| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm init phase kubelet-start

This phase will write the kubelet configuration file and environment file and then start the kubelet.

- [kubelet-start](#)

Write kubelet settings and (re)start the kubelet

### Synopsis

Write a file with KubeletConfiguration and an environment file with node specific kubelet settings, and then (re)start kubelet.

```
kubeadm init phase kubelet-start [flags]
```

### Examples

```
Writes a dynamic environment file with kubelet flags from a InitConfiguration file.
kubeadm init phase kubelet-start --config config.yaml
```

### Options

|                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --config string                                                                                                                                                                              |
| Path to a kubeadm configuration file.                                                                                                                                                        |
| --cri-socket string                                                                                                                                                                          |
| Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |
| --dry-run                                                                                                                                                                                    |
| Don't apply any changes; just output what would be done.                                                                                                                                     |
| -h, --help                                                                                                                                                                                   |
| help for kubelet-start                                                                                                                                                                       |

| Specify the node name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

Generate all certificates

## Synopsis

Generate all certificates

kubeadm init phase certs all [flags]

## Options

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used.                 |
| --apiserver-cert-extra-sans strings                                                                                                    |
| Optional extra Subject Alternative Names (SANs) to use for the API Server serving certificate. Can be both IP addresses and DNS names. |
| --cert-dir string   Default: "/etc/kubernetes/pki"                                                                                     |
| The path where to save and store the certificates.                                                                                     |
| --config string                                                                                                                        |
| Path to a kubeadm configuration file.                                                                                                  |
| --control-plane-endpoint string                                                                                                        |
| Specify a stable IP address or DNS name for the control plane.                                                                         |
| --dry-run                                                                                                                              |
| Don't apply any changes; just output what would be done.                                                                               |

Generate the certificate for serving the Kubernetes API

## Synopsis

Generate the certificate for serving the Kubernetes API, and save them into apiserver.crt and apiserver.key files.

If both files already exist, kubeadm skips the generation step and existing files will be used.

kubeadm init phase certs apiserver [flags]

## Options

|                                      |
|--------------------------------------|
| --apiserver-advertise-address string |
|--------------------------------------|

|                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------|
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
|------------------------------------------------------------------------------------------------------------------------|

|                                     |
|-------------------------------------|
| --apiserver-cert-extra-sans strings |
|-------------------------------------|

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| Optional extra Subject Alternative Names (SANs) to use for the API Server serving certificate. Can be both IP addresses and DNS names. |
|----------------------------------------------------------------------------------------------------------------------------------------|

|                                                    |
|----------------------------------------------------|
| --cert-dir string   Default: "/etc/kubernetes/pki" |
|----------------------------------------------------|

|                                                    |
|----------------------------------------------------|
| The path where to save and store the certificates. |
|----------------------------------------------------|

|                 |
|-----------------|
| --config string |
|-----------------|

|                                       |
|---------------------------------------|
| Path to a kubeadm configuration file. |
|---------------------------------------|

|                 | [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generate the certificate for etcd nodes to communicate with each other

## Synopsis

Generate the certificate for etcd nodes to communicate with each other, and save them into etcd/peer.crt and etcd/peer.key files.

Default SANs are localhost, 127.0.0.1, 127.0.0.1, ::1

If both files already exist, kubeadm skips the generation step and existing files will be used.

```
kubeadm init phase certs etcd-peer [flags]
```

## Options

|                   |                                                    |
|-------------------|----------------------------------------------------|
| --cert-dir string | Default: "/etc/kubernetes/pki"                     |
|                   | The path where to save and store the certificates. |
| --config string   |                                                    |
|                   | Path to a kubeadm configuration file.              |
| --dry-run         |                                                    |

|                                                             |
|-------------------------------------------------------------|
| Don't apply any changes; just output what would be done.    |
| -h, --help                                                  |
| help for etcd-peer                                          |
| --kubernetes-version string    Default: "stable-1"          |
| Choose a specific Kubernetes version for the control plane. |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generate the certificate for liveness probes to healthcheck etcd

## Synopsis

Generate the certificate for liveness probes to healthcheck etcd, and save them into etcd/healthcheck-client.crt and etcd/healthcheck-client.key files.

If both files already exist, kubeadm skips the generation step and existing files will be used.

```
kubeadm init phase certs etcd-healthcheck-client [flags]
```

## Options

|                                                             |
|-------------------------------------------------------------|
| --cert-dir string    Default: "/etc/kubernetes/pki"         |
| The path where to save and store the certificates.          |
| --config string                                             |
| Path to a kubeadm configuration file.                       |
| --dry-run                                                   |
| Don't apply any changes; just output what would be done.    |
| -h, --help                                                  |
| help for etcd-healthcheck-client                            |
| --kubernetes-version string    Default: "stable-1"          |
| Choose a specific Kubernetes version for the control plane. |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generate the certificate the apiserver uses to access etcd

## Synopsis

Generate the certificate the apiserver uses to access etcd, and save them into apiserver-etcd-client.crt and apiserver-etcd-client.key files.

If both files already exist, kubeadm skips the generation step and existing files will be used.

kubeadm init phase certs apiserver-etcd-client [flags]

## Options

|                                                             |                                |
|-------------------------------------------------------------|--------------------------------|
| --cert-dir string                                           | Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates.          |                                |
| --config string                                             |                                |
| Path to a kubeadm configuration file.                       |                                |
| --dry-run                                                   |                                |

Generate a private key for signing service account tokens along with its public key

## Synopsis

Generate the private key for signing service account tokens along with its public key, and save them into sa.key and sa.pub files.

If both files already exist, kubeadm skips the generation step and existing files will be used.

```
kubeadm init phase certs sa [flags]
```

## Options

|                                                    |                                |
|----------------------------------------------------|--------------------------------|
| --cert-dir string                                  | Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates. |                                |
| -h, --help                                         |                                |
| help for sa                                        |                                |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm init phase kubeconfig

You can create all required kubeconfig files by calling the all subcommand or call them individually.

- [kubeconfig](#)
- [all](#)
- [admin](#)
- [kubelet](#)
- [controller-manager](#)
- [scheduler](#)
- [super-admin](#)

Generate all kubeconfig files necessary to establish the control plane and the admin kubeconfig file

## Synopsis

This command is not meant to be run on its own. See list of available subcommands.

```
kubeadm init phase kubeconfig [flags]
```

## Options

|                     |
|---------------------|
| -h, --help          |
| help for kubeconfig |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generate all kubeconfig files

## Synopsis

Generate all kubeconfig files

kubeadm init phase kubeconfig all [flags]

## Options

|                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| --apiserver-bind-port int32    Default: 6443                                                                           |
| Port for the API Server to bind to.                                                                                    |
| --cert-dir string    Default: "/etc/kubernetes/pki"                                                                    |
| The path where to save and store the certificates.                                                                     |
| --config string                                                                                                        |
| Path to a kubeadm configuration file.                                                                                  |
| --control-plane-endpoint string                                                                                        |
| Specify a stable IP address or DNS name for the control plane.                                                         |
| --dry-run                                                                                                              |
| Don't apply any changes; just output what would be done.                                                               |
| -h, --help                                                                                                             |

Generate a kubeconfig file for the kubelet to use *only* for cluster bootstrapping purposes

## Synopsis

Generate the kubeconfig file for the kubelet to use and save it to kubelet.conf file.

Please note that this should *only* be used for cluster bootstrapping purposes. After your control plane is up, you should request all kubelet credentials from the CSR API.

```
kubeadm init phase kubeconfig kubelet [flags]
```

## Options

|                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| --apiserver-bind-port int32    Default: 6443                                                                           |
| Port for the API Server to bind to.                                                                                    |
| --cert-dir string    Default: "/etc/kubernetes/pki"                                                                    |

|                                                                 |                                                                |
|-----------------------------------------------------------------|----------------------------------------------------------------|
|                                                                 | The path where to save and store the certificates.             |
| <code>--config string</code>                                    |                                                                |
|                                                                 | Path to a kubeadm configuration file.                          |
| <code>--control-plane-endpoint string</code>                    |                                                                |

## kubeadm init phase control-plane

Using this phase you can create all required static Pod files for the control plane components.

- [control-plane](#)
- [all](#)
- [apiserver](#)
- [controller-manager](#)
- [scheduler](#)

Generate all static Pod manifest files necessary to establish the control plane

### Synopsis

This command is not meant to be run on its own. See list of available subcommands.

```
kubeadm init phase control-plane [flags]
```

### Options

Generate all static Pod manifest files

### Synopsis

Generate all static Pod manifest files

```
kubeadm init phase control-plane all [flags]
```

### Examples

```
Generates all static Pod manifest files for control plane components,
functionally equivalent to what is generated by kubeadm init.
kubeadm init phase control-plane all
```

```
Generates all static Pod manifest files using options read from a configuration file.
kubeadm init phase control-plane all --config config.yaml
```

## Options

|                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--apiserver-advertise-address</code> string                                                                                                                                                                                                                                                                                                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used.                                                                                                                                                                                                                                                                                              |
| <code>--apiserver-bind-port</code> int32    Default: 6443                                                                                                                                                                                                                                                                                                                                                           |
| Port for the API Server to bind to.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>--apiserver-extra-args</code> <comma-separated 'key=value' pairs>                                                                                                                                                                                                                                                                                                                                             |
| A set of extra flags to pass to the API Server or override default ones in form of <flagname>=<value>                                                                                                                                                                                                                                                                                                               |
| <code>--cert-dir</code> string    Default: "/etc/kubernetes/pki"                                                                                                                                                                                                                                                                                                                                                    |
| The path where to save and store the certificates.                                                                                                                                                                                                                                                                                                                                                                  |
| <code>--config</code> string                                                                                                                                                                                                                                                                                                                                                                                        |

| Choose a specific Kubernetes version for the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubenetconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --pod-network-cidr string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Specify range of IP addresses for the pod network. If set, the control plane will automatically allocate CIDRs for every node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| --scheduler-extra-args <comma-separated 'key=value' pairs>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| A set of extra flags to pass to the Scheduler or override default ones in form of <flagname>=<value>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Choose a specific Kubernetes version for the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>--patches string</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| <b>--service-cidr string</b> Default: "10.96.0.0/12"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Use alternative range of IP address for service VIPs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Options inherited from parent commands

|-------------------------------------------------------------|
| <b>--rootfs string</b>                                      |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generates the kube-controller-manager static Pod manifest

