArgs:
 ...
 extraVolumes:
 ...
...
```

The ClusterConfiguration type should be used to configure cluster-wide settings, including settings for:

- networking that holds configuration for the networking topology of the cluster; use it e.g. to customize Pod subnet or services subnet.
- etcd: use it e.g. to customize the local etcd or to configure the API server for using an external etcd cluster.
- kube-apiserver, kube-scheduler, kube-controller-manager configurations; use it to customize control-plane components by adding customized setting or overriding kubeadm default settings.

```
apiVersion: kubeproxy.config.k8s.io/v1alpha1
kind: KubeProxyConfiguration
...
```

The KubeProxyConfiguration type should be used to change the configuration passed to kube-proxy instances deployed in the cluster. If this object is not provided or provided only partially, kubeadm applies defaults.

See <https://kubernetes.io/docs/reference/command-line-tools-reference/kube-proxy/> or <https://pkg.go.dev/k8s.io/kube-proxy/config/v1alpha1#KubeProxyConfiguration> for kube-proxy official documentation.

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
...
```

The KubeletConfiguration type should be used to change the configurations that will be passed to all kubelet instances deployed in the cluster. If this object is not provided or provided only partially, kubeadm applies defaults.

See <https://kubernetes.io/docs/reference/command-line-tools-reference/kubelet/> or <https://pkg.go.dev/k8s.io/kubelet/config/v1beta1#KubeletConfiguration> for kubelet official documentation.

Here is a fully populated example of a single YAML file containing multiple configuration types to be used during a kubeadm init run.

```
apiVersion: kubeadm.k8s.io/v1beta3
kind: InitConfiguration
bootstrapTokens:
- token: "9a08jv.c0izixklcxtmnze7"

## Kubeadm join configuration types

When executing kubeadm join with the `--config` option, the JoinConfiguration type should be provided.

```
apiVersion: kubeadm.k8s.io/v1beta3
kind: JoinConfiguration
...
```

The JoinConfiguration type should be used to configure runtime settings, that in case of kubeadm join are the discovery method used for accessing the cluster info and all the setting which are specific to the node where kubeadm is executed, including:

- `nodeRegistration`, that holds fields that relate to registering the new node to the cluster; use it to customize the node name, the CRI socket to use or any other settings that should apply to this node only (e.g. the node ip).
- `apiEndpoint`, that represents the endpoint of the instance of the API server to be eventually deployed on this node.

## Resource Types

- [InitConfiguration](#)
- [JoinConfiguration](#)

## BootstrapToken

Appears in:

- [InitConfiguration](#)

BootstrapToken describes one bootstrap token, stored as a Secret in the cluster

| Field                                                             | Description                                                                                                                           |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| token [ <b>Required</b> ]<br><a href="#">BootstrapTokenString</a> | token is used for establishing bidirectional trust between nodes and control-planes. Used for joining nodes in the cluster.           |
| description<br>string                                             | description sets a human-friendly message why this token exists and what it's used for, so other administrators can know its purpose. |

| Field                                   | Description                                                                                                                                                     |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ttl<br><a href="#">meta/v1.Duration</a> | ttl defines the time to live for this token. Defaults to 24h. expires and ttl are mutually exclusive.                                                           |
| expires<br><a href="#">meta/v1.Time</a> | expires specifies the timestamp when this token expires. Defaults to being set dynamically at runtime based on the ttl. expires and ttl are mutually exclusive. |
| usages<br>[]string                      | usages describes the ways in which this token can be used. Can by default be used for establishing bidirectional trust, but that can be changed here.           |
| groups<br>[]string                      | groups specifies the extra groups that this token will authenticate as when/if used for authentication                                                          |

## BootstrapTokenString

Appears in:

- [BootstrapToken](#)

BootstrapTokenString is a token of the format abcdef.abcdef0123456789 that is used for both validation of the practicality of the API server from a joining node's point of view and as an authentication method for the node in the bootstrap phase of "kubeadm join". This token is and should be short-lived.

| Field                  | Description              |
|------------------------|--------------------------|
| - [Required]<br>string | No description provided. |
| - [Required]<br>string | No description provided. |

## ClusterConfiguration

ClusterConfiguration contains cluster-wide configuration for a kubeadm cluster.

| Field                                    | Description                            |
|------------------------------------------|----------------------------------------|
| apiVersion<br>string                     | kubeadm.k8s.io/v1beta3                 |
| kind<br>string                           | ClusterConfiguration                   |
| etcd<br><a href="#">Etcd</a>             | etcd holds the configuration for etcd. |
| networking<br><a href="#">Networking</a> |                                        |

| Field                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## InitConfiguration

InitConfiguration contains a list of elements that is specific "kubeadm init"-only runtime information. kubeadm init-only information. These fields are solely used the first time kubeadm init runs. After that, the information in the fields IS NOT uploaded to the kubeadm-config ConfigMap that is used by kubeadm upgrade for instance. These fields must be empty.

| Field                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| bootstrapTokens<br><a href="#">[]BootstrapToken</a>         | bootstrapTokens is respected at kubeadm init time and describes a set of Bootstrap Tokens to create. This information IS NOT uploaded to the kubeadm cluster configmap, partly because of its sensitive nature                                                                                                                                                                                                                                                                                                                                                                                                                     |
| nodeRegistration<br><a href="#">NodeRegistrationOptions</a> | nodeRegistration holds fields that relate to registering the new control-plane node to the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| localAPIEndpoint<br><a href="#">APIEndpoint</a>             | localAPIEndpoint represents the endpoint of the API server instance that's deployed on this control plane node. In HA setups, this differs from ClusterConfiguration.controlPlaneEndpoint in the sense that controlPlaneEndpoint is the global endpoint for the cluster, which then load-balances the requests to each individual API server. This configuration object lets you customize what IP/DNS name and port the local API server advertises it's accessible on. By default, kubeadm tries to auto-detect the IP of the default interface and use that, but in case that process fails you may set the desired value here. |
| certificateKey<br>string                                    | certificateKey sets the key with which certificates and keys are encrypted prior to being uploaded in a Secret in the cluster during the uploadcerts init phase. The certificate key is a hex encoded string that is an AES key of size 32 bytes.                                                                                                                                                                                                                                                                                                                                                                                  |
| skipPhases<br><a href="#">[]string</a>                      | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the kubeadm init --help command. The flag "--skip-phases" takes precedence over this field.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| patches<br><a href="#">Patches</a>                          | patches contains options related to applying patches to components deployed by kubeadm during kubeadm init.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## JoinConfiguration

JoinConfiguration contains elements describing a particular node.

| Field                                                       | Description                                                                                                                                                                                        |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                        | kubeadm.k8s.io/v1beta3                                                                                                                                                                             |
| kind<br>string                                              | JoinConfiguration                                                                                                                                                                                  |
| nodeRegistration<br><a href="#">NodeRegistrationOptions</a> | nodeRegistration holds fields that relate to registering the new control-plane node to the cluster.                                                                                                |
| caCertPath<br>string                                        | caCertPath is the path to the SSL certificate authority used to secure communications between a node and the control-plane. Defaults to "/etc/kubernetes/pki/ca.crt".                              |
| discovery <b>[Required]</b><br><a href="#">Discovery</a>    | discovery specifies the options for the kubelet to use during the TLS bootstrap process.                                                                                                           |
| controlPlane<br><a href="#">JoinControlPlane</a>            | controlPlane defines the additional control plane instance to be deployed on the joining node. If nil, no additional control plane instance will be deployed.                                      |
| skipPhases<br>[]string                                      | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the kubeadm join --help command. The flag --skip-phases takes precedence over this field. |
| patches<br><a href="#">Patches</a>                          | patches contains options related to applying patches to components deployed by kubeadm during kubeadm join.                                                                                        |

## APIEndpoint

Appears in:

- [InitConfiguration](#)
- [JoinControlPlane](#)

APIEndpoint struct contains elements of API server instance deployed on a node.

| Field                      | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| advertiseAddress<br>string | advertiseAddress sets the IP address for the API server to advertise.          |
| bindPort<br>int32          | bindPort sets the secure port for the API Server to bind to. Defaults to 6443. |

## APIServer

Appears in:

- [ClusterConfiguration](#)

APIServer holds settings necessary for API server deployments in the cluster

| Field                                                                                 | Description                                                                                  |
|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| ControlPlaneComponent<br>[ <b>Required</b> ]<br><a href="#">ControlPlaneComponent</a> | (Members of ControlPlaneComponent are embedded into this type.) No description provided.     |
| certSANs<br>[]string                                                                  | certSANs sets extra Subject Alternative Names (SANs) for the API Server signing certificate. |
| timeoutForControlPlane<br><a href="#">meta/v1.Duration</a>                            | timeoutForControlPlane controls the timeout that we wait for API server to appear.           |

## BootstrapTokenDiscovery

Appears in:

- [Discovery](#)

BootstrapTokenDiscovery is used to set the options for bootstrap token based discovery.

| Field                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| token [ <b>Required</b> ]<br>string | token is a token used to validate cluster information fetched from the control-plane.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| apiServerEndpoint<br>string         | apiServerEndpoint is an IP or domain name to the API server from which information will be fetched.                                                                                                                                                                                                                                                                                                                                                                                                      |
| caCertHashes<br>[]string            | caCertHashes specifies a set of public key pins to verify when token-based discovery is used. The root CA found during discovery must match one of these values. Specifying an empty set disables root CA pinning, which can be unsafe. Each hash is specified as <type>:<value>, where the only currently supported type is "sha256". This is a hex-encoded SHA-256 hash of the Subject Public Key Info (SPKI) object in DER-encoded ASN.1. These hashes can be calculated using, for example, OpenSSL. |

| Field                            | Description                                                                                                                                                                                  |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| unsafeSkipCAVerification<br>bool | unsafeSkipCAVerification allows token-based discovery without CA verification via caCertHashes. This can weaken the security of kubeadm since other nodes can impersonate the control-plane. |

## ControlPlaneComponent

Appears in:

- [ClusterConfiguration](#)
- [APIServer](#)

ControlPlaneComponent holds settings common to control plane component of the cluster

| Field                                           | Description                                                                                                                                                                      |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extraArgs<br>map[string]string                  | extraArgs is an extra set of flags to pass to the control plane component. A key in this map is the flag name as it appears on the command line except without leading dash(es). |
| extraVolumes<br><a href="#">[]HostPathMount</a> | extraVolumes is an extra set of host volumes, mounted to the control plane component.                                                                                            |

## DNS

Appears in:

- [ClusterConfiguration](#)

DNS defines the DNS addon that should be used in the cluster

| Field                                                | Description                                                                                                                    |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| ImageMeta<br>[Required]<br><a href="#">ImageMeta</a> | (Members of ImageMeta are embedded into this type.)<br><br>imageMeta allows to customize the image used for the DNS component. |

## Discovery

Appears in:

- [JoinConfiguration](#)

Discovery specifies the options for the kubelet to use during the TLS Bootstrap process.

| Field                                                     | Description                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bootstrapToken<br><a href="#">BootstrapTokenDiscovery</a> | bootstrapToken is used to set the options for bootstrap token based discovery. bootstrapToken and file are mutually exclusive.                                                                                                                                                             |
| file<br><a href="#">FileDiscovery</a>                     | file is used to specify a file or URL to a kubeconfig file from which to load cluster information. bootstrapToken and file are mutually exclusive.                                                                                                                                         |
| tlsBootstrapToken<br>string                               | tlsBootstrapToken is a token used for TLS bootstrapping. If bootstrapToken is set, this field is defaulted to .bootstrapToken.token, but can be overridden. If file is set, this field <b>must be set</b> in case the KubeConfigFile does not contain any other authentication information |
| timeout<br><a href="#">meta/v1.Duration</a>               | timeout modifies the discovery timeout.                                                                                                                                                                                                                                                    |

## Etcd

Appears in:

- [ClusterConfiguration](#)

Etcd contains elements describing Etcd configuration.

| Field                                    | Description                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| local<br><a href="#">LocalEtcd</a>       | local provides configuration knobs for configuring the local etcd instance. local and external are mutually exclusive. |
| external<br><a href="#">ExternalEtcd</a> | external describes how to connect to an external etcd cluster. local and external are mutually exclusive.              |

## ExternalEtcd

Appears in:

- [Etcd](#)

ExternalEtcd describes an external etcd cluster. Kubeadm has no knowledge of where certificate files live and they must be supplied.

| Field                               | Description                                  |
|-------------------------------------|----------------------------------------------|
| endpoints<br>[Required]<br>[]string | endpoints contains the list of etcd members. |

| Field                            | Description                                                                                                             |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| caFile<br>[Required]<br>string   | caFile is an SSL Certificate Authority (CA) file used to secure etcd communication. Required if using a TLS connection. |
| certFile<br>[Required]<br>string | certFile is an SSL certification file used to secure etcd communication. Required if using a TLS connection.            |
| keyFile<br>[Required]<br>string  | keyFile is an SSL key file used to secure etcd communication. Required if using a TLS connection.                       |

## FileDiscovery

Appears in:

- [Discovery](#)

FileDiscovery is used to specify a file or URL to a kubeconfig file from which to load cluster information.

| Field                                  | Description                                                                                                                  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| kubeConfigPath<br>[Required]<br>string | kubeConfigPath is used to specify the actual file path or URL to the kubeconfig file from which to load cluster information. |

## HostPathMount

Appears in:

- [ControlPlaneComponent](#)

HostPathMount contains elements describing volumes that are mounted from the host.

| Field                          | Description                                                           |
|--------------------------------|-----------------------------------------------------------------------|
| name [Required]<br>string      | name is the name of the volume inside the Pod template.               |
| hostPath [Required]<br>string  | hostPath is the path in the host that will be mounted inside the Pod. |
| mountPath [Required]<br>string | mountPath is the path inside the Pod where hostPath will be mounted.  |
| readOnly<br>bool               | readOnly controls write access to the volume.                         |

| Field                                            | Description                           |
|--------------------------------------------------|---------------------------------------|
| pathType<br><a href="#">core/v1.HostPathType</a> | pathType is the type of the hostPath. |

## ImageMeta

Appears in:

- [DNS](#)
- [LocalEtcd](#)

ImageMeta allows to customize the image used for components that are not originated from the Kubernetes/Kubernetes release process

| Field                     | Description                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| imageRepository<br>string | imageRepository sets the container registry to pull images from. If not set, the imageRepository defined in ClusterConfiguration will be used instead.                |
| imageTag<br>string        | imageTag allows to specify a tag for the image. In case this value is set, kubeadm does not change automatically the version of the above components during upgrades. |

## JoinControlPlane

Appears in:

- [JoinConfiguration](#)

JoinControlPlane contains elements describing an additional control plane instance to be deployed on the joining node.

| Field                                           | Description                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| localAPIEndpoint<br><a href="#">APIEndpoint</a> | localAPIEndpoint represents the endpoint of the API server instance to be deployed on this node.                                                                                                                                                                                                      |
| certificateKey<br>string                        | certificateKey is the key that is used for decryption of certificates after they are downloaded from the secret upon joining a new control plane node. The corresponding encryption key is in the InitConfiguration. The certificate key is a hex encoded string that is an AES key of size 32 bytes. |

## LocalEtcd

Appears in:

- [Etcd](#)

LocalEtcd describes that kubeadm should run an etcd cluster locally.

| Field                                                | Description                                                                                                                                                                                   |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ImageMeta<br>[Required]<br><a href="#">ImageMeta</a> | (Members of ImageMeta are embedded into this type.)<br><br>ImageMeta allows to customize the container used for etcd.                                                                         |
| dataDir<br>[Required]<br>string                      | dataDir is the directory etcd will place its data. Defaults to "/var/lib/etcd".                                                                                                               |
| extraArgs<br>map[string]string                       | extraArgs are extra arguments provided to the etcd binary when run inside a static Pod. A key in this map is the flag name as it appears on the command line except without leading dash(es). |
| serverCertSANs<br>[]string                           | serverCertSANs sets extra Subject Alternative Names (SANs) for the etcd server signing certificate.                                                                                           |
| peerCertSANs<br>[]string                             | peerCertSANs sets extra Subject Alternative Names (SANs) for the etcd peer signing certificate.                                                                                               |

## Networking

Appears in:

- [ClusterConfiguration](#)

Networking contains elements describing cluster's networking configuration.

| Field                   | Description                                                                           |
|-------------------------|---------------------------------------------------------------------------------------|
| serviceSubnet<br>string | serviceSubnet is the subnet used by Kubernetes Services. Defaults to "10.96.0.0/12".  |
| podSubnet<br>string     | podSubnet is the subnet used by Pods.                                                 |
| dnsDomain<br>string     | dnsDomain is the DNS domain used by Kubernetes Services. Defaults to "cluster.local". |

# NodeRegistrationOptions

Appears in:

- [InitConfiguration](#)
- [JoinConfiguration](#)

NodeRegistrationOptions holds fields that relate to registering a new control-plane or node to the cluster, either via kubeadm init or kubeadm join.

| Field                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name<br>string                                              | name is the .metadata.name field of the Node API object that will be created in this kubeadm init or kubeadm join operation. This field is also used in the CommonName field of the kubelet's client certificate to the API server. Defaults to the hostname of the node if not provided.                                                                                                                                                                                                                            |
| criSocket<br>string                                         | criSocket is used to retrieve container runtime info. This information will be annotated to the Node API object, for later re-use.                                                                                                                                                                                                                                                                                                                                                                                   |
| taints <b>[Required]</b><br><a href="#">[]core/v1.Taint</a> | taints specifies the taints the Node API object should be registered with. If this field is unset, i.e. nil, it will be defaulted with a control-plane taint for control-plane nodes. If you don't want to taint your control-plane node, set this field to an empty list, i.e. taints: [] in the YAML file. This field is solely used for Node registration.                                                                                                                                                        |
| kubeletExtraArgs<br>map[string]string                       | kubeletExtraArgs passes through extra arguments to the kubelet. The arguments here are passed to the kubelet command line via the environment file kubeadm writes at runtime for the kubelet to source. This overrides the generic base-level configuration in the kubelet-config ConfigMap. Flags have higher priority when parsing. These values are local and specific to the node kubeadm is executing on. A key in this map is the flag name as it appears on the command line except without leading dash(es). |
| ignorePreflightErrors<br>[]string                           | ignorePreflightErrors provides a list of pre-flight errors to be ignored when the current node is registered, e.g. IsPrivilegedUser,Swap. Value all ignores errors from all checks.                                                                                                                                                                                                                                                                                                                                  |
| imagePullPolicy<br><a href="#">core/v1.PullPolicy</a>       | imagePullPolicy specifies the policy for image pulling during kubeadm "init" and "join" operations. The value of this field must be one of "Always", "IfNotPresent" or "Never". If this field is not set, kubeadm will default it to "IfNotPresent", or pull the required images if not present on the host.                                                                                                                                                                                                         |

# Patches

Appears in:

- [InitConfiguration](#)
- [JoinConfiguration](#)

Patches contains options related to applying patches to components deployed by kubeadm.

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| directory string | directory is a path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd". "patchtype" can be one of "strategic" "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

## kubeadm Configuration (v1beta4)

### Overview

Package v1beta4 defines the v1beta4 version of the kubeadm configuration file format. This version improves on the v1beta3 format by fixing some minor issues and adding a few new fields.

A list of changes since v1beta3:

- TODO <https://github.com/kubernetes/kubeadm/issues/2890>
- Support custom environment variables in control plane components under ClusterConfiguration. Use APIServer.ExtraEnvs, ControllerManager.ExtraEnvs, Scheduler.ExtraEnvs, EtcLocal.ExtraEnvs.
- The ResetConfiguration API type is now supported in v1beta4. Users are able to reset a node by passing a --config file to kubeadm reset.
- dry-run mode is now configureable in InitConfiguration and JoinConfiguration config files.
- Replace the existing string/string extra argument maps with structured extra arguments that support duplicates. The change applies to ClusterConfiguration - APIServer.ExtraArgs, ControllerManager.ExtraArgs, Scheduler.ExtraArgs. Also to NodeRegistrationOptions.KubeletExtraArgs.
- Add ClusterConfiguration.EncryptionAlgorithm that can be used to set the asymmetric encryption algorithm used for this cluster's keys and certificates. Can be one of "RSA-2048" (default), "RSA-3072", "RSA-4096" or "ECDSA-P256".
- Add ClusterConfiguration.DNS.Disabled and ClusterConfiguration.Proxy.Disabled that can be used to disable the CoreDNS and kube-proxy addons during cluster initialization. Skipping the related addons phases, during cluster creation will set the same fields to false.

- Add the `NodeRegistration.ImagePullSerial` field in `'InitConfigurationandJoinConfiguration'`, which can be used to control if kubeadm pulls images serially or in parallel.
- The `UpgradeConfiguration` kubeadm API is now supported in `v1beta4` when passing `--config` to kubeadm upgrade subcommands. Usage of component configuration for kubelet and kube-proxy, `InitConfiguration` and `ClusterConfiguration` is deprecated and will be ignored when passing `--config` to upgrade subcommands.
- Add a `Timeouts` structure to `InitConfiguration`, `JoinConfiguration`, `ResetConfiguration` and `UpgradeConfiguration` that can be used to configure various timeouts.

## Migration from old kubeadm config versions

- kubeadm `v1.15.x` and newer can be used to migrate from `v1beta1` to `v1beta2`.
- kubeadm `v1.22.x` and newer no longer support `v1beta1` and older APIs, but can be used to migrate `v1beta2` to `v1beta3`.
- kubeadm `v1.27.x` and newer no longer support `v1beta2` and older APIs.
- TODO: <https://github.com/kubernetes/kubeadm/issues/2890> add version that can be used to convert to `v1beta4`

## Basics

The preferred way to configure kubeadm is to pass an YAML configuration file with the `'--config'` option. Some of the configuration options defined in the kubeadm config file are also available as command line flags, but only the most common/simple use case are supported with this approach.

A kubeadm config file could contain multiple configuration types separated using three dashes (`---`).

kubeadm supports the following configuration types:

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: InitConfiguration
```

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: ClusterConfiguration
```

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
```

```
apiVersion: kubeproxy.config.k8s.io/v1alpha1
kind: KubeProxyConfiguration
```

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: JoinConfiguration
```

To print the defaults for "init" and "join" actions use the following commands:

```
kubeadm config print init-defaults
kubeadm config print join-defaults
```

The list of configuration types that must be included in a configuration file depends by the action you are performing (init or join) and by the configuration options you are going to use (defaults or advanced customization).

If some configuration types are not provided, or provided only partially, kubeadm will use default values; defaults provided by kubeadm includes also enforcing consistency of values across components when required (e.g. `--cluster-cidr` flag on controller manager and `clusterCIDR` on kube-proxy).

Users are always allowed to override default values, with the only exception of a small subset of setting with relevance for security (e.g. `enforce authorization-mode` Node and RBAC on api server).

If the user provides a configuration types that is not expected for the action you are performing, kubeadm will ignore those types and print a warning.

## Kubeadm init configuration types

When executing kubeadm init with the `--config` option, the following configuration types could be used: `InitConfiguration`, `ClusterConfiguration`, `KubeProxyConfiguration`, `KubeletConfiguration`, but only one between `InitConfiguration` and `ClusterConfiguration` is mandatory.

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: InitConfiguration
bootstrapTokens:
```

```
...
```

```
nodeRegistration:
```

```
...
```

The `InitConfiguration` type should be used to configure runtime settings, that in case of kubeadm init are the configuration of the bootstrap token and all the setting which are specific to the node where kubeadm is executed, including:

- `NodeRegistration`, that holds fields that relate to registering the new node to the cluster; use it to customize the node name, the CRI socket to use or any other settings that should apply to this node only (e.g. the node ip).
- `LocalAPIEndpoint`, that represents the endpoint of the instance of the API server to be deployed on this node; use it e.g. to customize the API server advertise address.

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: ClusterConfiguration
networking:
```

```
...
```

```
etcd:
```

```
...
```

```
apiServer:
```

```
extraArgs:
```

```
...
```

```
extraVolumes:
```

```
...
```

```
...
```

The ClusterConfiguration type should be used to configure cluster-wide settings, including settings for:

- networking that holds configuration for the networking topology of the cluster; use it e.g. to customize Pod subnet or services subnet.
- etcd: use it e.g. to customize the local etcd or to configure the API server for using an external etcd cluster.
- kube-apiserver, kube-scheduler, kube-controller-manager configurations; use it to customize control-plane components by adding customized setting or overriding kubeadm default settings.