## Synopsis

Generates the kube-controller-manager static Pod manifest

kubeadm init phase control-plane controller-manager [flags]

## Options

|                                                                                                               |
|---------------------------------------------------------------------------------------------------------------|
| <b>--cert-dir string</b> Default: "/etc/kubernetes/pki"                                                       |
| The path where to save and store the certificates.                                                            |
| <b>--config string</b>                                                                                        |
| Path to a kubeadm configuration file.                                                                         |
| <b>--controller-manager-extra-args &lt;comma-separated 'key=value' pairs&gt;</b>                              |
| A set of extra flags to pass to the Controller Manager or override default ones in form of <flagname>=<value> |
| <b>--dry-run</b>                                                                                              |
| Don't apply any changes; just output what would be done.                                                      |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Choose a container registry to pull control plane images from                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --kubernetes-version string   Default: "stable-1"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Choose a specific Kubernetes version for the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --pod-network-cidr string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Specify range of IP addresses for the pod network. If set, the control plane will automatically allocate CIDRs for every node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generates the kube-scheduler static Pod manifest

## Synopsis

Generates the kube-scheduler static Pod manifest

kubeadm init phase control-plane scheduler [flags]

## Options

|                                                    |
|----------------------------------------------------|
| --cert-dir string   Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates. |
| --config string                                    |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a kubeadm configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| --dry-run                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Don't apply any changes; just output what would be done.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Choose a container registry to pull control plane images from                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --kubernetes-version string    Default: "stable-1"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Choose a specific Kubernetes version for the control plane.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubenetconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --scheduler-extra-args <comma-separated 'key=value' pairs>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| A set of extra flags to pass to the Scheduler or override default ones in form of <flagname>=<value>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm init phase etcd

Use the following phase to create a local etcd instance based on a static Pod file.

- [etcd](#)
- [local](#)

Generate static Pod manifest file for local etcd

## Synopsis

This command is not meant to be run on its own. See list of available subcommands.

```
kubeadm init phase etcd [flags]
```

## Options

|               |
|---------------|
| -h, --help    |
| help for etcd |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Generate the static Pod manifest file for a local, single-node local etcd instance

## Synopsis

Generate the static Pod manifest file for a local, single-node local etcd instance

```
kubeadm init phase etcd local [flags]
```

## Examples

```
Generates the static Pod manifest file for etcd, functionally
equivalent to what is generated by kubeadm init.
kubeadm init phase etcd local

Generates the static Pod manifest file for etcd using options
read from a configuration file.
kubeadm init phase etcd local --config config.yaml
```

## Options

|                                                    |                                |
|----------------------------------------------------|--------------------------------|
| --cert-dir string                                  | Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates. |                                |
| --config string                                    |                                |
| Path to a kubeadm configuration file.              |                                |
| --dry-run                                          |                                |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Don't apply any changes; just output what would be done.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

Upload the kubeadm ClusterConfiguration to a ConfigMap

## Synopsis

Upload the kubeadm ClusterConfiguration to a ConfigMap called kubeadm-config in the kube-system namespace. This enables correct configuration of system components and a seamless user experience when upgrading.

Alternatively, you can use kubeadm config.

```
kubeadm init phase upload-config kubeadm [flags]
```

## Examples

```
upload the configuration of your cluster
kubeadm init phase upload-config --config=myConfig.yaml
```

## Options

|                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --config string                                                                                                                                                                              |
| Path to a kubeadm configuration file.                                                                                                                                                        |
| --cri-socket string                                                                                                                                                                          |
| Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |

Upload the kubelet component config to a ConfigMap

## Synopsis

Upload the kubelet configuration extracted from the kubeadm InitConfiguration object to a kubelet-config ConfigMap in the cluster

```
kubeadm init phase upload-config kubelet [flags]
```

## Examples

```
Upload the kubelet configuration from the kubeadm Config file to a ConfigMap in the cluster.
```

```
kubeadm init phase upload-config kubelet --config kubeadm.yaml
```

## Options

|                     |                                                                                                                                                                                              |

## kubeadm init phase upload-certs

Use the following phase to upload control-plane certificates to the cluster. By default the certs and encryption key expire after two hours.

- [upload-certs](#)

Upload certificates to kubeadm-certs

Synopsis

Upload control plane certificates to the kubeadm-certs Secret

kubeadm init phase upload-certs [flags]

Options

|                                                             |                                                                                                                                                                  |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --certificate-key string                                    | Key used to encrypt the control-plane certificates in the kubeadm-certs Secret. The certificate key is a hex encoded string that is an AES key of size 32 bytes. |
| --config string                                             | Path to a kubeadm configuration file.                                                                                                                            |
| --dry-run                                                   | Don't apply any changes; just output what would be done.                                                                                                         |
| -h, --help                                                  | help for upload-certs                                                                                                                                            |
| --kubeconfig string   Default: "/etc/kubernetes/admin.conf" | The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file.     |
| --skip-certificate-key-print                                | Don't print the key used to encrypt the control-plane certificates.                                                                                              |
| --upload-certs                                              | Upload control-plane certificates to the kubeadm-certs Secret.                                                                                                   |

Options inherited from parent commands

|                 |                                                             |
|-----------------|-------------------------------------------------------------|
| --rootfs string | [EXPERIMENTAL] The path to the 'real' host root filesystem. |

# kubeadm init phase mark-control-plane

Use the following phase to label and taint the node as a control plane node.

- [mark-control-plane](#)

Mark a node as a control-plane

## Synopsis

Mark a node as a control-plane

```
kubeadm init phase mark-control-plane [flags]
```

## Examples

```
Applies control-plane label and taint to the current node, functionally equivalent to what
executed by kubeadm init.
kubeadm init phase mark-control-plane --config config.yaml

Applies control-plane label and taint to a specific node
kubeadm init phase mark-control-plane --node-name myNode
```

## Options

|                                                          |
|----------------------------------------------------------|
| --config string                                          |
| Path to a kubeadm configuration file.                    |
| --dry-run                                                |
| Don't apply any changes; just output what would be done. |
| -h, --help                                               |
| help for mark-control-plane                              |
| --node-name string                                       |
| Specify the node name.                                   |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

# kubeadm init phase bootstrap-token

Use the following phase to configure bootstrap tokens.

- [bootstrap-token](#)

Generates bootstrap tokens used to join a node to a cluster

## Synopsis

Bootstrap tokens are used for establishing bidirectional trust between a node joining the cluster and a control-plane node.

This command makes all the configurations required to make bootstrap tokens works and then creates an initial token.

```
kubeadm init phase bootstrap-token [flags]
```

## Examples

```
Make all the bootstrap token configurations and create an initial token, functionally
equivalent to what generated by kubeadm init.
kubeadm init phase bootstrap-token
```

## Options

|                     |                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --config string     |                                                                                                                                                              |
|                     | Path to a kubeadm configuration file.                                                                                                                        |
| --dry-run           |                                                                                                                                                              |
|                     | Don't apply any changes; just output what would be done.                                                                                                     |
| -h, --help          |                                                                                                                                                              |
|                     | help for bootstrap-token                                                                                                                                     |
| --kubeconfig string | Default: "/etc/kubernetes/admin.conf"                                                                                                                        |
|                     | The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --skip-token-print  |                                                                                                                                                              |
|                     | Skip printing of the default bootstrap token generated by 'kubeadm init'.                                                                                    |

## kubeadm init phase kubelet-finalize

Use the following phase to update settings relevant to the kubelet after TLS bootstrap. You can use the all subcommand to run all kubelet-finalize phases.

- [kubelet-finalize](#)
- [kubelet-finalize-all](#)
- [kubelet-finalize-cert-rotation](#)

Updates settings relevant to the kubelet after TLS bootstrap

### Synopsis

Updates settings relevant to the kubelet after TLS bootstrap

```
kubeadm init phase kubelet-finalize [flags]
```

### Examples

```
Updates settings relevant to the kubelet after TLS bootstrap"
kubeadm init phase kubelet-finalize all --config
```

### Options

|                           |
|---------------------------|
| -h, --help                |
| help for kubelet-finalize |

### Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Run all kubelet-finalize phases

### Synopsis

Run all kubelet-finalize phases

```
kubeadm init phase kubelet-finalize all [flags]
```

## Examples

```
Updates settings relevant to the kubelet after TLS bootstrap"
kubeadm init phase kubelet-finalize all --config
```

## Options

|                                                          |                                |
|----------------------------------------------------------|--------------------------------|
| --cert-dir string                                        | Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates.       |                                |
| --config string                                          |                                |
| Path to a kubeadm configuration file.                    |                                |
| --dry-run                                                |                                |
| Don't apply any changes; just output what would be done. |                                |
| -h, --help                                               |                                |

| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm init phase addon

You can install all the available addons with the `all` subcommand, or install them selectively.

- [addon](#)
- [all](#)
- [coredns](#)
- [kube-proxy](#)

Install required addons for passing conformance tests

## Synopsis

This command is not meant to be run on its own. See list of available subcommands.

```
kubeadm init phase addon [flags]
```

## Options

|                |
|----------------|
| -h, --help     |
| help for addon |

|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Install all the addons

## Synopsis

Install all the addons

kubeadm init phase addon all [flags]

## Options

|                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                         | The IP address the API Server will advertise it's listening on. If not set the default network interface will be used.                                                                                                                                                                                                                                                                                              |
| --apiserver-bind-port int32    Default: 6443                 | Port for the API Server to bind to.                                                                                                                                                                                                                                                                                                                                                                                 |
| --config string                                              | Path to a kubeadm configuration file.                                                                                                                                                                                                                                                                                                                                                                               |
| --control-plane-endpoint string                              | Specify a stable IP address or DNS name for the control plane.                                                                                                                                                                                                                                                                                                                                                      |
| --dry-run                                                    | Don't apply any changes; just output what would be done.                                                                                                                                                                                                                                                                                                                                                            |
| --feature-gates string                                       | A set of key=value pairs that describe feature gates for various features. Options are:<br>EtcdLearnerMode=true false (BETA - default=true)<br>PublicKeysECDSA=true false (DEPRECATED - default=false)<br>RootlessControlPlane=true false (ALPHA - default=false)<br>UpgradeAddonsBeforeControlPlane=true false (DEPRECATED - default=false)<br>WaitForAllControlPlaneComponents=true false (ALPHA - default=false) |
| -h, --help                                                   | help for all                                                                                                                                                                                                                                                                                                                                                                                                        |
| --image-repository string    Default: "registry.k8s.io"      | Choose a container registry to pull control plane images from                                                                                                                                                                                                                                                                                                                                                       |
| --kubeconfig string    Default: "/etc/kubernetes/admin.conf" | The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file.                                                                                                                                                                                                                                                        |
| --kubernetes-version string    Default: "stable-1"           | Choose a specific Kubernetes version for the control plane.                                                                                                                                                                                                                                                                                                                                                         |
| --pod-network-cidr string                                    |                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------|
| Specify range of IP addresses for the pod network. If set, the control plane will automatically allocate CIDRs for every node. |
| --service-cidr string    Default: "10.96.0.0/12"                                                                               |
| Use alternative range of IP address for service VIPs.                                                                          |
| --service-dns-domain string    Default: "cluster.local"                                                                        |
| Use alternative domain for services, e.g. "myorg.internal".                                                                    |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Install the CoreDNS addon to a Kubernetes cluster

## Synopsis

Install the CoreDNS addon components via the API server. Please note that although the DNS server is deployed, it will not be scheduled until CNI is installed.

```
kubeadm init phase addon coredns [flags]
```

## Options

|                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --config string                                                                                                                                                                                                                                                                                                                                                                                                     |
| Path to a kubeadm configuration file.                                                                                                                                                                                                                                                                                                                                                                               |
| --dry-run                                                                                                                                                                                                                                                                                                                                                                                                           |
| Don't apply any changes; just output what would be done.                                                                                                                                                                                                                                                                                                                                                            |

|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Install the kube-proxy addon to a Kubernetes cluster

## Synopsis

Install the kube-proxy addon components via the API server.

```
kubeadm init phase addon kube-proxy [flags]
```

## Options

|                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| --apiserver-bind-port int32     Default: 6443                                                                          |
| Port for the API Server to bind to.                                                                                    |

|                                                                                                                                                              |

|                                                             |
|-------------------------------------------------------------|
| <code>--rootfs string</code>                                |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

For more details on each field in the v1beta3 configuration you can navigate to our [API reference pages](#).

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster
- [kubeadm reset](#) to revert any changes made to this host by kubeadm init or kubeadm join
- [kubeadm alpha](#) to try experimental functionality

## kubeadm join phase

kubeadm join phase enables you to invoke atomic steps of the join process. Hence, you can let kubeadm do some of the work and you can fill in the gaps if you wish to apply customization.

kubeadm join phase is consistent with the [kubeadm join workflow](#), and behind the scene both use the same code.

## kubeadm join phase

- [phase](#)

Use this command to invoke single phase of the join workflow

### Synopsis

Use this command to invoke single phase of the join workflow

### Options

|                |
|----------------|
| -h, --help     |
| help for phase |

### Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm join phase preflight

Using this phase you can execute preflight checks on a joining node.

- [preflight](#)

Run join pre-flight checks

## Synopsis

Run pre-flight checks for kubeadm join.

```
kubeadm join phase preflight [api-server-endpoint] [flags]
```

## Examples

```
Run join pre-flight checks using a config file.
kubeadm join phase preflight --config kubeadm-config.yaml
```

## Options

|                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--apiserver-advertise-address</code> string                                                                                                                                            |
| If the node should host a new control plane instance, the IP address the API Server will advertise it's listening on. If not set the default network interface will be used.                 |
| <code>--apiserver-bind-port</code> int32    Default: 6443                                                                                                                                    |
| If the node should host a new control plane instance, the port for the API Server to bind to.                                                                                                |
| <code>--certificate-key</code> string                                                                                                                                                        |
| Use this key to decrypt the certificate secrets uploaded by init. The certificate key is a hex encoded string that is an AES key of size 32 bytes.                                           |
| <code>--config</code> string                                                                                                                                                                 |
| Path to a kubeadm configuration file.                                                                                                                                                        |
| <code>--control-plane</code>                                                                                                                                                                 |
| Create a new control plane instance on this node                                                                                                                                             |
| <code>--cri-socket</code> string                                                                                                                                                             |
| Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |
| <code>--discovery-file</code> string                                                                                                                                                         |
| For file-based discovery, a file or URL from which to load cluster information.                                                                                                              |
| <code>--discovery-token</code> string                                                                                                                                                        |
| For token-based discovery, the token used to validate cluster information fetched from the API server.                                                                                       |
| <code>--discovery-token-ca-cert-hash</code> strings                                                                                                                                          |

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| For token-based discovery, validate that the root CA public key matches this hash (format: "<type>:<value>").                          |
| --discovery-token-unsafe-skip-ca-verification                                                                                          |
| For token-based discovery, allow joining without --discovery-token-ca-cert-hash pinning.                                               |
| --dry-run                                                                                                                              |
| Don't apply any changes; just output what would be done.                                                                               |
| -h, --help                                                                                                                             |
| help for preflight                                                                                                                     |
| --ignore-preflight-errors strings                                                                                                      |
| A list of checks whose errors will be shown as warnings. Example: 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks. |
| --node-name string                                                                                                                     |
| Specify the node name.                                                                                                                 |
| --tls-bootstrap-token string                                                                                                           |
| Specify the token used to temporarily authenticate with the Kubernetes Control Plane while joining the node.                           |
| --token string                                                                                                                         |
| Use this token for both discovery-token and tls-bootstrap-token when those values are not provided.                                    |

|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm join phase control-plane-prepare

Using this phase you can prepare a node for serving a control-plane.

- [control-plane-prepare](#)

- [download-certs](#)
- [certs](#)

- [kubeconfig](#)
- [control-plane](#)

Prepare the machine for serving a control plane

## Synopsis

Prepare the machine for serving a control plane

```
kubeadm join phase control-plane-prepare [flags]
```

## Examples

```
Prepares the machine for serving a control plane
kubeadm join phase control-plane-prepare all
```

## Options

|                                |
|--------------------------------|
| -h, --help                     |
| help for control-plane-prepare |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Prepare the machine for serving a control plane

## Synopsis

Prepare the machine for serving a control plane

```
kubeadm join phase control-plane-prepare all [api-server-endpoint] [flags]
```

## Options

|                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                                                                         |
| If the node should host a new control plane instance, the IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| --apiserver-bind-port int32   Default: 6443                                                                                                                                  |
| If the node should host a new control plane instance, the port for the API Server to bind to.                                                                                |

| --node-name string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Specify the node name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubenetconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --tls-bootstrap-token string                                                                                 |
| Specify the token used to temporarily authenticate with the Kubernetes Control Plane while joining the node. |
| --token string                                                                                               |
| Use this token for both discovery-token and tls-bootstrap-token when those values are not provided.          |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

[EXPERIMENTAL] Download certificates shared among control-plane nodes from the kubeadm-certs Secret

## Synopsis

[EXPERIMENTAL] Download certificates shared among control-plane nodes from the kubeadm-certs Secret

kubeadm join phase control-plane-prepare download-certs [api-server-endpoint] [flags]

## Options

|                                                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------|
| --certificate-key string                                                                                                                           |
| Use this key to decrypt the certificate secrets uploaded by init. The certificate key is a hex encoded string that is an AES key of size 32 bytes. |
| --config string                                                                                                                                    |
| Path to a kubeadm configuration file.                                                                                                              |
| --control-plane                                                                                                                                    |
| Create a new control plane instance on this node                                                                                                   |
| --discovery-file string                                                                                                                            |
| For file-based discovery, a file or URL from which to load cluster information.                                                                    |
| --discovery-token string                                                                                                                           |
| For token-based discovery, the token used to validate cluster information fetched from the API server.                                             |

|                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------|
| <code>--discovery-token-ca-cert-hash</code> strings                                                                           |
| For token-based discovery, validate that the root CA public key matches this hash (format: "<type>:<value>").                 |
| <code>--discovery-token-unsafe-skip-ca-verification</code>                                                                    |
| For token-based discovery, allow joining without <code>--discovery-token-ca-cert-hash</code> pinning.                         |
| <code>--dry-run</code>                                                                                                        |
| Don't apply any changes; just output what would be done.                                                                      |
| <code>-h, --help</code>                                                                                                       |
| help for download-certs                                                                                                       |
| <code>--tls-bootstrap-token</code> string                                                                                     |
| Specify the token used to temporarily authenticate with the Kubernetes Control Plane while joining the node.                  |
| <code>--token</code> string                                                                                                   |
| Use this token for both <code>discovery-token</code> and <code>tls-bootstrap-token</code> when those values are not provided. |

Generate the certificates for the new control plane components

## Synopsis

Generate the certificates for the new control plane components

```
kubeadm join phase control-plane-prepare certs [api-server-endpoint] [flags]
```

## Options

|                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--apiserver-advertise-address</code> string                                                                                                                            |
| If the node should host a new control plane instance, the IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| <code>--config</code> string                                                                                                                                                 |

|                                                            |                                                                                                                                          |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
|                                                            | Path to a kubeadm configuration file.                                                                                                    |
| <code>--control-plane</code>                               |                                                                                                                                          |
|                                                            | Create a new control plane instance on this node                                                                                         |
| <code>--discovery-file</code> string                       |                                                                                                                                          |

| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm join phase kubelet-start

Using this phase you can write the kubelet settings, certificates and (re)start the kubelet.