```
apiVersion: kubeproxy.config.k8s.io/v1alpha1
kind: KubeProxyConfiguration
```

```
...
```

The KubeProxyConfiguration type should be used to change the configuration passed to kube-proxy instances deployed in the cluster. If this object is not provided or provided only partially, kubeadm applies defaults.

See <https://kubernetes.io/docs/reference/command-line-tools-reference/kube-proxy/> or <https://pkg.go.dev/k8s.io/kube-proxy/config/v1alpha1#KubeProxyConfiguration> for kube-proxy official documentation.

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
```

```
...
```

The KubeletConfiguration type should be used to change the configurations that will be passed to all kubelet instances deployed in the cluster. If this object is not provided or provided only partially, kubeadm applies defaults.

See <https://kubernetes.io/docs/reference/command-line-tools-reference/kubelet/> or <https://pkg.go.dev/k8s.io/kubelet/config/v1beta1#KubeletConfiguration> for kubelet official documentation.

Here is a fully populated example of a single YAML file containing multiple configuration types to be used during a kubeadm init run.

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: InitConfiguration
bootstrapTokens:

## Kubeadm join configuration types

When executing kubeadm join with the --config option, the JoinConfiguration type should be provided.

```
apiVersion: kubeadm.k8s.io/v1beta4
kind: JoinConfiguration
```

...

The JoinConfiguration type should be used to configure runtime settings, that in case of kubeadm join are the discovery method used for accessing the cluster info and all the setting which are specific to the node where kubeadm is executed, including:

- `nodeRegistration`, that holds fields that relate to registering the new node to the cluster; use it to customize the node name, the CRI socket to use or any other settings that should apply to this node only (e.g. the node ip).
- `apiEndpoint`, that represents the endpoint of the instance of the API server to be eventually deployed on this node.

# BootstrapToken

Appears in:

- [InitConfiguration](#)
- [InitConfiguration](#)

BootstrapToken describes one bootstrap token, stored as a Secret in the cluster

| Field                                                           | Description                                                                                                                                                     |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| token <b>[Required]</b><br><a href="#">BootstrapTokenString</a> | token is used for establishing bidirectional trust between nodes and control-planes. Used for joining nodes in the cluster.                                     |
| description<br>string                                           | description sets a human-friendly message why this token exists and what it's used for, so other administrators can know its purpose.                           |
| ttl<br><a href="#">meta/v1.Duration</a>                         | ttl defines the time to live for this token. Defaults to 24h. expires and ttl are mutually exclusive.                                                           |
| expires<br><a href="#">meta/v1.Time</a>                         | expires specifies the timestamp when this token expires. Defaults to being set dynamically at runtime based on the ttl. expires and ttl are mutually exclusive. |
| usages<br>[]string                                              | usages describes the ways in which this token can be used. Can by default be used for establishing bidirectional trust, but that can be changed here.           |
| groups<br>[]string                                              | groups specifies the extra groups that this token will authenticate as when/if used for authentication                                                          |

# BootstrapTokenString

Appears in:

- [BootstrapToken](#)

BootstrapTokenString is a token of the format abcdef.abcdef0123456789 that is used for both validation of the practically of the API server from a joining node's point of view and as an authentication method for the node in the bootstrap phase of "kubeadm join". This token is and should be short-lived.

| Field                         | Description              |
|-------------------------------|--------------------------|
| - <b>[Required]</b><br>string | No description provided. |

|------------------------|--------------------------|
| - [Required]<br>string | No description provided. |

## ClusterConfiguration

ClusterConfiguration contains cluster-wide configuration for a kubeadm cluster.

| Field                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| encryptionAlgorithm<br><a href="#">EncryptionAlgorithmType</a> | encryptionAlgorithm holds the type of asymmetric encryption algorithm used for keys and certificates. Can be "RSA" (default algorithm, key size is 2048) or "ECDSA" (uses the P-256 elliptic curve).                                                                                                                                                                      |

## InitConfiguration

InitConfiguration contains a list of elements that is specific "kubeadm init"-only runtime information. kubeadm init-only information. These fields are solely used the first time kubeadm init runs. After that, the information in the fields IS NOT uploaded to the kubeadm-config ConfigMap that is used by kubeadm upgrade for instance. These fields must be omitted.

| Field                                               | Description                                                                                                                                                                                                    |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                | kubeadm.k8s.io/v1beta4                                                                                                                                                                                         |
| kind<br>string                                      | InitConfiguration                                                                                                                                                                                              |
| bootstrapTokens<br><a href="#">[]BootstrapToken</a> | bootstrapTokens is respected at kubeadm init time and describes a set of Bootstrap Tokens to create. This information IS NOT uploaded to the kubeadm cluster configmap, partly because of its sensitive nature |
| dryRun <b>[Required]</b><br>bool                    | dryRun tells if the dry run mode is enabled, don't apply any change in dry run mode, just output what would be done.                                                                                           |

| Field                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nodeRegistration<br><a href="#">NodeRegistrationOptions</a> | nodeRegistration holds fields that relate to registering the new control-plane node to the cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| localAPIEndpoint<br><a href="#">APIEndpoint</a>             | localAPIEndpoint represents the endpoint of the API server instance that's deployed on this control plane node. In HA setups, this differs from ClusterConfiguration.controlPlaneEndpoint in the sense that controlPlaneEndpoint is the global endpoint for the cluster, which then loadbalances the requests to each individual API server. This configuration object lets you customize what IP/DNS name and port the local API server advertises it's accessible on. By default, kubeadm tries to auto-detect the IP of the default interface and use that, but in case that process fails you may set the desired value here. |
| certificateKey<br>string                                    | certificateKey sets the key with which certificates and keys are encrypted prior to being uploaded in a Secret in the cluster during the uploadcerts init phase. The certificate key is a hex encoded string that is an AES key of size 32 bytes.                                                                                                                                                                                                                                                                                                                                                                                 |
| skipPhases<br>[]string                                      | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the kubeadm init --help command. The flag --skip-phases takes precedence over this field.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| patches<br><a href="#">Patches</a>                          | patches contains options related to applying patches to components deployed by kubeadm during kubeadm init.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## JoinConfiguration

JoinConfiguration contains elements describing a particular node.

| Field                                                       | Description                                                                                                       |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                        | kubeadm.k8s.io/v1beta4                                                                                            |
| kind<br>string                                              | JoinConfiguration                                                                                                 |
| dryRun<br>bool                                              | dryRun tells if the dry run mode is enabled, don't apply any change if it is set, just output what would be done. |
| nodeRegistration<br><a href="#">NodeRegistrationOptions</a> | nodeRegistration holds fields that relate to registering the new control-plane node to the cluster                |
| caCertPath<br>string                                        |                                                                                                                   |

| Field                                                    | Description                                                                                                                                                                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                          | caCertPath is the path to the SSL certificate authority used to secure communications between node and control-plane. Defaults to <code>"/etc/kubernetes/pki/ca.crt"</code> .                                                |
| discovery <b>[Required]</b><br><a href="#">Discovery</a> | discovery specifies the options for the kubelet to use during the TLS bootstrap process.                                                                                                                                     |
| controlPlane<br><a href="#">JoinControlPlane</a>         | controlPlane defines the additional control plane instance to be deployed on the joining node. If nil, no additional control plane instance will be deployed.                                                                |
| skipPhases<br>[]string                                   | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the <code>kubeadm join --help</code> command. The flag <code>--skip-phases</code> takes precedence over this field. |
| patches<br><a href="#">Patches</a>                       | patches contains options related to applying patches to components deployed by kubeadm during kubeadm join.                                                                                                                  |

## ResetConfiguration

ResetConfiguration contains a list of fields that are specifically kubeadm reset-only runtime information.

| Field                     | Description                                                                                                                                                                                                            |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string      | kubeadm.k8s.io/v1beta4                                                                                                                                                                                                 |
| kind<br>string            | ResetConfiguration                                                                                                                                                                                                     |
| cleanupTmpDir<br>bool     | cleanupTmpDir specifies whether the <code>"/etc/kubernetes/tmp"</code> directory should be cleaned during the reset process.                                                                                           |
| certificatesDir<br>string | certificatesDir specifies the directory where the certificates are stored. If specified, it will be cleaned during the reset process.                                                                                  |
| criSocket<br>string       | criSocket is used to retrieve container runtime information and used for the removal of the containers. If criSocket is not specified by flag or config file, kubeadm will try to detect one valid CRI socket instead. |
| dryRun<br>bool            | dryRun tells if the dry run mode is enabled, don't apply any change if it is set and just output what would be done.                                                                                                   |

| Field                             | Description                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| force<br>bool                     | The force flag instructs kubeadm to reset the node without prompting for confirmation.                                                                                   |
| ignorePreflightErrors<br>[]string | ignorePreflightErrors provides a list of pre-flight errors to be ignored during the reset process, e.g. IsPrivilegedUser,Swap. Value all ignores errors from all checks. |
| skipPhases<br>[]string            | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the kubeadm reset phase --help command.                         |

## UpgradeConfiguration

UpgradeConfiguration contains a list of options that are specific to kubeadm upgrade subcommands.

| Field                                              | Description                                                                           |
|----------------------------------------------------|---------------------------------------------------------------------------------------|
| apiVersion<br>string                               | kubeadm.k8s.io/v1beta4                                                                |
| kind<br>string                                     | UpgradeConfiguration                                                                  |
| apply<br><a href="#">UpgradeApplyConfiguration</a> | apply holds a list of options that are specific to the kubeadm upgrade apply command. |
| diff<br><a href="#">UpgradeDiffConfiguration</a>   | diff holds a list of options that are specific to the kubeadm upgrade diff command.   |
| node<br><a href="#">UpgradeNodeConfiguration</a>   | node holds a list of options that are specific to the kubeadm upgrade node command.   |
| plan<br><a href="#">UpgradePlanConfiguration</a>   | plan holds a list of options that are specific to the kubeadm upgrade plan command.   |
| timeouts<br><a href="#">Timeouts</a>               | timeouts holds various timeouts that apply to kubeadm commands.                       |

## APIEndpoint

Appears in:

- [InitConfiguration](#)

- [JoinControlPlane](#)

APIEndpoint struct contains elements of API server instance deployed on a node.

| Field                      | Description                                                                    |
|----------------------------|--------------------------------------------------------------------------------|
| advertiseAddress<br>string | advertiseAddress sets the IP address for the API server to advertise.          |
| bindPort<br>int32          | bindPort sets the secure port for the API Server to bind to. Defaults to 6443. |

## APIServer

Appears in:

- [ClusterConfiguration](#)

APIServer holds settings necessary for API server deployments in the cluster

| Field                                                                                 | Description                                                                                  |
|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| ControlPlaneComponent<br>[ <b>Required</b> ]<br><a href="#">ControlPlaneComponent</a> | (Members of ControlPlaneComponent are embedded into this type.) No description provided.     |
| certSANs<br>[]string                                                                  | certSANs sets extra Subject Alternative Names (SANs) for the API Server signing certificate. |
| timeoutForControlPlane<br><a href="#">meta/v1.Duration</a>                            | timeoutForControlPlane controls the timeout that we use for API server to appear.            |

## Arg

Appears in:

- [ControlPlaneComponent](#)
- [LocalEtcd](#)
- [NodeRegistrationOptions](#)

Arg represents an argument with a name and a value.

| Field                               | Description                |
|-------------------------------------|----------------------------|
| name [ <b>Required</b> ]<br>string  | The name of the argument.  |
| value [ <b>Required</b> ]<br>string | The value of the argument. |

# BootstrapTokenDiscovery

Appears in:

- [Discovery](#)

BootstrapTokenDiscovery is used to set the options for bootstrap token based discovery.

| Field                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| token <b>[Required]</b><br>string | token is a token used to validate cluster information fetched from the control-plane.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| apiServerEndpoint<br>string       | apiServerEndpoint is an IP or domain name to the API server from which information will be fetched.                                                                                                                                                                                                                                                                                                                                                                                                         |
| caCertHashes<br>[]string          | caCertHashes specifies a set of public key pins to verify when token-based discovery is used. The root CA found during discovery must match one of these values. Specifying an empty set disables root CA pinning, which can be unsafe. Each hash is specified as <type>:<value>, where the only currently supported type is "sha256". This is a hex-encoded SHA-256 hash of the Subject Public Key Info (SPKI) object in DER-encoded ASN.1. These hashes can be // calculated using, for example, OpenSSL. |
| unsafeSkipCAVerification<br>bool  | unsafeSkipCAVerification allows token-based discovery without CA verification via caCertHashes. This can weaken the security of kubeadm since other nodes can impersonate the control-plane.                                                                                                                                                                                                                                                                                                                |