- [kubelet-start](#)

Write kubelet settings, certificates and (re)start the kubelet

### Synopsis

Write a file with KubeletConfiguration and an environment file with node specific kubelet settings, and then (re)start kubelet.

```
kubeadm join phase kubelet-start [api-server-endpoint] [flags]
```

### Options

|                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --config string                                                                                                                                                                              |
| Path to a kubeadm configuration file.                                                                                                                                                        |
| --cri-socket string                                                                                                                                                                          |
| Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |
| --discovery-file string                                                                                                                                                                      |

|  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|  | Path to a directory that contains files named " <code>target[suffix][+patchtype].extension</code> ". For example, " <code>kube-apiserver0+merge.yaml</code> " or just " <code>etcd.json</code> ". " <code>target</code> " can be one of " <code>kube-apiserver</code> ", " <code>kube-controller-manager</code> ", " <code>kube-scheduler</code> ", " <code>etcd</code> ", " <code>kubeletconfiguration</code> ". " <code>patchtype</code> " can be one of " <code>strategic</code> ", " <code>merge</code> " or " <code>json</code> " and they match the patch formats supported by kubectl. The default " <code>patchtype</code> " is " <code>strategic</code> ". " <code>extension</code> " must be either " <code>json</code> " or " <code>yaml</code> ". " <code>suffix</code> " is an optional string that can be used to determine which patches are applied first alpha-numerically. |

## kubeadm join phase control-plane-join

Using this phase you can join a node as a control-plane instance.

- [control-plane-join](#)
- [all](#)
- [etcd](#)
- [update-status](#)
- [mark-control-plane](#)

Join a machine as a control plane instance

### Synopsis

Join a machine as a control plane instance

```
kubeadm join phase control-plane-join [flags]
```

### Examples

```
Joins a machine as a control plane instance
kubeadm join phase control-plane-join all
```

### Options

|                             |
|-----------------------------|
| -h, --help                  |
| help for control-plane-join |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Join a machine as a control plane instance

### Synopsis

Join a machine as a control plane instance

```
kubeadm join phase control-plane-join all [flags]
```

|                                      | Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubenetconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

|                                      | Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubenetconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

Mark a node as a control-plane

Synopsis

Mark a node as a control-plane

kubeadm join phase control-plane-join mark-control-plane [flags]

Options

|                                                  |
|--------------------------------------------------|
| --config string                                  |
| Path to a kubeadm configuration file.            |
| --control-plane                                  |
| Create a new control plane instance on this node |

|                                                          |
|----------------------------------------------------------|
| --dry-run                                                |
| Don't apply any changes; just output what would be done. |
| -h, --help                                               |
| help for mark-control-plane                              |
| --node-name string                                       |
| Specify the node name.                                   |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster
- [kubeadm reset](#) to revert any changes made to this host by kubeadm init or kubeadm join
- [kubeadm alpha](#) to try experimental functionality

# kubeadm kubeconfig

kubeadm kubeconfig provides utilities for managing kubeconfig files.

For examples on how to use kubeadm kubeconfig user see [Generating kubeconfig files for additional users](#).

## kubeadm kubeconfig

- [overview](#)

Kubeconfig file utilities

### Synopsis

Kubeconfig file utilities.

### Options

|            |
|------------|
| -h, --help |
|------------|

|                     |
|---------------------|
| help for kubeconfig |
|---------------------|

## Options inherited from parent commands

|                 |
|-----------------|
| --rootfs string |
|-----------------|

|                                                             |
|-------------------------------------------------------------|
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |
|-------------------------------------------------------------|

## kubeadm kubeconfig user

This command can be used to output a kubeconfig file for an additional user.

- [user](#)

Output a kubeconfig file for an additional user

### Synopsis

Output a kubeconfig file for an additional user.

```
kubeadm kubeconfig user [flags]
```

### Examples

```
Output a kubeconfig file for an additional user named foo
kubeadm kubeconfig user --client-name=foo
```

```
Output a kubeconfig file for an additional user named foo using a kubeadm config file bar
kubeadm kubeconfig user --client-name=foo --config=bar
```

### Options

|                      |
|----------------------|
| --client-name string |
|----------------------|

|                                                                                |
|--------------------------------------------------------------------------------|
| The name of user. It will be used as the CN if client certificates are created |
|--------------------------------------------------------------------------------|

|                 |
|-----------------|
| --config string |
|-----------------|

|                                       |
|---------------------------------------|
| Path to a kubeadm configuration file. |
|---------------------------------------|

|            |
|------------|
| -h, --help |
|------------|

|               |
|---------------|
| help for user |
|---------------|

|               |
|---------------|
| --org strings |
|---------------|

|                                                                                                                   |
|-------------------------------------------------------------------------------------------------------------------|
| The organizations of the client certificate. It will be used as the O if client certificates are created          |
| --token string                                                                                                    |
| The token that should be used as the authentication mechanism for this kubeconfig, instead of client certificates |
| --validity-period duration    Default: 8760h0m0s                                                                  |
| The validity period of the client certificate. It is an offset from the current time.                             |

### Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm reset phase

kubeadm reset phase enables you to invoke atomic steps of the node reset process. Hence, you can let kubeadm do some of the work and you can fill in the gaps if you wish to apply customization.

kubeadm reset phase is consistent with the [kubeadm reset workflow](#), and behind the scene both use the same code.

## kubeadm reset phase

- [phase](#)

Use this command to invoke single phase of the reset workflow

### Synopsis

Use this command to invoke single phase of the reset workflow

### Options

|                |
|----------------|
| -h, --help     |
| help for phase |

### Options inherited from parent commands

|                 |
|-----------------|
| --rootfs string |
|-----------------|

|                                                             |
|-------------------------------------------------------------|
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |
|-------------------------------------------------------------|

## kubeadm reset phase preflight

Using this phase you can execute preflight checks on a node that is being reset.

- [preflight](#)

Run reset pre-flight checks

### Synopsis

Run pre-flight checks for kubeadm reset.

```
kubeadm reset phase preflight [flags]
```

### Options

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| --dry-run                                                                                                                              |
| Don't apply any changes; just output what would be done.                                                                               |
| -f, --force                                                                                                                            |
| Reset the node without prompting for confirmation.                                                                                     |
| -h, --help                                                                                                                             |
| help for preflight                                                                                                                     |
| --ignore-preflight-errors strings                                                                                                      |
| A list of checks whose errors will be shown as warnings. Example: 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks. |

### Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm reset phase remove-etcd-member

Using this phase you can remove this control-plane node's etcd member from the etcd cluster.

- [remove-etcd-member](#)

Remove a local etcd member.

## Synopsis

Remove a local etcd member for a control plane node.

```
kubeadm reset phase remove-etcd-member [flags]
```

## Options

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--dry-run</code>                                                                                                                                       |
| Don't apply any changes; just output what would be done.                                                                                                     |
| <code>-h, --help</code>                                                                                                                                      |
| help for remove-etcd-member                                                                                                                                  |
| <code>--kubeconfig string</code> Default: <code>"/etc/kubernetes/admin.conf"</code>                                                                          |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| <code>--rootfs string</code>                                |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm reset phase cleanup-node

Using this phase you can perform cleanup on this node.

- [cleanup-node](#)

Run cleanup node.

## Synopsis

Run cleanup node.

```
kubeadm reset phase cleanup-node [flags]
```

## Options

|                                                                                                  |
|--------------------------------------------------------------------------------------------------|
| <code>--cert-dir string</code> Default: <code>"/etc/kubernetes/pki"</code>                       |
| The path to the directory where the certificates are stored. If specified, clean this directory. |

|                                                                                                                                                                                              |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--cleanup-tmp-dir</code>                                                                                                                                                               |
| Cleanup the <code>"/etc/kubernetes/tmp"</code> directory                                                                                                                                     |
| <code>--cri-socket string</code>                                                                                                                                                             |
| Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |
| <code>--dry-run</code>                                                                                                                                                                       |
| Don't apply any changes; just output what would be done.                                                                                                                                     |
| <code>-h, --help</code>                                                                                                                                                                      |
| help for cleanup-node                                                                                                                                                                        |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| <code>--rootfs string</code>                                |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster
- [kubeadm reset](#) to revert any changes made to this host by `kubeadm init` or `kubeadm join`
- [kubeadm alpha](#) to try experimental functionality

# kubeadm upgrade phase

In v1.15.0, kubeadm introduced preliminary support for kubeadm upgrade node phases. Phases for other kubeadm upgrade sub-commands such as `apply`, could be added in the following releases.

## kubeadm upgrade node phase

Using this phase you can choose to execute the separate steps of the upgrade of secondary control-plane or worker nodes. Please note that `kubeadm upgrade apply` still has to be called on a primary control-plane node.

- [phase](#)
- [preflight](#)
- [control-plane](#)
- [kubelet-config](#)

Use this command to invoke single phase of the node workflow

## Synopsis

Use this command to invoke single phase of the node workflow

## Options

|                |
|----------------|
| -h, --help     |
| help for phase |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Run upgrade node pre-flight checks

## Synopsis

Run pre-flight checks for kubeadm upgrade node.

kubeadm upgrade node phase preflight [flags]

## Options

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| -h, --help                                                                                                                             |

| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file.                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                       |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                       |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |                                       |

Options inherited from parent commands

|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Upgrade the kubelet configuration for this node

Synopsis

Download the kubelet configuration from the kubelet-config ConfigMap stored in the cluster

kubeadm upgrade node phase kubelet-config [flags]

## Options

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <code>--dry-run</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Do not change any state, just output the actions that would be performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-h, --help</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| help for kubelet-config                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>--kubeconfig string</code> Default: "/etc/kubernetes/admin.conf"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>--patches string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| <code>--rootfs string</code>                                |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster
- [kubeadm reset](#) to revert any changes made to this host by kubeadm init or kubeadm join
- [kubeadm upgrade](#) to upgrade a kubeadm node
- [kubeadm alpha](#) to try experimental functionality

## Implementation details

FEATURE STATE: Kubernetes v1.10 [stable]

kubeadm init and kubeadm join together provide a nice user experience for creating a bare Kubernetes cluster from scratch, that aligns with the best-practices. However, it might not be obvious *how* kubeadm does that.

This document provides additional details on what happens under the hood, with the aim of sharing knowledge on the best practices for a Kubernetes cluster.

## Core design principles

The cluster that kubeadm init and kubeadm join set up should be:

- **Secure:** It should adopt latest best-practices like:
  - enforcing RBAC
  - using the Node Authorizer
  - using secure communication between the control plane components
  - using secure communication between the API server and the kubelets
  - lock-down the kubelet API
  - locking down access to the API for system components like the kube-proxy and CoreDNS
  - locking down what a Bootstrap Token can access
- **User-friendly:** The user should not have to run anything more than a couple of commands:
  - kubeadm init
  - export KUBECONFIG=/etc/kubernetes/admin.conf
  - kubectl apply -f <network-of-choice.yaml>
  - kubeadm join --token <token> <endpoint>:<port>
- **Extendable:**
  - It should *not* favor any particular network provider. Configuring the cluster network is out-of-scope
  - It should provide the possibility to use a config file for customizing various parameters

## Constants and well-known values and paths

In order to reduce complexity and to simplify development of higher level tools that build on top of kubeadm, it uses a limited set of constant values for well-known paths and file names.

The Kubernetes directory /etc/kubernetes is a constant in the application, since it is clearly the given path in a majority of cases, and the most intuitive location; other constant paths and file names are:

- /etc/kubernetes/manifests as the path where the kubelet should look for static Pod manifests. Names of static Pod manifests are:
  - etcd.yaml
  - kube-apiserver.yaml
  - kube-controller-manager.yaml
  - kube-scheduler.yaml
- /etc/kubernetes/ as the path where kubeconfig files with identities for control plane components are stored. Names of kubeconfig files are:
  - kubelet.conf (bootstrap-kubelet.conf during TLS bootstrap)
  - controller-manager.conf
  - scheduler.conf
  - admin.conf for the cluster admin and kubeadm itself

- super-admin.conf for the cluster super-admin that can bypass RBAC
- Names of certificates and key files:
  - ca.crt, ca.key for the Kubernetes certificate authority
  - apiserver.crt, apiserver.key for the API server certificate
  - apiserver-kubelet-client.crt, apiserver-kubelet-client.key for the client certificate used by the API server to connect to the kubelets securely
  - sa.pub, sa.key for the key used by the controller manager when signing ServiceAccount
  - front-proxy-ca.crt, front-proxy-ca.key for the front proxy certificate authority
  - front-proxy-client.crt, front-proxy-client.key for the front proxy client

## kubeadm init workflow internal design

The kubeadm init consists of a sequence of atomic work tasks to perform, as described in the kubeadm init [internal workflow](#).

The [kubeadm init phase](#) command allows users to invoke each task individually, and ultimately offers a reusable and composable API/toolbox that can be used by other Kubernetes bootstrap tools, by any IT automation tool or by an advanced user for creating custom clusters.

### Preflight checks

Kubeadm executes a set of preflight checks before starting the init, with the aim to verify preconditions and avoid common cluster startup problems. The user can skip specific preflight checks or all of them with the --ignore-preflight-errors option.

- [Warning] if the Kubernetes version to use (specified with the --kubernetes-version flag) is at least one minor version higher than the kubeadm CLI version.
- Kubernetes system requirements:
  - if running on linux:
    - [Error] if Kernel is older than the minimum required version
    - [Error] if required cgroups subsystem aren't set up
- [Error] if the CRI endpoint does not answer
- [Error] if user is not root
- [Error] if the machine hostname is not a valid DNS subdomain
- [Warning] if the host name cannot be reached via network lookup
- [Error] if kubelet version is lower than the minimum kubelet version supported by kubeadm (current minor -1)
- [Error] if kubelet version is at least one minor higher than the required controlplane version (unsupported version skew)
- [Warning] if kubelet service does not exist or if it is disabled
- [Warning] if firewalld is active
- [Error] if API server bindPort or ports 10250/10251/10252 are used
- [Error] if /etc/kubernetes/manifest folder already exists and it is not empty
- [Error] if swap is on
- [Error] if conntrack, ip, iptables, mount, nsenter commands are not present in the command path
- [Warning] if ebtables, ethtool, socat, tc, touch, crictl commands are not present in the command path

- [Warning] if extra arg flags for API server, controller manager, scheduler contains some invalid options
- [Warning] if connection to `https://API.AdvertiseAddress:API.BindPort` goes through proxy
- [Warning] if connection to services subnet goes through proxy (only first address checked)
- [Warning] if connection to Pods subnet goes through proxy (only first address checked)
- If external etcd is provided:
  - [Error] if etcd version is older than the minimum required version
  - [Error] if etcd certificates or keys are specified, but not provided
- If external etcd is NOT provided (and thus local etcd will be installed):
  - [Error] if ports 2379 is used
  - [Error] if `EtcdataDir` folder already exists and it is not empty
- If authorization mode is ABAC:
  - [Error] if `abac_policy.json` does not exist
- If authorization mode is WebHook
  - [Error] if `webhook_authz.conf` does not exist

#### Note:

Preflight checks can be invoked individually with the [kubeadm init phase preflight](#) command.

## Generate the necessary certificates

Kubeadm generates certificate and private key pairs for different purposes:

- A self signed certificate authority for the Kubernetes cluster saved into `ca.crt` file and `ca.key` private key file
- A serving certificate for the API server, generated using `ca.crt` as the CA, and saved into `apiserver.crt` file with its private key `apiserver.key`. This certificate should contain the following alternative names:
  - The Kubernetes service's internal clusterIP (the first address in the services CIDR, e.g. 10.96.0.1 if service subnet is 10.96.0.0/12)
  - Kubernetes DNS names, e.g. `kubernetes.default.svc.cluster.local` if `--service-dns-domain` flag value is `cluster.local`, plus default DNS names `kubernetes.default.svc`, `kubernetes.default`, `kubernetes`
  - The node-name
  - The `--apiserver-advertise-address`
  - Additional alternative names specified by the user
- A client certificate for the API server to connect to the kubelets securely, generated using `ca.crt` as the CA and saved into `apiserver-kubelet-client.crt` file with its private key `apiserver-kubelet-client.key`. This certificate should be in the `system:masters` organization
- A private key for signing ServiceAccount Tokens saved into `sa.key` file along with its public key `sa.pub`
- A certificate authority for the front proxy saved into `front-proxy-ca.crt` file with its key `front-proxy-ca.key`

- A client certificate for the front proxy client, generated using front-proxy-ca.crt as the CA and saved into front-proxy-client.crt file with its private key front-proxy-client.key

Certificates are stored by default in /etc/kubernetes/pki, but this directory is configurable using the `--cert-dir` flag.

Please note that:

1. If a given certificate and private key pair both exist, and their content is evaluated to be compliant with the above specs, the existing files will be used and the generation phase for the given certificate will be skipped. This means the user can, for example, copy an existing CA to /etc/kubernetes/pki/ca.{crt,key}, and then kubeadm will use those files for signing the rest of the certs. See also [using custom certificates](#)
2. For the CA, it is possible to provide the ca.crt file but not the ca.key file. If all other certificates and kubeconfig files are already in place, kubeadm recognizes this condition and activates the ExternalCA, which also implies the csr signer controller in controller-manager won't be started
3. If kubeadm is running in [external CA mode](#); all the certificates must be provided by the user, because kubeadm cannot generate them by itself
4. In case kubeadm is executed in the `--dry-run` mode, certificate files are written in a temporary folder
5. Certificate generation can be invoked individually with the [kubeadm init phase certs all](#) command

## Generate kubeconfig files for control plane components

Kubeadm generates kubeconfig files with identities for control plane components:

- A kubeconfig file for the kubelet to use during TLS bootstrap - /etc/kubernetes/bootstrap-kubelet.conf. Inside this file, there is a bootstrap-token or embedded client certificates for authenticating this node with the cluster.