# ControlPlaneComponent

Appears in:

- [ClusterConfiguration](#)
- [APIServer](#)

ControlPlaneComponent holds settings common to control plane component of the cluster

| Field                                           | Description                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extraArgs<br><a href="#">[]Arg</a>              | extraArgs is an extra set of flags to pass to the control plane component. An argument name in this list is the flag name as it appears on the command line except without leading dash(es). Extra arguments will override existing default arguments. Duplicate extra arguments are allowed. |
| extraVolumes<br><a href="#">[]HostPathMount</a> |                                                                                                                                                                                                                                                                                               |

| Field                                 | Description                                                                                                                                                                                                                                              |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | extraVolumes is an extra set of host volumes, mounted to the control plane component.                                                                                                                                                                    |
| extraEnvs<br><a href="#">[]EnvVar</a> | extraEnvs is an extra set of environment variables to pass to the control plane component. Environment variables passed using extraEnvs will override any existing environment variables, or *_proxy environment variables that kubeadm adds by default. |

## DNS

Appears in:

- [ClusterConfiguration](#)

DNS defines the DNS addon that should be used in the cluster

| Field                                                    | Description                                                                                                            |
|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| ImageMeta <b>[Required]</b><br><a href="#">ImageMeta</a> | (Members of ImageMeta are embedded into this type.)<br>imageMeta allows to customize the image used for the DNS addon. |
| disabled <b>[Required]</b><br>bool                       | disabled specifies whether to disable this addon in the cluster.                                                       |

## Discovery

Appears in:

- [JoinConfiguration](#)

Discovery specifies the options for the kubelet to use during the TLS Bootstrap process

| Field                                                     | Description                                                                                                                                                                                                          |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bootstrapToken<br><a href="#">BootstrapTokenDiscovery</a> | bootstrapToken is used to set the options for bootstrap token based discovery. bootstrapToken and file are mutually exclusive.                                                                                       |
| file<br><a href="#">FileDiscovery</a>                     | file is used to specify a file or URL to a kubeconfig file from which to load cluster information. bootstrapToken and file are mutually exclusive.                                                                   |
| tlsBootstrapToken<br>string                               | tlsBootstrapToken is a token used for TLS bootstrapping. If bootstrapToken is set, this field is defaulted to bootstrapToken.token, but can be overridden. If file is set, this field <b>must be set</b> in case the |

| Field                                       | Description                                                           |
|---------------------------------------------|-----------------------------------------------------------------------|
|                                             | KubeConfigFile does not contain any other authentication information. |
| timeout<br><a href="#">meta/v1.Duration</a> | timeout modifies the discovery timeout.                               |

## EncryptionAlgorithmType

(Alias of string)

Appears in:

- [ClusterConfiguration](#)

EncryptionAlgorithmType can define an asymmetric encryption algorithm type.

## EnvVar

Appears in:

- [ControlPlaneComponent](#)
- [LocalEtcd](#)

EnvVar represents an environment variable present in a Container.

| Field                                                  | Description                                                               |
|--------------------------------------------------------|---------------------------------------------------------------------------|
| EnvVar<br>[Required]<br><a href="#">core/v1.EnvVar</a> | (Members of EnvVar are embedded into this type.) No description provided. |

## Etcd

Appears in:

- [ClusterConfiguration](#)

Etcd contains elements describing Etcd configuration.

| Field                                    | Description                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| local<br><a href="#">LocalEtcd</a>       | local provides configuration knobs for configuring the local etcd instance. local and external are mutually exclusive. |
| external<br><a href="#">ExternalEtcd</a> | external describes how to connect to an external etcd cluster. local and external are mutually exclusive.              |

## ExternalEtcd

Appears in:

- [Etcd](#)

ExternalEtcd describes an external etcd cluster. Kubeadm has no knowledge of where certificate files live and they must be supplied.

| Field                               | Description                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| endpoints<br>[Required]<br>[]string | endpoints contains the list of etcd members.                                                                            |
| caFile<br>[Required]<br>string      | caFile is an SSL Certificate Authority (CA) file used to secure etcd communication. Required if using a TLS connection. |
| certFile<br>[Required]<br>string    | certFile is an SSL certification file used to secure etcd communication. Required if using a TLS connection.            |
| keyFile<br>[Required]<br>string     | keyFile is an SSL key file used to secure etcd communication. Required if using a TLS connection.                       |

## FileDiscovery

Appears in:

- [Discovery](#)

FileDiscovery is used to specify a file or URL to a kubeconfig file from which to load cluster information.

| Field                                  | Description                                                                                                                  |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| kubeConfigPath<br>[Required]<br>string | kubeConfigPath is used to specify the actual file path or URL to the kubeconfig file from which to load cluster information. |

## HostPathMount

Appears in:

- [ControlPlaneComponent](#)

HostPathMount contains elements describing volumes that are mounted from the host.

| Field                                            | Description                                                           |
|--------------------------------------------------|-----------------------------------------------------------------------|
| name <b>[Required]</b><br>string                 | name is the name of the volume inside the Pod template.               |
| hostPath <b>[Required]</b><br>string             | hostPath is the path in the host that will be mounted inside the Pod. |
| mountPath <b>[Required]</b><br>string            | mountPath is the path inside the Pod where hostPath will be mounted.  |
| readOnly<br>bool                                 | readOnly controls write access to the volume.                         |
| pathType<br><a href="#">core/v1.HostPathType</a> | pathType is the type of the hostPath.                                 |

## ImageMeta

Appears in:

- [DNS](#)
- [LocalEtcd](#)

ImageMeta allows to customize the image used for components that are not originated from the Kubernetes/Kubernetes release process

| Field                     | Description                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| imageRepository<br>string | imageRepository sets the container registry to pull images from. if not set, the imageRepository defined in ClusterConfiguration will be used instead.                |
| imageTag<br>string        | imageTag allows to specify a tag for the image. In case this value is set, kubeadm does not change automatically the version of the above components during upgrades. |

## JoinControlPlane

Appears in:

- [JoinConfiguration](#)

JoinControlPlane contains elements describing an additional control plane instance to be deployed on the joining node.

| Field                                           | Description                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| localAPIEndpoint<br><a href="#">APIEndpoint</a> | localAPIEndpoint represents the endpoint of the API server instance to be deployed on this node.                                                                                                                                                                                                      |
| certificateKey<br>string                        | certificateKey is the key that is used for decryption of certificates after they are downloaded from the Secret upon joining a new control plane node. The corresponding encryption key is in the InitConfiguration. The certificate key is a hex encoded string that is an AES key of size 32 bytes. |

## LocalEtcd

Appears in:

- [Etcd](#)

LocalEtcd describes that kubeadm should run an etcd cluster locally.

| Field                                                       | Description                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ImageMeta<br><b>[Required]</b><br><a href="#">ImageMeta</a> | (Members of ImageMeta are embedded into this type.)<br><br>ImageMeta allows to customize the container used for etcd                                                                                                                                                                                       |
| dataDir<br><b>[Required]</b><br>string                      | dataDir is the directory etcd will place its data. Defaults to "/var/lib/etcd".                                                                                                                                                                                                                            |
| extraArgs<br><b>[Required]</b><br><a href="#">[]Arg</a>     | extraArgs are extra arguments provided to the etcd binary when run inside a static Pod. An argument name in this list is the flag name as it appears on the command line except without leading dash(es). Extra arguments will override existing default arguments. Duplicate extra arguments are allowed. |
| extraEnvs<br><a href="#">[]EnvVar</a>                       | extraEnvs is an extra set of environment variables to pass to the control plane component. Environment variables passed using extraEnvs will override any existing environment variables, or *_proxy environment variables that kubeadm adds by default.                                                   |
| serverCertSANs<br><a href="#">[]string</a>                  | serverCertSANs sets extra Subject Alternative Names (SANs) for the etcd server signing certificate.                                                                                                                                                                                                        |
| peerCertSANs<br><a href="#">[]string</a>                    | peerCertSANs sets extra Subject Alternative Names (SANs) for the etcd peer signing certificate.                                                                                                                                                                                                            |

# Networking

Appears in:

- [ClusterConfiguration](#)

Networking contains elements describing cluster's networking configuration.

| Field                   | Description                                                                           |
|-------------------------|---------------------------------------------------------------------------------------|
| serviceSubnet<br>string | serviceSubnet is the subnet used by Kubernetes Services. Defaults to "10.96.0.0/12".  |
| podSubnet<br>string     | podSubnet is the subnet used by Pods.                                                 |
| dnsDomain<br>string     | dnsDomain is the dns domain used by Kubernetes Services. Defaults to "cluster.local". |

# NodeRegistrationOptions

Appears in:

- [InitConfiguration](#)
- [JoinConfiguration](#)

NodeRegistrationOptions holds fields that relate to registering a new control-plane or node to the cluster, either via kubeadm init or kubeadm join.

| Field                                                       | Description                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name<br>string                                              | name is the .Metadata.Name field of the Node API object that will be created in this kubeadm init or kubeadm join operation. This field is also used in the CommonName field of the kubelet's client certificate to the API server. Defaults to the hostname of the node if not provided.                                                                     |
| criSocket<br>string                                         | criSocket is used to retrieve container runtime info. This information will be annotated to the Node API object, for later re-use.                                                                                                                                                                                                                            |
| taints <b>[Required]</b><br><a href="#">[]core/v1.Taint</a> | taints specifies the taints the Node API object should be registered with. If this field is unset, i.e. nil, it will be defaulted with a control-plane taint for control-plane nodes. If you don't want to taint your control-plane node, set this field to an empty list, i.e. taints: [] in the YAML file. This field is solely used for Node registration. |
| kubeletExtraArgs<br><a href="#">[]Arg</a>                   | kubeletExtraArgs passes through extra arguments to the kubelet. The arguments here are passed to the kubelet command line via the                                                                                                                                                                                                                             |

| Field                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                       | environment file kubeadm writes at runtime for the kubelet to source. This overrides the generic base-level configuration in the kubelet-config ConfigMap. Flags have higher priority when parsing. These values are local and specific to the node kubeadm is executing on. An argument name in this list is the flag name as it appears on the command line except without leading dash(es). Extra arguments will override existing default arguments. Duplicate extra arguments are allowed. |
| ignorePreflightErrors<br>[]string                     | ignorePreflightErrors provides a slice of pre-flight errors to be ignored when the current node is registered, e.g. 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks.                                                                                                                                                                                                                                                                                                        |
| imagePullPolicy<br><a href="#">core/v1.PullPolicy</a> | imagePullPolicy specifies the policy for image pulling during kubeadm init and join operations. The value of this field must be one of "Always", "IfNotPresent" or "Never". If this field is unset kubeadm will default it to "IfNotPresent", or pull the required images if not present on the host.                                                                                                                                                                                           |

## Patches

Appears in:

- [InitConfiguration](#)
- [JoinConfiguration](#)
- [UpgradeApplyConfiguration](#)
- [UpgradeNodeConfiguration](#)

Patches contains options related to applying patches to components deployed by kubeadm.