This client certificate should:

- Be in the system:nodes organization, as required by the [Node Authorization](#) module
- Have the Common Name (CN) system:node:<hostname-lowercased>
- A kubeconfig file for controller-manager, /etc/kubernetes/controller-manager.conf; inside this file is embedded a client certificate with controller-manager identity. This client certificate should have the CN system:kube-controller-manager, as defined by default [RBAC core components roles](#)
- A kubeconfig file for scheduler, /etc/kubernetes/scheduler.conf; inside this file is embedded a client certificate with scheduler identity. This client certificate should have the CN system:kube-scheduler, as defined by default [RBAC core components roles](#)

Additionally, a kubeconfig file for kubeadm as an administrative entity is generated and stored in /etc/kubernetes/admin.conf. This file includes a certificate with Subject: O = kubeadm:cluster-admins, CN = kubernet-admin. kubeadm:cluster-admins is a group managed by kubeadm. It is bound to the cluster-admin ClusterRole during kubeadm init, by using the super-admin.conf file, which does not require RBAC. This admin.conf file must remain on control plane nodes and should not be shared with additional users.

During kubeadm init another kubeconfig file is generated and stored in `/etc/kubernetes/super-admin.conf`. This file includes a certificate with Subject: O = system:masters, CN = kubernetes-super-admin. system:masters is a superuser group that bypasses RBAC and makes super-admin.conf useful in case of an emergency where a cluster is locked due to RBAC misconfiguration. The super-admin.conf file must be stored in a safe location and should not be shared with additional users.

See [RBAC user facing role bindings](#) for additional information on RBAC and built-in ClusterRoles and groups.

Please note that:

1. ca.crt certificate is embedded in all the kubeconfig files.
2. If a given kubeconfig file exists, and its content is evaluated as compliant with the above specs, the existing file will be used and the generation phase for the given kubeconfig will be skipped
3. If kubeadm is running in [ExternalCA mode](#), all the required kubeconfig must be provided by the user as well, because kubeadm cannot generate any of them by itself
4. In case kubeadm is executed in the `--dry-run` mode, kubeconfig files are written in a temporary folder
5. Generation of kubeconfig files can be invoked individually with the [kubeadm init phase kubeconfig all](#) command

## Generate static Pod manifests for control plane components

Kubeadm writes static Pod manifest files for control plane components to `/etc/kubernetes/manifests`. The kubelet watches this directory for Pods to be created on startup.

Static Pod manifests share a set of common properties:

- All static Pods are deployed on kube-system namespace
- All static Pods get tier:control-plane and component:{component-name} labels
- All static Pods use the system-node-critical priority class
- `hostNetwork: true` is set on all static Pods to allow control plane startup before a network is configured; as a consequence:
  - The address that the controller-manager and the scheduler use to refer to the API server is 127.0.0.1
  - If the etcd server is set up locally, the etcd-server address will be set to 127.0.0.1:2379
- Leader election is enabled for both the controller-manager and the scheduler
- Controller-manager and the scheduler will reference kubeconfig files with their respective, unique identities
- All static Pods get any extra flags specified by the user as described in [passing custom arguments to control plane components](#)
- All static Pods get any extra Volumes specified by the user (Host path)

Please note that:

1. All images will be pulled from registry.k8s.io by default. See [using custom images](#) for customizing the image repository
2. In case kubeadm is executed in the `--dry-run` mode, static Pod files are written in a temporary folder
3. Static Pod manifest generation for control plane components can be invoked individually with the [kubeadm init phase control-plane all](#) command

## API server

The static Pod manifest for the API server is affected by the following parameters provided by the users:

- The `apiserver-advertise-address` and `apiserver-bind-port` to bind to; if not provided, those values default to the IP address of the default network interface on the machine and port 6443
- The `service-cluster-ip-range` to use for services
- If an external etcd server is specified, the `etcd-servers` address and related TLS settings (`etcd-cafile`, `etcd-certfile`, `etcd-keyfile`); if an external etcd server is not provided, a local etcd will be used (via host network)
- If a cloud provider is specified, the corresponding `--cloud-provider` parameter is configured together with the `--cloud-config` path if such file exists (this is experimental, alpha and will be removed in a future version)

Other API server flags that are set unconditionally are:

- `--insecure-port=0` to avoid insecure connections to the api server
- `--enable-bootstrap-token-auth=true` to enable the BootstrapTokenAuthenticator authentication module. See [TLS Bootstrapping](#) for more details
- `--allow-privileged` to true (required e.g. by kube proxy)
- `--requestheader-client-ca-file` to `front-proxy-ca.crt`
- `--enable-admission-plugins` to:
  - [NamespaceLifecycle](#) e.g. to avoid deletion of system reserved namespaces
  - [LimitRanger](#) and [ResourceQuota](#) to enforce limits on namespaces
  - [ServiceAccount](#) to enforce service account automation
  - [PersistentVolumeLabel](#) attaches region or zone labels to PersistentVolumes as defined by the cloud provider (This admission controller is deprecated and will be removed in a future version. It is not deployed by kubeadm by default with v1.9 onwards when not explicitly opting into using gce or aws as cloud providers)
  - [DefaultStorageClass](#) to enforce default storage class on PersistentVolumeClaim objects
  - [DefaultTolerationSeconds](#)
  - [NodeRestriction](#) to limit what a kubelet can modify (e.g. only pods on this node)
- `--kubelet-preferred-address-types` to `InternalIP,ExternalIP,Hostname`; this makes kubect logs and other API server-kubelet communication work in environments where the hostnames of the nodes aren't resolvable

Flags for using certificates generated in previous steps:

- - `--client-ca-file` to `ca.crt`
  - `--tls-cert-file` to `apiserver.crt`
  - `--tls-private-key-file` to `apiserver.key`
  - `--kubelet-client-certificate` to `apiserver-kubelet-client.crt`
  - `--kubelet-client-key` to `apiserver-kubelet-client.key`
  - `--service-account-key-file` to `sa.pub`
  - `--requestheader-client-ca-file` to `front-proxy-ca.crt`
  - `--proxy-client-cert-file` to `front-proxy-client.crt`
  - `--proxy-client-key-file` to `front-proxy-client.key`
- Other flags for securing the front proxy ([API Aggregation](#)) communications:
  - `--requestheader-username-headers=X-Remote-User`
  - `--requestheader-group-headers=X-Remote-Group`
  - `--requestheader-extra-headers-prefix=X-Remote-Extra-`
  - `--requestheader-allowed-names=front-proxy-client`

## Controller manager

The static Pod manifest for the controller manager is affected by following parameters provided by the users:

- If kubeadm is invoked specifying a `--pod-network-cidr`, the subnet manager feature required for some CNI network plugins is enabled by setting:
  - `--allocate-node-cidrs=true`
  - `--cluster-cidr` and `--node-cidr-mask-size` flags according to the given CIDR
- If a cloud provider is specified, the corresponding `--cloud-provider` is specified together with the `--cloud-config` path if such configuration file exists (this is experimental, alpha and will be removed in a future version)

Other flags that are set unconditionally are:

- `--controllers` enabling all the default controllers plus BootstrapSigner and TokenCleaner controllers for TLS bootstrap. See [TLS Bootstrapping](#) for more details.
- `--use-service-account-credentials` to `true`
- Flags for using certificates generated in previous steps:
  - `--root-ca-file` to `ca.crt`
  - `--cluster-signing-cert-file` to `ca.crt`, if External CA mode is disabled, otherwise to `""`
  - `--cluster-signing-key-file` to `ca.key`, if External CA mode is disabled, otherwise to `""`
  - `--service-account-private-key-file` to `sa.key`

## Scheduler

The static Pod manifest for the scheduler is not affected by parameters provided by the users.

## Generate static Pod manifest for local etcd

If you specified an external etcd, this step will be skipped, otherwise kubeadm generates a static Pod manifest file for creating a local etcd instance running in a Pod with following attributes:

- listen on localhost:2379 and use HostNetwork=true
- make a hostPath mount out from the dataDir to the host's filesystem
- Any extra flags specified by the user

Please note that:

1. The etcd container image will be pulled from registry.gcr.io by default. See [using custom images](#) for customizing the image repository.
2. If you run kubeadm in --dry-run mode, the etcd static Pod manifest is written into a temporary folder.
3. You can directly invoke static Pod manifest generation for local etcd, using the [kubeadm init phase etcd local](#) command.

## Wait for the control plane to come up

kubeadm waits (upto 4m0s) until localhost:6443/healthz (kube-apiserver liveness) returns ok. However, in order to detect deadlock conditions, kubeadm fails fast if localhost:10255/healthz (kubelet liveness) or localhost:10255/healthz/syncloop (kubelet readiness) don't return ok within 40s and 60s respectively.

kubeadm relies on the kubelet to pull the control plane images and run them properly as static Pods. After the control plane is up, kubeadm completes the tasks described in following paragraphs.

## Save the kubeadm ClusterConfiguration in a ConfigMap for later reference

kubeadm saves the configuration passed to kubeadm init in a ConfigMap named kubeadm-config under kube-system namespace.

This will ensure that kubeadm actions executed in future (e.g kubeadm upgrade) will be able to determine the actual/current cluster state and make new decisions based on that data.

Please note that:

1. Before saving the ClusterConfiguration, sensitive information like the token is stripped from the configuration
2. Upload of control plane node configuration can be invoked individually with the command [kubeadm init phase upload-config](#).

## Mark the node as control-plane

As soon as the control plane is available, kubeadm executes the following actions:

- Labels the node as control-plane with node-role.kubernetes.io/control-plane=""
- Taints the node with node-role.kubernetes.io/control-plane:NoSchedule

Please note that the phase to mark the control-plane phase can be invoked individually with the [kubeadm init phase mark-control-plane](#) command.

## Configure TLS-Bootstrapping for node joining

Kubeadm uses [Authenticating with Bootstrap Tokens](#) for joining new nodes to an existing cluster; for more details see also [design proposal](#).

kubeadm init ensures that everything is properly configured for this process, and this includes following steps as well as setting API server and controller flags as already described in previous paragraphs.