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| directory<br>string | directory is a path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectrl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

## Proxy

Appears in:

- [ClusterConfiguration](#)

Proxy defines the proxy addon that should be used in the cluster.

| Field                              | Description                                                      |
|------------------------------------|------------------------------------------------------------------|
| disabled <b>[Required]</b><br>bool | disabled specifies whether to disable this addon in the cluster. |

## Timeouts

Appears in:

- [UpgradeConfiguration](#)

Timeouts holds various timeouts that apply to kubeadm commands.

| Field                                                                  | Description                                                                                                                                                                           |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| controlPlaneComponentHealthCheck<br><a href="#">meta/v1.Duration</a>   | controlPlaneComponentHealthCheck is the amount of time to wait for a control plane component, such as the API server, to be healthy during kubeadm init and kubeadm join. Default: 4m |
| kubeletHealthCheck<br><a href="#">meta/v1.Duration</a>                 | kubeletHealthCheck is the amount of time to wait for the kubelet to be healthy during kubeadm init and kubeadm join. Default: 4m                                                      |
| kubernetesAPICall<br><a href="#">meta/v1.Duration</a>                  | kubernetesAPICall is the amount of time to wait for the kubeadm client to complete a request to the API server. This applies to all types of methods (GET, POST, etc). Default: 1m    |
| etcdAPICall<br><a href="#">meta/v1.Duration</a>                        | etcdAPICall is the amount of time to wait for the kubeadm etcd client to complete a request to the etcd cluster. Default: 2m                                                          |
| tlsBootstrap<br><a href="#">meta/v1.Duration</a>                       | tlsBootstrap is the amount of time to wait for the kubelet to complete TLS bootstrap for a joining node. Default: 5m                                                                  |
| discovery<br><a href="#">meta/v1.Duration</a>                          | discovery is the amount of time to wait for kubeadm to validate the API server identity for a joining node. Default: 5m                                                               |
| upgradeManifests <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | upgradeManifests is the timeout for upgrading static Pod manifests Default: 5m                                                                                                        |

# UpgradeApplyConfiguration

Appears in:

- [UpgradeConfiguration](#)

UpgradeApplyConfiguration contains a list of configurable options which are specific to the "kubeadm upgrade apply" command.

| Field                              | Description                                                                                                                                                                                                 |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kubernetesVersion<br>string        | kubernetesVersion is the target version of the control plane.                                                                                                                                               |
| allowExperimentalUpgrades<br>bool  | allowExperimentalUpgrades instructs kubeadm to show unstable versions of Kubernetes as an upgrade alternative and allows upgrading to an alpha/beta/release candidate version of Kubernetes. Default: false |
| allowRCUpgrades<br>bool            | Enable allowRCUpgrades will show release candidate versions of Kubernetes as an upgrade alternative and allows upgrading to a release candidate version of Kubernetes.                                      |
| certificateRenewal<br>bool         | certificateRenewal instructs kubeadm to execute certificate renewal during upgrades. Defaults to true.                                                                                                      |
| dryRun<br>bool                     | dryRun tells if the dry run mode is enabled, don't apply any change if it is and just output what would be done.                                                                                            |
| etcdUpgrade<br>bool                | etcdUpgrade instructs kubeadm to execute etcd upgrade during upgrades. Defaults to true.                                                                                                                    |
| forceUpgrade<br>bool               | forceUpgrade flag instructs kubeadm to upgrade the cluster without prompting for confirmation.                                                                                                              |
| ignorePreflightErrors<br>[]string  | ignorePreflightErrors provides a slice of pre-flight errors to be ignored during the upgrade process, e.g. 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks.                             |
| patches<br><a href="#">Patches</a> | patches contains options related to applying patches to components deployed by kubeadm during "kubeadm upgrade".                                                                                            |
| printConfig<br>bool                | printConfig specifies whether the configuration file that will be used in the upgrade should be printed or not.                                                                                             |

| Field                                    | Description                                                                                                                                                                    |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SkipPhases <b>[Required]</b><br>[]string | skipPhases is a list of phases to skip during command execution.<br>NOTE: This field is currently ignored for "kubeadm upgrade apply", but in the future it will be supported. |

## UpgradeDiffConfiguration

Appears in:

- [UpgradeConfiguration](#)

UpgradeDiffConfiguration contains a list of configurable options which are specific to the "kubeadm upgrade diff" command.

| Field                       | Description                                                     |
|-----------------------------|-----------------------------------------------------------------|
| kubernetesVersion<br>string | kubernetesVersion is the target version of the control plane.   |
| contextLines<br>int         | diffContextLines is the number of lines of context in the diff. |

## UpgradeNodeConfiguration

Appears in:

- [UpgradeConfiguration](#)

UpgradeNodeConfiguration contains a list of configurable options which are specific to the "kubeadm upgrade node" command.

| Field                             | Description                                                                                                                                                                     |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| certificateRenewal<br>bool        | certificateRenewal instructs kubeadm to execute certificate renewal during upgrades. Defaults to true.                                                                          |
| dryRun<br>bool                    | dryRun tells if the dry run mode is enabled, don't apply any change if it is and just output what would be done.                                                                |
| etcdUpgrade<br>bool               | etcdUpgrade instructs kubeadm to execute etcd upgrade during upgrades. Defaults to true.                                                                                        |
| ignorePreflightErrors<br>[]string | ignorePreflightErrors provides a slice of pre-flight errors to be ignored during the upgrade process, e.g. 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks. |

| Field                              | Description                                                                                                                                             |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| skipPhases<br>[]string             | skipPhases is a list of phases to skip during command execution. The list of phases can be obtained with the kubeadm upgrade node phase --help command. |
| patches<br><a href="#">Patches</a> | patches contains options related to applying patches to components deployed by kubeadm during kubeadm upgrade.                                          |

## UpgradePlanConfiguration

Appears in:

- [UpgradeConfiguration](#)

UpgradePlanConfiguration contains a list of configurable options which are specific to the "kubeadm upgrade plan" command.

| Field                                            | Description                                                                                                                                                                                                 |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kubernetesVersion<br><b>[Required]</b><br>string | kubernetesVersion is the target version of the control plane.                                                                                                                                               |
| allowExperimentalUpgrades<br>bool                | allowExperimentalUpgrades instructs kubeadm to show unstable versions of Kubernetes as an upgrade alternative and allows upgrading to an alpha/beta/release candidate version of Kubernetes. Default: false |
| allowRCUpgrades<br>bool                          | Enable allowRCUpgrades will show release candidate versions of Kubernetes as an upgrade alternative and allows upgrading to a release candidate version of Kubernetes.                                      |
| dryRun<br>bool                                   | dryRun tells if the dry run mode is enabled, don't apply any change if it is and just output what would be done.                                                                                            |
| ignorePreflightErrors<br>[]string                | ignorePreflightErrors provides a slice of pre-flight errors to be ignored during the upgrade process, e.g. 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks.                             |
| printConfig<br>bool                              | printConfig specifies whether the configuration file that will be used in the upgrade should be printed or not.                                                                                             |

# kubeconfig (v1)

## Resource Types

- [Config](#)

### Config

Config holds the information needed to build connect to remote kubernetes clusters as a given user

| Field                                                             | Description                                                                                                                 |
|-------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                              | /v1                                                                                                                         |
| kind<br>string                                                    | Config                                                                                                                      |
| kind<br>string                                                    | Legacy field from pkg/api/types.go TypeMeta. TODO(jlowdermilk): remove this after eliminating downstream dependencies.      |
| apiVersion<br>string                                              | Legacy field from pkg/api/types.go TypeMeta. TODO(jlowdermilk): remove this after eliminating downstream dependencies.      |
| preferences<br>[ <b>Required</b> ]<br><a href="#">Preferences</a> | Preferences holds general information to be use for cli interactions                                                        |
| clusters [ <b>Required</b> ]<br><a href="#">[]NamedCluster</a>    | Clusters is a map of referencable names to cluster configs                                                                  |
| users [ <b>Required</b> ]<br><a href="#">[]NamedAuthInfo</a>      | AuthInfos is a map of referencable names to user configs                                                                    |
| contexts [ <b>Required</b> ]<br><a href="#">[]NamedContext</a>    | Contexts is a map of referencable names to context configs                                                                  |
| current-context<br>[ <b>Required</b> ]<br>string                  | CurrentContext is the name of the context that you would like to use by default                                             |
| extensions<br><a href="#">[]NamedExtension</a>                    | Extensions holds additional information. This is useful for extenders so that reads and writes don't clobber unknown fields |

### AuthInfo

Appears in:

- [NamedAuthInfo](#)

AuthInfo contains information that describes identity information. This is use to tell the kubernetes cluster who you are.

| Field                                               | Description                                                                                                                                          |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| client-certificate-string                           | ClientCertificate is the path to a client cert file for TLS.                                                                                         |
| client-certificate-data<br>[]byte                   | ClientCertificateData contains PEM-encoded data from a client cert file for TLS. Overrides ClientCertificate                                         |
| client-key-string                                   | ClientKey is the path to a client key file for TLS.                                                                                                  |
| client-key-data<br>[]byte                           | ClientKeyData contains PEM-encoded data from a client key file for TLS. Overrides ClientKey                                                          |
| token-string                                        | Token is the bearer token for authentication to the kubernetes cluster.                                                                              |
| tokenFile-string                                    | TokenFile is a pointer to a file that contains a bearer token (as described above). If both Token and TokenFile are present, Token takes precedence. |
| as-string                                           | Impersonate is the username to impersonate. The name matches the flag.                                                                               |
| as-uid-string                                       | ImpersonateUID is the uid to impersonate.                                                                                                            |
| as-groups<br>[]string                               | ImpersonateGroups is the groups to impersonate.                                                                                                      |
| as-user-extra<br>map[string][]string                | ImpersonateUserExtra contains additional information for impersonated user.                                                                          |
| username-string                                     | Username is the username for basic authentication to the kubernetes cluster.                                                                         |
| password-string                                     | Password is the password for basic authentication to the kubernetes cluster.                                                                         |
| auth-provider<br><a href="#">AuthProviderConfig</a> | AuthProvider specifies a custom authentication plugin for the kubernetes cluster.                                                                    |
| exec<br><a href="#">ExecConfig</a>                  | Exec specifies a custom exec-based authentication plugin for the kubernetes cluster.                                                                 |

| Field                                          | Description                                                                                                                 |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| extensions<br><a href="#">[]NamedExtension</a> | Extensions holds additional information. This is useful for extenders so that reads and writes don't clobber unknown fields |

## AuthProviderConfig

Appears in:

- [AuthInfo](#)

AuthProviderConfig holds the configuration for a specified auth provider.

| Field                                         | Description              |
|-----------------------------------------------|--------------------------|
| name <b>[Required]</b><br>string              | No description provided. |
| config <b>[Required]</b><br>map[string]string | No description provided. |

## Cluster

Appears in:

- [NamedCluster](#)

Cluster contains information about how to communicate with a kubernetes cluster

| Field                                | Description                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server <b>[Required]</b><br>string   | Server is the address of the kubernetes cluster (https://hostname:port).                                                                                                                                                                                                                           |
| tls-server-name<br>string            | TLSServerName is used to check server certificate. If TLSServerName is empty, the hostname used to contact the server is used.                                                                                                                                                                     |
| insecure-skip-tls-verify<br>bool     | InsecureSkipTLSVerify skips the validity check for the server's certificate. This will make your HTTPS connections insecure.                                                                                                                                                                       |
| certificate-authority<br>string      | CertificateAuthority is the path to a cert file for the certificate authority.                                                                                                                                                                                                                     |
| certificate-authority-data<br>[]byte | CertificateAuthorityData contains PEM-encoded certificate authority certificates. Overrides CertificateAuthority                                                                                                                                                                                   |
| proxy-url<br>string                  | ProxyURL is the URL to the proxy to be used for all requests made by this client. URLs with "http", "https", and "socks5" schemes are supported. If this configuration is not provided or the empty string, the client attempts to construct a proxy configuration from http_proxy and https_proxy |

| Field                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | environment variables. If these environment variables are not set, the client does not attempt to proxy requests.<br><br>socks5 proxying does not currently support spdy streaming endpoints (exec, attach, port forward).                                                                                                                                                                                             |
| disable-compression<br>bool                    | DisableCompression allows client to opt-out of response compression for all requests to the server. This is useful to speed up requests (specifically lists) when client-server network bandwidth is ample, by saving time on compression (server-side) and decompression (client-side): <a href="https://github.com/kubernetes/kubernetes/issues/112296">https://github.com/kubernetes/kubernetes/issues/112296</a> . |
| extensions<br><a href="#">[]NamedExtension</a> | Extensions holds additional information. This is useful for extenders so that reads and writes don't clobber unknown fields                                                                                                                                                                                                                                                                                            |

## Context

Appears in:

- [NamedContext](#)

Context is a tuple of references to a cluster (how do I communicate with a kubernetes cluster), a user (how do I identify myself), and a namespace (what subset of resources do I want to work with)

| Field                                          | Description                                                                                                                 |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| cluster<br>[Required]<br>string                | Cluster is the name of the cluster for this context                                                                         |
| user [Required]<br>string                      | AuthInfo is the name of the authInfo for this context                                                                       |
| namespace<br>string                            | Namespace is the default namespace to use on unspecified requests                                                           |

## ExecConfig

Appears in:

- [AuthInfo](#)

ExecConfig specifies a command to provide client credentials. The command is exec'd and outputs structured stdout holding credentials.

See the `client.authentication.k8s.io` API group for specifications of the exact input and output format

| Field                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# Kubelet Configuration (v1)

## Resource Types

- [CredentialProviderConfig](#)

## CredentialProviderConfig

CredentialProviderConfig is the configuration containing information about each exec credential provider. Kubelet reads this configuration from disk and enables each provider as specified by the CredentialProvider type.

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                    |

| providers<br>[ <b>Required</b> ]<br><a href="#">[]CredentialProvider</a> | providers is a list of credential provider plugins that will be enabled by the kubelet. Multiple providers may match against a single image, in which case credentials from all providers will be returned to the kubelet. If multiple providers are called for a single image, the results are combined. If providers return overlapping auth keys, the value from the provider earlier in this list is used. |

## CredentialProvider

Appears in:

- [CredentialProviderConfig](#)

CredentialProvider represents an exec plugin to be invoked by the kubelet. The plugin is only invoked when an image being pulled matches the images handled by the plugin (see matchImages).

| Field                              | Description                                                                                                                                                                                                                                  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name [ <b>Required</b> ]<br>string | name is the required name of the credential provider. It must match the name of the provider executable as seen by the kubelet. The executable must be in the kubelet's bin directory (set by the --image-credential-provider-bin-dir flag). |

| Field                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| matchImages<br><b>[Required]</b><br>[]string                                  | <p>matchImages is a required list of strings used to match against images in order to determine if this provider should be invoked. If one of the strings matches the requested image from the kubelet, the plugin will be invoked and given a chance to provide credentials. Images are expected to contain the registry domain and URL path.</p> <p>Each entry in matchImages is a pattern which can optionally contain a port and a path. Globs can be used in the domain, but not in the port or the path. Globs are supported as subdomains like '*.k8s.io' or 'k8s.*.io', and top-level-domains such as 'k8s.*'. Matching partial subdomains like 'app*.k8s.io' is also supported. Each glob can only match a single subdomain segment, so '*.io' does not match '*.k8s.io'.</p> <p>A match exists between an image and a matchImage when all of the below are true:</p> <ul style="list-style-type: none"> <li>• Both contain the same number of domain parts and each part matches.</li> <li>• The URL path of an imageMatch must be a prefix of the target image URL path.</li> <li>• If the imageMatch contains a port, then the port must match in the image as well.</li> </ul> <p>Example values of matchImages:</p> <ul style="list-style-type: none"> <li>• 123456789.dkr.ecr.us-east-1.amazonaws.com</li> <li>• *.azurecr.io</li> <li>• gcr.io</li> <li>• *.registry.io</li> <li>• registry.io:8080/path</li> </ul> |
| defaultCacheDuration<br><b>[Required]</b><br><a href="#">meta/v1.Duration</a> | defaultCacheDuration is the default duration the plugin will cache credentials in-memory if a cache duration is not provided in the plugin response. This field is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| apiVersion<br><b>[Required]</b><br>string                                     | <p>Required input version of the exec CredentialProviderRequest. The returned CredentialProviderResponse MUST use the same encoding version as the input. Current supported values are:</p> <ul style="list-style-type: none"> <li>• credentialprovider.kubelet.k8s.io/v1</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Kubelet Configuration (v1alpha1)

### Resource Types

- [CredentialProviderConfig](#)

## CredentialProviderConfig

CredentialProviderConfig is the configuration containing information about each exec credential provider. Kubelet reads this configuration from disk and enables each provider as specified by the CredentialProvider type.

| providers<br>[Required]<br><a href="#">[]CredentialProvider</a> | providers is a list of credential provider plugins that will be enabled by the kubelet. Multiple providers may match against a single image, in which case credentials from all providers will be returned to the kubelet. If multiple providers are called for a single image, the results are combined. If providers return overlapping auth keys, the value from the provider earlier in this list is used. |

## CredentialProvider

Appears in:

- [CredentialProviderConfig](#)

CredentialProvider represents an exec plugin to be invoked by the kubelet. The plugin is only invoked when an image being pulled matches the images handled by the plugin (see `matchImages`).

| Field                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code> <b>[Required]</b><br>string                                           | <code>name</code> is the required name of the credential provider. It must match the name of the provider executable as seen by the kubelet. The executable must be in the kubelet's bin directory (set by the <code>--image-credential-provider-bin-dir</code> flag).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>matchImages</code> <b>[Required]</b><br>[]string                                  | <p><code>matchImages</code> is a required list of strings used to match against images in order to determine if this provider should be invoked. If one of the strings matches the requested image from the kubelet, the plugin will be invoked and given a chance to provide credentials. Images are expected to contain the registry domain and URL path.</p> <p>Each entry in <code>matchImages</code> is a pattern which can optionally contain a port and a path. Globs can be used in the domain, but not in the port or the path. Globs are supported as subdomains like <code>*.k8s.io</code> or <code>k8s*.io</code>, and top-level-domains such as <code>k8s.*</code>. Matching partial subdomains like <code>app*.k8s.io</code> is also supported. Each glob can only match a single subdomain segment, so <code>*.io</code> does not match <code>*.k8s.io</code>.</p> <p>A match exists between an image and a <code>matchImage</code> when all of the below are true:</p> <ul style="list-style-type: none"><li>• Both contain the same number of domain parts and each part matches.</li><li>• The URL path of an <code>imageMatch</code> must be a prefix of the target image URL path.</li><li>• If the <code>imageMatch</code> contains a port, then the port must match in the image as well.</li></ul> <p>Example values of <code>matchImages</code>:</p> <ul style="list-style-type: none"><li>• <code>123456789.dkr.ecr.us-east-1.amazonaws.com</code></li><li>• <code>*.azurecr.io</code></li><li>• <code>gcr.io</code></li><li>• <code>*.*.registry.io</code></li><li>• <code>registry.io:8080/path</code></li></ul> |
| <code>defaultCacheDuration</code> <b>[Required]</b><br><a href="#">meta/v1.Duration</a> | <code>defaultCacheDuration</code> is the default duration the plugin will cache credentials in-memory if a cache duration is not provided in the plugin response. This field is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Field                              | Description                                                                                                                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>[Required]<br>string | Required input version of the exec CredentialProviderRequest. The returned CredentialProviderResponse MUST use the same encoding version as the input. Current supported values are: <ul style="list-style-type: none"> <li>credentialprovider.kubelet.k8s.io/v1alpha1</li> </ul> |
| args<br>[]string                   | Arguments to pass to the command when executing it.                                                                                                                                                                                                                               |
| env<br>[]ExecEnvVar                | Env defines additional environment variables to expose to the process. These are unioned with the host's environment, as well as variables client-go uses to pass argument to the plugin.                                                                                         |

## ExecEnvVar

Appears in:

- [CredentialProvider](#)

ExecEnvVar is used for setting environment variables when executing an exec-based credential plugin.

- [FormatOptions](#)

JSONOptions contains options for logging format "json".

| Field                                                                               | Description                                                                             |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| OutputRoutingOptions<br>[ <b>Required</b> ]<br><a href="#">OutputRoutingOptions</a> | (Members of OutputRoutingOptions are embedded into this type.) No description provided. |

## LogFormatFactory

LogFormatFactory provides support for a certain additional, non-default log format.

## LoggingConfiguration

Appears in:

- [KubeletConfiguration](#)

LoggingConfiguration contains logging options.

| Field                                                              | Description                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| format [Required]<br>string                                        | Format Flag specifies the structure of log messages. default value of format is text                                                                                                                                                |
| flushFrequency<br>[Required]<br><a href="#">TimeOrMetaDuration</a> | Maximum time between log flushes. If a string, parsed as a duration (i.e. "1s") If an int, the maximum number of nanoseconds (i.e. 1s = 1000000000). Ignored if the selected logging backend writes log messages without buffering. |

| Field                                                             | Description                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| verbosity <b>[Required]</b><br><a href="#">VerbosityLevel</a>     | Verbosity is the threshold that determines which log messages are logged. Default is zero which logs only the most important messages. Higher values enable additional messages. Error messages are always logged.                                     |
| vmodule <b>[Required]</b><br><a href="#">VModuleConfiguration</a> | VModule overrides the verbosity threshold for individual files. Only supported for "text" log format.                                                                                                                                                  |
| options <b>[Required]</b><br><a href="#">FormatOptions</a>        | [Alpha] Options holds additional parameters that are specific to the different logging formats. Only the options for the selected format get used, but all of them get validated. Only available when the LoggingAlphaOptions feature gate is enabled. |

## LoggingOptions

LoggingOptions can be used with ValidateAndApplyWithOptions to override certain global defaults.

| Field                                                      | Description                                                |
|------------------------------------------------------------|------------------------------------------------------------|
| ErrorStream <b>[Required]</b><br><a href="#">io.Writer</a> | ErrorStream can be used to override the os.Stderr default. |
| InfoStream <b>[Required]</b><br><a href="#">io.Writer</a>  | InfoStream can be used to override the os.Stdout default.  |

## OutputRoutingOptions

Appears in:

- [JSONOptions](#)
- [TextOptions](#)

OutputRoutingOptions contains options that are supported by both "text" and "json".

| Field                                                                                                  | Description                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| splitStream <b>[Required]</b><br>bool                                                                  | [Alpha] SplitStream redirects error messages to stderr while info messages go to stdout, with buffering. The default is to write both to stdout, without buffering. Only available when the LoggingAlphaOptions feature gate is enabled. |
| infoBufferSize <b>[Required]</b><br><a href="#">k8s.io/apimachinery/pkg/api/resource.QuantityValue</a> | [Alpha] InfoBufferSize sets the size of the info stream when using split streams. The default is zero, which disables buffering.                                                                                                         |

| Field | Description                                                          |
|-------|----------------------------------------------------------------------|
|       | Only available when the LoggingAlphaOptions feature gate is enabled. |

## TextOptions

Appears in:

- [FormatOptions](#)

TextOptions contains options for logging format "text".

| Field                                                                      | Description                                                                             |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| OutputRoutingOptions<br>[Required]<br><a href="#">OutputRoutingOptions</a> | (Members of OutputRoutingOptions are embedded into this type.) No description provided. |

## TimeOrMetaDuration

Appears in:

- [LoggingConfiguration](#)

TimeOrMetaDuration is present only for backwards compatibility for the flushFrequency field, and new fields should use metav1.Duration.

| Field                                                      | Description                                                                          |
|------------------------------------------------------------|--------------------------------------------------------------------------------------|
| Duration<br>[Required]<br><a href="#">meta/v1.Duration</a> | Duration holds the duration                                                          |
| - [Required]<br>bool                                       | SerializeAsString controls whether the value is serialized as a string or an integer |

## TracingConfiguration

Appears in:

- [KubeletConfiguration](#)

TracingConfiguration provides versioned configuration for OpenTelemetry tracing clients.

| Field              | Description                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| endpoint<br>string | Endpoint of the collector this component will report traces to. The connection is insecure, and does not currently support TLS. Recommended is unset, and endpoint is the otel grpc default, localhost:4317. |

| Field                           | Description                                                                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| samplingRatePerMillion<br>int32 | SamplingRatePerMillion is the number of samples to collect per million spans. Recommended is unset. If unset, sampler respects its parent span's sampling rate, but otherwise never samples. |

## VModuleConfiguration

(Alias of `[]k8s.io/component-base/logs/api/v1.VModuleItem`)

**Appears in:**

- [LoggingConfiguration](#)

VModuleConfiguration is a collection of individual file names or patterns and the corresponding verbosity threshold.

## VerbosityLevel

(Alias of `uint32`)

**Appears in:**

- [LoggingConfiguration](#)

VerbosityLevel represents a klog or logr verbosity threshold.