### Note:

TLS bootstrapping for nodes can be configured with the command [kubeadm init phase bootstrap-token](#), executing all the configuration steps described in following paragraphs; alternatively, each step can be invoked individually.

### Create a bootstrap token

kubeadm init creates a first bootstrap token, either generated automatically or provided by the user with the --token flag; as documented in bootstrap token specification, token should be saved as a secret with name bootstrap-token-<token-id> under kube-system namespace.

Please note that:

1. The default token created by kubeadm init will be used to validate temporary user during TLS bootstrap process; those users will be member of system:bootstrappers:kubeadm:default-node-token group
2. The token has a limited validity, default 24 hours (the interval may be changed with the --token-ttl flag)
3. Additional tokens can be created with the [kubeadm token](#) command, that provide other useful functions for token management as well.

### Allow joining nodes to call CSR API

Kubeadm ensures that users in system:bootstrappers:kubeadm:default-node-token group are able to access the certificate signing API.

This is implemented by creating a ClusterRoleBinding named kubeadm:kubelet-bootstrap between the group above and the default RBAC role system:node-bootstrapper.

### Set up auto approval for new bootstrap tokens

Kubeadm ensures that the Bootstrap Token will get its CSR request automatically approved by the csrapprover controller.

This is implemented by creating ClusterRoleBinding named kubeadm:node-autoapprove-bootstrap between the system:bootstrappers:kubeadm:default-node-token group and the default role system:certificates.k8s.io:certificatesigningrequests:nodeclient.

The role `system:certificates.k8s.io:certificatesigningrequests:nodeclient` should be created as well, granting POST permission to `/apis/certificates.k8s.io/certificatesigningrequests/nodeclient`.

## Set up nodes certificate rotation with auto approval

Kubeadm ensures that certificate rotation is enabled for nodes, and that a new certificate request for nodes will get its CSR request automatically approved by the `csrapprover` controller.

This is implemented by creating `ClusterRoleBinding` named `kubeadm:node-autoapprove-certificate-rotation` between the `system:nodes` group and the default role `system:certificates.k8s.io:certificatesigningrequests:selfnodeclient`.

## Create the public cluster-info ConfigMap

This phase creates the `cluster-info` `ConfigMap` in the `kube-public` namespace.

Additionally, it creates a `Role` and a `RoleBinding` granting access to the `ConfigMap` for unauthenticated users (i.e. users in RBAC group `system:unauthenticated`).

### Note:

The access to the `cluster-info` `ConfigMap` *is not* rate-limited. This may or may not be a problem if you expose your cluster's API server to the internet; worst-case scenario here is a DoS attack where an attacker uses all the in-flight requests the `kube-apiserver` can handle to serve the `cluster-info` `ConfigMap`.

## Install addons

Kubeadm installs the internal DNS server and the `kube-proxy` addon components via the API server.

### Note:

This phase can be invoked individually with the command [kubeadm init phase addon all](#).

### proxy

A `ServiceAccount` for `kube-proxy` is created in the `kube-system` namespace; then `kube-proxy` is deployed as a `DaemonSet`:

- The credentials (`ca.crt` and `token`) to the control plane come from the `ServiceAccount`
- The location (URL) of the API server comes from a `ConfigMap`
- The `kube-proxy` `ServiceAccount` is bound to the privileges in the `system:node-proxier` `ClusterRole`

### DNS

- The `CoreDNS` service is named `kube-dns`. This is done to prevent any interruption in service when the user is switching the cluster DNS from `kube-dns` to `CoreDNS` through the `--config` method described [here](#).

A ServiceAccount for CoreDNS is created in the kube-system namespace.

- 
- The coredns ServiceAccount is bound to the privileges in the system:coredns ClusterRole

In Kubernetes version 1.21, support for using kube-dns with kubeadm was removed. You can use CoreDNS with kubeadm even when the related Service is named kube-dns.

## kubeadm join phases internal design

Similarly to kubeadm init, also kubeadm join internal workflow consists of a sequence of atomic work tasks to perform.

This is split into discovery (having the Node trust the Kubernetes Master) and TLS bootstrap (having the Kubernetes Master trust the Node).

see [Authenticating with Bootstrap Tokens](#) or the corresponding [design proposal](#).

### Preflight checks

kubeadm executes a set of preflight checks before starting the join, with the aim to verify preconditions and avoid common cluster startup problems.

Please note that:

1. kubeadm join preflight checks are basically a subset of kubeadm init preflight checks
2. Starting from 1.24, kubeadm uses crictl to communicate to all known CRI endpoints.
3. Starting from 1.9, kubeadm provides support for joining nodes running on Windows; in that case, linux specific controls are skipped.
4. In any case the user can skip specific preflight checks (or eventually all preflight checks) with the --ignore-preflight-errors option.

### Discovery cluster-info

There are 2 main schemes for discovery. The first is to use a shared token along with the IP address of the API server. The second is to provide a file (that is a subset of the standard kubeconfig file).

#### Shared token discovery

If kubeadm join is invoked with --discovery-token, token discovery is used; in this case the node basically retrieves the cluster CA certificates from the cluster-info ConfigMap in the kube-public namespace.

In order to prevent "man in the middle" attacks, several steps are taken:

- First, the CA certificate is retrieved via insecure connection (this is possible because kubeadm init is granted access to cluster-info users for system:unauthenticated)
- Then the CA certificate goes through following validation steps:
  - Basic validation: using the token ID against a JWT signature
  - Pub key validation: using provided --discovery-token-ca-cert-hash. This value is available in the output of kubeadm init or can be calculated using standard tools

(the hash is calculated over the bytes of the Subject Public Key Info (SPKI) object as in RFC7469). The `--discovery-token-ca-cert-hash` flag may be repeated multiple times to allow more than one public key.

- As an additional validation, the CA certificate is retrieved via secure connection and then compared with the CA retrieved initially

**Note:**

Pub key validation can be skipped passing `--discovery-token-unsafe-skip-ca-verification` flag; This weakens the kubeadm security model since others can potentially impersonate the Kubernetes Master.

## File/https discovery

If `kubeadm join` is invoked with `--discovery-file`, file discovery is used; this file can be a local file or downloaded via an HTTPS URL; in case of HTTPS, the host installed CA bundle is used to verify the connection.

With file discovery, the cluster CA certificate is provided into the file itself; in fact, the discovery file is a kubeconfig file with only server and certificate-authority-data attributes set, as described in the [kubeadm join](#) reference doc; when the connection with the cluster is established, kubeadm tries to access the cluster-info ConfigMap, and if available, uses it.

## TLS Bootstrap

Once the cluster info is known, the file `bootstrap-kubelet.conf` is written, thus allowing kubelet to do TLS Bootstrapping.

The TLS bootstrap mechanism uses the shared token to temporarily authenticate with the Kubernetes API server to submit a certificate signing request (CSR) for a locally created key pair.

The request is then automatically approved and the operation completes saving `ca.crt` file and `kubelet.conf` file to be used by the kubelet for joining the cluster, while `bootstrap-kubelet.conf` is deleted.

**Note:**

- The temporary authentication is validated against the token saved during the `kubeadm init` process (or with additional tokens created with `kubeadm token` command)
- The temporary authentication resolves to a user member of `system:bootstrappers:kubeadm:default-node-token` group which was granted access to the CSR api during the `kubeadm init` process
- The automatic CSR approval is managed by the `csrapprover` controller, according to the configuration present in the `kubeadm init` process

## Command line tool (kubectl)

Kubernetes provides a command line tool for communicating with a Kubernetes cluster's [control plane](#), using the Kubernetes API.

This tool is named `kubectl`.

For configuration, `kubectl` looks for a file named `config` in the `$HOME/.kube` directory. You can specify other [kubeconfig](#) files by setting the `KUBECONFIG` environment variable or by setting the `--kubeconfig` flag.

This overview covers `kubectl` syntax, describes the command operations, and provides common examples. For details about each command, including all the supported flags and subcommands, see the [kubectl](#) reference documentation.

For installation instructions, see [Installing kubectl](#); for a quick guide, see the [cheat sheet](#). If you're used to using the docker command-line tool, [kubectl for Docker Users](#) explains some equivalent commands for Kubernetes.

## Syntax

Use the following syntax to run `kubectl` commands from your terminal window:

```
kubectl [command] [TYPE] [NAME] [flags]
```

where `command`, `TYPE`, `NAME`, and `flags` are:

- `command`: Specifies the operation that you want to perform on one or more resources, for example `create`, `get`, `describe`, `delete`.
- `TYPE`: Specifies the [resource type](#). Resource types are case-insensitive and you can specify the singular, plural, or abbreviated forms. For example, the following commands produce the same output:

```
kubectl get pod pod1
kubectl get pods pod1
kubectl get po pod1
```

- `NAME`: Specifies the name of the resource. Names are case-sensitive. If the name is omitted, details for all resources are displayed, for example `kubectl get pods`.

When performing an operation on multiple resources, you can specify each resource by type and name or specify one or more files:

- To specify resources by type and name:
  - To group resources if they are all the same type: `TYPE1 name1 name2 name<#>`.  
Example: `kubectl get pod example-pod1 example-pod2`
  - To specify multiple resource types individually: `TYPE1/name1 TYPE1/name2 TYPE2/name3 TYPE<#>/name<#>`.  
Example: `kubectl get pod/example-pod1 replicationcontroller/example-rc1`
- To specify resources with one or more files: `-f file1 -f file2 -f file<#>`
  - [Use YAML rather than JSON](#) since YAML tends to be more user-friendly, especially for configuration files.  
Example: `kubectl get -f ./pod.yaml`

- flags: Specifies optional flags. For example, you can use the `-s` or `--server` flags to specify the address and port of the Kubernetes API server.