## CredentialProviderConfig

CredentialProviderConfig is the configuration containing information about each exec credential provider. Kubelet reads this configuration from disk and enables each provider as specified by the CredentialProvider type.

| Field                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                                     | kubelet.config.k8s.io/v1beta1                                                                                                                                                                                                                                                                                                                                                                                  |
| kind<br>string                                                           | CredentialProviderConfig                                                                                                                                                                                                                                                                                                                                                                                       |
| providers<br>[ <b>Required</b> ]<br><a href="#">[]CredentialProvider</a> | providers is a list of credential provider plugins that will be enabled by the kubelet. Multiple providers may match against a single image, in which case credentials from all providers will be returned to the kubelet. If multiple providers are called for a single image, the results are combined. If providers return overlapping auth keys, the value from the provider earlier in this list is used. |

# KubeletConfiguration

KubeletConfiguration contains the configuration for the Kubelet

| Field                                                  | Description                                                                                                                                                                                                                               |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| apiVersion<br>string                                   | kubelet.config.k8s.io/v1beta1                                                                                                                                                                                                             |
| kind<br>string                                         | KubeletConfiguration                                                                                                                                                                                                                      |
| enableServer <b>[Required]</b><br>bool                 | enableServer enables Kubelet's secured server.<br>Note: Kubelet's insecure port is controlled by the readOnlyPort option. Default: true                                                                                                   |
| staticPodPath<br>string                                | staticPodPath is the path to the directory containing local (static) pods to run, or the path to a single static pod file. Default: ""                                                                                                    |
| podLogsDir<br>string                                   | podLogsDir is a custom root directory path kubelet will use to place pod's log files. Default: "/var/log/pods/" Note: it is not recommended to use the temp folder as a log directory as it may cause unexpected behavior in many places. |
| syncFrequency<br><a href="#">meta/v1.Duration</a>      | syncFrequency is the max period between synchronizing running containers and config. Default: "1m"                                                                                                                                        |
| fileCheckFrequency<br><a href="#">meta/v1.Duration</a> | fileCheckFrequency is the duration between checking config files for new data. Default: "20s"                                                                                                                                             |
| httpCheckFrequency<br><a href="#">meta/v1.Duration</a> | httpCheckFrequency is the duration between checking http for new data. Default: "20s"                                                                                                                                                     |
| staticPodURL<br>string                                 | staticPodURL is the URL for accessing static pods to run. Default: ""                                                                                                                                                                     |
| staticPodURLHeader<br>map[string][]string              | staticPodURLHeader is a map of slices with HTTP headers to use when accessing the podURL. Default: nil                                                                                                                                    |
| address<br>string                                      | address is the IP address for the Kubelet to serve on (set to 0.0.0.0 for all interfaces). Default: "0.0.0.0"                                                                                                                             |

| Field                       | Description                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| port<br>int32               | port is the port for the Kubelet to serve on. The port number must be between 1 and 65535, inclusive. Default: 10250                                                                                                                                                                                                            |
| readOnlyPort<br>int32       | readOnlyPort is the read-only port for the Kubelet to serve on with no authentication/authorization. The port number must be between 1 and 65535, inclusive. Setting this field to 0 disables the read-only service. Default: 0 (disabled)                                                                                      |
| tlsCertFile<br>string       | tlsCertFile is the file containing x509 Certificate for HTTPS. (CA cert, if any, concatenated after server cert). If tlsCertFile and tlsPrivateKeyFile are not provided, a self-signed certificate and key are generated for the public address and saved to the directory passed to the Kubelet's --cert-dir flag. Default: "" |
| tlsPrivateKeyFile<br>string | tlsPrivateKeyFile is the file containing x509 private key matching tlsCertFile. Default: ""                                                                                                                                                                                                                                     |
| tlsCipherSuites<br>[]string | tlsCipherSuites is the list of allowed cipher suites for the server. Note that TLS 1.3 ciphersuites are not configurable. Values are from tls package constants ( <a href="https://golang.org/pkg/crypto/tls/#pkg-constants">https://golang.org/pkg/crypto/tls/#pkg-constants</a> ). Default: nil                               |
| tlsMinVersion<br>string     | tlsMinVersion is the minimum TLS version supported. Values are from tls package constants ( <a href="https://golang.org/pkg/crypto/tls/#pkg-constants">https://golang.org/pkg/crypto/tls/#pkg-constants</a> ). Default: ""                                                                                                      |
| rotateCertificates<br>bool  | rotateCertificates enables client certificate rotation. The Kubelet will request a new certificate from the certificates.k8s.io API. This requires an approver to approve the certificate signing requests. Default: false                                                                                                      |
| serverTLSBootstrap<br>bool  | serverTLSBootstrap enables server certificate bootstrap. Instead of self signing a serving certificate, the Kubelet will request a certificate from the 'certificates.k8s.io' API. This requires an approver to approve the certificate signing requests (CSR). The RotateKubeletServerCertificate                              |

| Field                                                   | Description                                                                                                                                                                                                                                                          |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                         | feature must be enabled when setting this field.<br>Default: false                                                                                                                                                                                                   |
| authentication<br><a href="#">KubeletAuthentication</a> | authentication specifies how requests to the Kubelet's server are authenticated. Defaults: anonymous: enabled: false webhook: enabled: true cacheTTL: "2m"                                                                                                           |
| authorization<br><a href="#">KubeletAuthorization</a>   | authorization specifies how requests to the Kubelet's server are authorized. Defaults: mode: Webhook webhook: cacheAuthorizedTTL: "5m" cacheUnauthorizedTTL: "30s"                                                                                                   |
| registryPullQPS<br>int32                                | registryPullQPS is the limit of registry pulls per second. The value must not be a negative number. Setting it to 0 means no limit. Default: 5                                                                                                                       |
| registryBurst<br>int32                                  | registryBurst is the maximum size of bursty pulls, temporarily allows pulls to burst to this number, while still not exceeding registryPullQPS. The value must not be a negative number. Only used if registryPullQPS is greater than 0. Default: 10                 |
| eventRecordQPS<br>int32                                 | eventRecordQPS is the maximum event creations per second. If 0, there is no limit enforced. The value cannot be a negative number. Default: 50                                                                                                                       |
| eventBurst<br>int32                                     | eventBurst is the maximum size of a burst of event creations, temporarily allows event creations to burst to this number, while still not exceeding eventRecordQPS. This field cannot be a negative number and it is only used when eventRecordQPS > 0. Default: 100 |
| enableDebuggingHandlers<br>bool                         | enableDebuggingHandlers enables server endpoints for log access and local running of containers and commands, including the exec, attach, logs, and portforward features. Default: true                                                                              |
| enableContentionProfiling<br>bool                       | enableContentionProfiling enables block profiling, if enableDebuggingHandlers is true. Default: false                                                                                                                                                                |

| Field                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| healthzPort<br>int32                                               | healthzPort is the port of the localhost healthz endpoint (set to 0 to disable). A valid number is between 1 and 65535. Default: 10248                                                                                                                                                                                                                                                                                        |
| healthzBindAddress<br>string                                       | healthzBindAddress is the IP address for the healthz server to serve on. Default: "127.0.0.1"                                                                                                                                                                                                                                                                                                                                 |
| oomScoreAdj<br>int32                                               | oomScoreAdj is The oom-score-adj value for kubelet process. Values must be within the range [-1000, 1000]. Default: -999                                                                                                                                                                                                                                                                                                      |
| clusterDomain<br>string                                            | clusterDomain is the DNS domain for this cluster. If set, kubelet will configure all containers to search this domain in addition to the host's search domains. Default: ""                                                                                                                                                                                                                                                   |
| clusterDNS<br>[]string                                             | clusterDNS is a list of IP addresses for the cluster DNS server. If set, kubelet will configure all containers to use this for DNS resolution instead of the host's DNS servers. Default: nil                                                                                                                                                                                                                                 |
| streamingConnectionIdleTimeout<br><a href="#">meta/v1.Duration</a> | streamingConnectionIdleTimeout is the maximum time a streaming connection can be idle before the connection is automatically closed. Default: "4h"                                                                                                                                                                                                                                                                            |
| nodeStatusUpdateFrequency<br><a href="#">meta/v1.Duration</a>      | nodeStatusUpdateFrequency is the frequency that kubelet computes node status. If node lease feature is not enabled, it is also the frequency that kubelet posts node status to master. Note: When node lease feature is not enabled, be cautious when changing the constant, it must work with nodeMonitorGracePeriod in nodecontroller. Default: "10s"                                                                       |
| nodeStatusReportFrequency<br><a href="#">meta/v1.Duration</a>      | nodeStatusReportFrequency is the frequency that kubelet posts node status to master if node status does not change. Kubelet will ignore this frequency and post node status immediately if any change is detected. It is only used when node lease feature is enabled. nodeStatusReportFrequency's default value is 5m. But if nodeStatusUpdateFrequency is set explicitly, nodeStatusReportFrequency's default value will be |

| Field                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                       | set to nodeStatusUpdateFrequency for backward compatibility. Default: "5m"                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| nodeLeaseDurationSeconds<br>int32                     | nodeLeaseDurationSeconds is the duration the Kubelet will set on its corresponding Lease. NodeLease provides an indicator of node health by having the Kubelet create and periodically renew a lease, named after the node, in the kube-node-lease namespace. If the lease expires, the node can be considered unhealthy. The lease is currently renewed every 10s, per KEP-0009. In the future, the lease renewal interval may be set based on the lease duration. The field value must be greater than 0. Default: 40 |
| imageMinimumGCAge<br><a href="#">meta/v1.Duration</a> | imageMinimumGCAge is the minimum age for an unused image before it is garbage collected. Default: "2m"                                                                                                                                                                                                                                                                                                                                                                                                                  |
| imageMaximumGCAge<br><a href="#">meta/v1.Duration</a> | imageMaximumGCAge is the maximum age an image can be unused before it is garbage collected. The default of this field is "0s", which disables this field--meaning images won't be garbage collected based on being unused for too long. Default: "0s" (disabled)                                                                                                                                                                                                                                                        |
| imageGCHighThresholdPercent<br>int32                  | imageGCHighThresholdPercent is the percent of disk usage after which image garbage collection is always run. The percent is calculated by dividing this field value by 100, so this field must be between 0 and 100, inclusive. When specified, the value must be greater than imageGCLowThresholdPercent. Default: 85                                                                                                                                                                                                  |
| imageGCLowThresholdPercent<br>int32                   | imageGCLowThresholdPercent is the percent of disk usage before which image garbage collection is never run. Lowest disk usage to garbage collect to. The percent is calculated by dividing this field value by 100, so the field value must be between 0 and 100, inclusive. When specified, the value must be less than imageGCHighThresholdPercent. Default: 80                                                                                                                                                       |

| Field                                                    | Description                                                                                                                                                                                                                                                         |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| volumeStatsAggPeriod<br><a href="#">meta/v1.Duration</a> | volumeStatsAggPeriod is the frequency for calculating and caching volume disk usage for all pods. Default: "1m"                                                                                                                                                     |
| kubeletCgroups<br>string                                 | kubeletCgroups is the absolute name of cgroups to isolate the kubelet in Default: ""                                                                                                                                                                                |
| systemCgroups<br>string                                  | systemCgroups is absolute name of cgroups in which to place all non-kernel processes that are not already in a container. Empty for no container. Rolling back the flag requires a reboot. The cgroupRoot must be specified if this field is not empty. Default: "" |
| cgroupRoot<br>string                                     | cgroupRoot is the root cgroup to use for pods. This is handled by the container runtime on a best effort basis.                                                                                                                                                     |
| cgroupsPerQOS<br>bool                                    | cgroupsPerQOS enable QoS based CGroup hierarchy: top level CGroups for QoS classes and all Burstable and BestEffort Pods are brought up under their specific top level QoS CGroup. Default: true                                                                    |
| cgroupDriver<br>string                                   | cgroupDriver is the driver kubelet uses to manipulate CGroups on the host (cgroupfs or systemd). Default: "cgroupfs"                                                                                                                                                |
| cpuManagerPolicy<br>string                               | cpuManagerPolicy is the name of the policy to use. Requires the CPUManager feature gate to be enabled. Default: "None"                                                                                                                                              |
| cpuManagerPolicyOptions<br>map[string]string             | cpuManagerPolicyOptions is a set of key=value which allows to set extra options to fine tune the behaviour of the cpu manager policies. Requires both the "CPUManager" and "CPUManagerPolicyOptions" feature gates to be enabled. Default: nil                      |

| Field                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cpuManagerReconcilePeriod<br><a href="#">meta/v1.Duration</a> | cpuManagerReconcilePeriod is the reconciliation period for the CPU Manager. Requires the CPUManager feature gate to be enabled. Default: "10s"                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| memoryManagerPolicy<br>string                                 | memoryManagerPolicy is the name of the policy to use by memory manager. Requires the MemoryManager feature gate to be enabled. Default: "none"                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| topologyManagerPolicy<br>string                               | <p>topologyManagerPolicy is the name of the topology manager policy to use. Valid values include:</p> <ul style="list-style-type: none"> <li>• restricted: kubelet only allows pods with optimal NUMA node alignment for requested resources;</li> <li>• best-effort: kubelet will favor pods with NUMA alignment of CPU and device resources;</li> <li>• none: kubelet has no knowledge of NUMA alignment of a pod's CPU and device resources.</li> <li>• single-numa-node: kubelet only allows pods with a single NUMA alignment of CPU and device resources.</li> </ul> <p>Default: "none"</p> |
| topologyManagerScope<br>string                                | <p>topologyManagerScope represents the scope of topology hint generation that topology manager requests and hint providers generate. Valid values include:</p> <ul style="list-style-type: none"> <li>• container: topology policy is applied on a per-container basis.</li> <li>• pod: topology policy is applied on a per-pod basis.</li> </ul> <p>Default: "container"</p>                                                                                                                                                                                                                     |
| topologyManagerPolicyOptions<br>map[string]string             | TopologyManagerPolicyOptions is a set of key=value which allows to set extra options to fine tune the behaviour of the topology manager policies. Requires both the "TopologyManager" and "TopologyManagerPolicyOptions" feature gates to be enabled. Default: nil                                                                                                                                                                                                                                                                                                                                |

| Field                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| qosReserved<br>map[string]string                          | qosReserved is a set of resource name to percentage pairs that specify the minimum percentage of a resource reserved for exclusive use by the guaranteed QoS tier. Currently supported resources: "memory" Requires the QOSReserved feature gate to be enabled. Default: nil                                                                                                                                                                                                                                                                                                                                                                                                        |
| runtimeRequestTimeout<br><a href="#">meta/v1.Duration</a> | runtimeRequestTimeout is the timeout for all runtime requests except long running requests - pull, logs, exec and attach. Default: "2m"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| hairpinMode<br>string                                     | <p>hairpinMode specifies how the Kubelet should configure the container bridge for hairpin packets. Setting this flag allows endpoints in a Service to loadbalance back to themselves if they should try to access their own Service. Values:</p> <ul style="list-style-type: none"> <li>• "promiscuous-bridge": make the container bridge promiscuous.</li> <li>• "hairpin-veth": set the hairpin flag on container veth interfaces.</li> <li>• "none": do nothing.</li> </ul> <p>Generally, one must set --hairpin-mode=hairpin-veth to achieve hairpin NAT, because promiscuous-bridge assumes the existence of a container bridge named cbr0. Default: "promiscuous-bridge"</p> |
| maxPods<br>int32                                          | maxPods is the maximum number of Pods that can run on this Kubelet. The value must be a non-negative integer. Default: 110                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| podCIDR<br>string                                         | podCIDR is the CIDR to use for pod IP addresses, only used in standalone mode. In cluster mode, this is obtained from the control plane. Default: ""                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| podPidsLimit<br>int64                                     | podPidsLimit is the maximum number of PIDs in any pod. Default: -1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Field                                                 | Description                                                                                                                                                                                                                            |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| resolvConf<br>string                                  | resolvConf is the resolver configuration file used as the basis for the container DNS resolution configuration. If set to the empty string, will override the default and effectively disable DNS lookups. Default: "/etc/resolv.conf" |
| runOnce<br>bool                                       | runOnce causes the Kubelet to check the API server once for pods, run those in addition to the pods specified by static pod files, and exit. Default: false                                                                            |
| cpuCFSQuota<br>bool                                   | cpuCFSQuota enables CPU CFS quota enforcement for containers that specify CPU limits. Default: true                                                                                                                                    |
| cpuCFSQuotaPeriod<br><a href="#">meta/v1.Duration</a> | cpuCFSQuotaPeriod is the CPU CFS quota period value, cpu.cfs_period_us. The value must be between 1 ms and 1 second, inclusive. Requires the CustomCPUCFSQuotaPeriod feature gate to be enabled. Default: "100ms"                      |
| nodeStatusMaxImages<br>int32                          | nodeStatusMaxImages caps the number of images reported in Node.status.images. The value must be greater than -2. Note: If -1 is specified, no cap will be applied. If 0 is specified, no image is returned. Default: 50                |
| maxOpenFiles<br>int64                                 | maxOpenFiles is Number of files that can be opened by Kubelet process. The value must be a non-negative number. Default: 1000000                                                                                                       |
| contentType<br>string                                 | contentType is contentType of requests sent to apiserver. Default: "application/vnd.kubernetes.protobuf"                                                                                                                               |
| kubeAPIQPS<br>int32                                   | kubeAPIQPS is the QPS to use while talking with kubernetes apiserver. Default: 50                                                                                                                                                      |
| kubeAPIBurst<br>int32                                 | kubeAPIBurst is the burst to allow while talking with kubernetes API server. This field cannot be a negative number. Default: 100                                                                                                      |

| Field                                                                           | Description                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>serializeImagePulls</p> <p>bool</p>                                          | <p>serializeImagePulls when enabled, tells the Kubelet to pull images one at a time. We recommend <i>not</i> changing the default value on nodes that run docker daemon with version &lt; 1.9 or an Aufs storage backend. Issue #10959 has more details. Default: true</p>                                                             |
| <p>maxParallelImagePulls</p> <p>int32</p>                                       | <p>MaxParallelImagePulls sets the maximum number of image pulls in parallel. This field cannot be set if SerializeImagePulls is true. Setting it to nil means no limit. Default: nil</p>                                                                                                                                               |
| <p>evictionHard</p> <p>map[string]string</p>                                    | <p>evictionHard is a map of signal names to quantities that defines hard eviction thresholds. For example: {"memory.available": "300Mi"}. To explicitly disable, pass a 0% or 100% threshold on an arbitrary resource. Default: memory.available: "100Mi" nodefs.available: "10%" nodefs.inodesFree: "5%" imagefs.available: "15%"</p> |
| <p>evictionSoft</p> <p>map[string]string</p>                                    | <p>evictionSoft is a map of signal names to quantities that defines soft eviction thresholds. For example: {"memory.available": "300Mi"}. Default: nil</p>                                                                                                                                                                             |
| <p>evictionSoftGracePeriod</p> <p>map[string]string</p>                         | <p>evictionSoftGracePeriod is a map of signal names to quantities that defines grace periods for each soft eviction signal. For example: {"memory.available": "30s"}. Default: nil</p>                                                                                                                                                 |
| <p>evictionPressureTransitionPeriod</p> <p><a href="#">meta/v1.Duration</a></p> | <p>evictionPressureTransitionPeriod is the duration for which the kubelet has to wait before transitioning out of an eviction pressure condition. Default: "5m"</p>                                                                                                                                                                    |

| Field                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| evictionMaxPodGracePeriod<br>int32          | evictionMaxPodGracePeriod is the maximum allowed grace period (in seconds) to use when terminating pods in response to a soft eviction threshold being met. This value effectively caps the Pod's terminationGracePeriodSeconds value during soft evictions. Note: Due to issue #64530, the behavior has a bug where this value currently just overrides the grace period during soft eviction, which can increase the grace period from what is set on the Pod. This bug will be fixed in a future release. Default: 0 |
| evictionMinimumReclaim<br>map[string]string | evictionMinimumReclaim is a map of signal names to quantities that defines minimum reclaims, which describe the minimum amount of a given resource the kubelet will reclaim when performing a pod eviction while that resource is under pressure. For example: {"imagefs.available": "2Gi"}. Default: nil                                                                                                                                                                                                               |
| podsPerCore<br>int32                        | podsPerCore is the maximum number of pods per core. Cannot exceed maxPods. The value must be a non-negative integer. If 0, there is no limit on the number of Pods. Default: 0                                                                                                                                                                                                                                                                                                                                          |
| enableControllerAttachDetach<br>bool        | enableControllerAttachDetach enables the Attach/Detach controller to manage attachment/detachment of volumes scheduled to this node, and disables kubelet from executing any attach/detach operations. Note: attaching/detaching CSI volumes is not supported by the kubelet, so this option needs to be true for that use case. Default: true                                                                                                                                                                          |
| protectKernelDefaults<br>bool               | protectKernelDefaults, if true, causes the Kubelet to error if kernel flags are not as it expects. Otherwise the Kubelet will attempt to modify kernel flags to match its expectation. Default: false                                                                                                                                                                                                                                                                                                                   |
| makeIPTablesUtilChains<br>bool              | makeIPTablesUtilChains, if true, causes the Kubelet to create the KUBE-IPTABLES-HINT chain in iptables as a hint to other components about the configuration of iptables on the system. Default: true                                                                                                                                                                                                                                                                                                                   |
| iptablesMasqueradeBit<br>int32              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Field                                                           | Description                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                 | iptablesMasqueradeBit formerly controlled the creation of the KUBE-MARK-MASQ chain. Deprecated: no longer has any effect. Default: 14                                                                                                                                                                        |
| iptablesDropBit<br>int32                                        | iptablesDropBit formerly controlled the creation of the KUBE-MARK-DROP chain. Deprecated: no longer has any effect. Default: 15                                                                                                                                                                              |
| featureGates<br>map[string]bool                                 | featureGates is a map of feature names to bools that enable or disable experimental features. This field modifies piecemeal the built-in default values from "k8s.io/kubernetes/pkg/features/kube_features.go". Default: nil                                                                                 |
| failSwapOn<br>bool                                              | failSwapOn tells the Kubelet to fail to start if swap is enabled on the node. Default: true                                                                                                                                                                                                                  |
| memorySwap<br><a href="#">MemorySwapConfiguration</a>           | memorySwap configures swap memory available to container workloads.                                                                                                                                                                                                                                          |
| containerLogMaxSize<br>string                                   | containerLogMaxSize is a quantity defining the maximum size of the container log file before it is rotated. For example: "5Mi" or "256Ki". Default: "10Mi"                                                                                                                                                   |
| containerLogMaxFiles<br>int32                                   | containerLogMaxFiles specifies the maximum number of container log files that can be present for a container. Default: 5                                                                                                                                                                                     |
| containerLogMaxWorkers<br>int32                                 | ContainerLogMaxWorkers specifies the maximum number of concurrent workers to spawn for performing the log rotate operations. Set this count to 1 for disabling the concurrent log rotation workflows Default: 1                                                                                              |
| containerLogMonitorInterval<br><a href="#">meta/v1.Duration</a> | ContainerLogMonitorInterval specifies the duration at which the container logs are monitored for performing the log rotate operation. This defaults to 10 * time.Seconds. But can be customized to a smaller value based on the log generation rate and the size required to be rotated against Default: 10s |

| Field                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>configMapAndSecretChangeDetectionStrategy</code><br><a href="#">ResourceChangeDetectionStrategy</a> | <p><code>configMapAndSecretChangeDetectionStrategy</code> is a mode in which ConfigMap and Secret managers are running. Valid values include:</p> <ul style="list-style-type: none"> <li>• Get: kubelet fetches necessary objects directly from the API server;</li> <li>• Cache: kubelet uses TTL cache for object fetched from the API server;</li> <li>• Watch: kubelet uses watches to observe changes to objects that are in its interest.</li> </ul> <p>Default: "Watch"</p>                   |
| <code>systemReserved</code><br><code>map[string]string</code>                                             | <p><code>systemReserved</code> is a set of <code>ResourceName=ResourceQuantity</code> (e.g. <code>cpu=200m,memory=150G</code>) pairs that describe resources reserved for non-kubernetes components. Currently only cpu and memory are supported. See <a href="http://kubernetes.io/docs/user-guide/compute-resources">http://kubernetes.io/docs/user-guide/compute-resources</a> for more detail. Default: nil</p>                                                                                  |
| <code>kubeReserved</code><br><code>map[string]string</code>                                               | <p><code>kubeReserved</code> is a set of <code>ResourceName=ResourceQuantity</code> (e.g. <code>cpu=200m,memory=150G</code>) pairs that describe resources reserved for kubernetes system components. Currently cpu, memory and local storage for root file system are supported. See <a href="https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/">https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/</a> for more details. Default: nil</p> |
| <code>reservedSystemCPUs</code> <b>[Required]</b><br><code>string</code>                                  | <p>The <code>reservedSystemCPUs</code> option specifies the CPU list reserved for the host level system threads and kubernetes related threads. This provide a "static" CPU list rather than the "dynamic" list by <code>systemReserved</code> and <code>kubeReserved</code>. This option does not support <code>systemReservedCgroup</code> or <code>kubeReservedCgroup</code>.</p>                                                                                                                 |
| <code>showHiddenMetricsForVersion</code><br><code>string</code>                                           | <p><code>showHiddenMetricsForVersion</code> is the previous version for which you want to show hidden metrics. Only the previous minor version is meaningful, other values will not be allowed. The format is <code>&lt;major&gt;.&lt;minor&gt;</code>, e.g.: 1.16. The purpose of this format is make sure you have the opportunity to notice if the next release hides</p>                                                                                                                         |

| Field                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