### Caution:

Flags that you specify from the command line override default values and any corresponding environment variables.

If you need help, run `kubectl help` from the terminal window.

## In-cluster authentication and namespace overrides

By default `kubectl` will first determine if it is running within a pod, and thus in a cluster. It starts by checking for the `KUBERNETES_SERVICE_HOST` and `KUBERNETES_SERVICE_PORT` environment variables and the existence of a service account token file at `/var/run/secrets/kubernetes.io/serviceaccount/token`. If all three are found in-cluster authentication is assumed.

To maintain backwards compatibility, if the `POD_NAMESPACE` environment variable is set during in-cluster authentication it will override the default namespace from the service account token. Any manifests or tools relying on namespace defaulting will be affected by this.

### POD\_NAMESPACE environment variable

If the `POD_NAMESPACE` environment variable is set, cli operations on namespaced resources will default to the variable value. For example, if the variable is set to `seattle`, `kubectl get pods` would return pods in the `seattle` namespace. This is because pods are a namespaced resource, and no namespace was provided in the command. Review the output of `kubectl api-resources` to determine if a resource is namespaced.

Explicit use of `--namespace <value>` overrides this behavior.

### How kubectl handles ServiceAccount tokens

If:

- there is Kubernetes service account token file mounted at `/var/run/secrets/kubernetes.io/serviceaccount/token`, and
- the `KUBERNETES_SERVICE_HOST` environment variable is set, and
- the `KUBERNETES_SERVICE_PORT` environment variable is set, and
- you don't explicitly specify a namespace on the `kubectl` command line

then `kubectl` assumes it is running in your cluster. The `kubectl` tool looks up the namespace of that `ServiceAccount` (this is the same as the namespace of the `Pod`) and acts against that namespace. This is different from what happens outside of a cluster; when `kubectl` runs outside a cluster and you don't specify a namespace, the `kubectl` command acts against the namespace set for the current context in your client configuration. To change the default namespace for your `kubectl` you can use the following command:

```
kubectl config set-context --current --namespace=<namespace-name>
```

# Operations

The following table includes short descriptions and the general syntax for all of the kubectl operations:

| Operation     | Syntax                                                                                                                                        | Description                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| alpha         | kubectl alpha SUBCOMMAND [flags]                                                                                                              | List the available commands that correspond to alpha features, which are not enabled in Kubernetes clusters by default.                               |
| annotate      | kubectl annotate (-f FILENAME   TYPE NAME   TYPE/NAME) KEY_1=VAL_1 ... KEY_N=VAL_N [--overwrite] [--all] [--resource-version=version] [flags] | Add or update the annotations of one or more resources.                                                                                               |
| api-resources | kubectl api-resources [flags]                                                                                                                 | List the API resources that are available.                                                                                                            |
| api-versions  | kubectl api-versions [flags]                                                                                                                  | List the API versions that are available.                                                                                                             |
| apply         | kubectl apply -f FILENAME [flags]                                                                                                             | Apply a configuration change to a resource from a file or stdin.                                                                                      |
| attach        | kubectl attach POD -c CONTAINER [-i] [-t] [flags]                                                                                             | Attach to a running container either to view the output stream or interact with the container (stdin).                                                |
| auth          | kubectl auth [flags] [options]                                                                                                                | Inspect authorization.                                                                                                                                |
| autoscale     | kubectl autoscale (-f FILENAME   TYPE NAME   TYPE/NAME) [--min=MINPODS] --max=MAXPODS [--cpu-percent=CPU] [flags]                             | Automatically scale the set of pods that are managed by a replication controller.                                                                     |
| certificate   | kubectl certificate SUBCOMMAND [options]                                                                                                      | Modify certificate resources.                                                                                                                         |
| cluster-info  | kubectl cluster-info [flags]                                                                                                                  | Display endpoint information about the master and services in the cluster.                                                                            |
| completion    | kubectl completion SHELL [options]                                                                                                            | Output shell completion code for the specified shell (bash or zsh).                                                                                   |
| config        | kubectl config SUBCOMMAND [flags]                                                                                                             | Modifies kubeconfig files. See the individual subcommands for details.                                                                                |
| convert       | kubectl convert -f FILENAME [options]                                                                                                         | Convert config files between different API versions. Both YAML and JSON formats are accepted. Note - requires kubectl-convert plugin to be installed. |
| cordon        | kubectl cordon NODE [options]                                                                                                                 | Mark node as unschedulable.                                                                                                                           |

| replace      | kubectl replace -f FILENAME                                                                                                                             | Replace a resource from a file or stdin.                                                                  |
| rollout      | kubectl rollout SUBCOMMAND [options]                                                                                                                    | Manage the rollout of a resource. Valid resource types include: deployments, daemonsets and statefulsets. |
| run          | kubectl run NAME --image=image [--env="key=value"] [--port=port] [--dry-run=server client none] [--overrides=inline-json] [flags]                       | Run a specified image on the cluster.                                                                     |
| scale        | kubectl scale (-f FILENAME   TYPE NAME   TYPE/NAME) --replicas=COUNT [--resource-version=version] [--current-replicas=count] [flags]                    | Update the size of the specified replication controller.                                                  |
| set          | kubectl set SUBCOMMAND [options]                                                                                                                        | Configure application resources.                                                                          |
| taint        | kubectl taint NODE NAME<br>KEY_1=VAL_1:TAINT_EFFECT_1 ...<br>KEY_N=VAL_N:TAINT_EFFECT_N [options]                                                       | Update the taints on one or more nodes.                                                                   |
| top          | kubectl top (POD   NODE) [flags] [options]                                                                                                              | Display Resource (CPU/Memory/Storage) usage of pod or node.                                               |
| uncordon     | kubectl uncordon NODE [options]                                                                                                                         | Mark node as schedulable.                                                                                 |
| version      | kubectl version [--client] [flags]                                                                                                                      | Display the Kubernetes version running on the client and server.                                          |
| wait         | kubectl wait ([-f FILENAME]   resource.group/resource.name   resource.group [(-l label   --all)])<br>[--for=delete --for condition=available] [options] | Experimental: Wait for a specific condition on one or many resources.                                     |

To learn more about command operations, see the [kubectl](#) reference documentation.

## Resource types

The following table includes a list of all the supported resource types and their abbreviated aliases.

(This output can be retrieved from `kubectl api-resources`, and was accurate as of Kubernetes 1.25.0)

| NAME              | SHORTNAMES | APIVERSION | NAMESPACED | KIND            |
|-------------------|------------|------------|------------|-----------------|
| bindings          |            | v1         | true       | Binding         |
| componentstatuses | cs         | v1         | false      | ComponentStatus |
| configmaps        | cm         | v1         | true       | ConfigMap       |

| NAME                            | SHORTNAMES | APIVERSION                           | NAMESPACED | KIND                           |
|---------------------------------|------------|--------------------------------------|------------|--------------------------------|
| endpoints                       | ep         | v1                                   | true       | Endpoints                      |
| events                          | ev         | v1                                   | true       | Event                          |
| limitranges                     | limits     | v1                                   | true       | LimitRange                     |
| namespaces                      | ns         | v1                                   | false      | Namespace                      |
| nodes                           | no         | v1                                   | false      | Node                           |
| persistentvolumeclaims          | pvc        | v1                                   | true       | PersistentVolumeClaim          |
| persistentvolumes               | pv         | v1                                   | false      | PersistentVolume               |

## Output options

Use the following sections for information about how you can format or sort the output of certain commands. For details about which commands support the various output options, see the [kubectl](#) reference documentation.

### Formatting output

The default output format for all `kubectl` commands is the human readable plain-text format. To output details to your terminal window in a specific format, you can add either the `-o` or `--output` flags to a supported `kubectl` command.

### Syntax

```
kubectl [command] [TYPE] [NAME] -o <output_format>
```

Depending on the `kubectl` operation, the following output formats are supported:

| Output format                                        | Description                                                                                                    |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>-o custom-columns=&lt;spec&gt;</code>          | Print a table using a comma separated list of <a href="#">custom columns</a> .                                 |
| <code>-o custom-columns-file=&lt;filename&gt;</code> | Print a table using the <a href="#">custom columns</a> template in the <code>&lt;filename&gt;</code> file.     |
| <code>-o json</code>                                 | Output a JSON formatted API object.                                                                            |
| <code>-o jsonpath=&lt;template&gt;</code>            | Print the fields defined in a <a href="#">jsonpath</a> expression.                                             |
| <code>-o jsonpath-file=&lt;filename&gt;</code>       | Print the fields defined by the <a href="#">jsonpath</a> expression in the <code>&lt;filename&gt;</code> file. |
| <code>-o name</code>                                 | Print only the resource name and nothing else.                                                                 |
| <code>-o wide</code>                                 | Output in the plain-text format with any additional information. For pods, the node name is included.          |
| <code>-o yaml</code>                                 | Output a YAML formatted API object.                                                                            |

## Example

In this example, the following command outputs the details for a single pod as a YAML formatted object:

```
kubectl get pod web-pod-13je7 -o yaml
```

Remember: See the [kubectl](#) reference documentation for details about which output format is supported by each command.

## Custom columns

To define custom columns and output only the details that you want into a table, you can use the custom-columns option. You can choose to define the custom columns inline or use a template file: `-o custom-columns=<spec>` or `-o custom-columns-file=<filename>`.

### Examples

Inline:

```
kubectl get pods <pod-name> -o custom-columns=NAME:.metadata.name,RSRC:.metadata.resourceVersion
```

Template file:

```
kubectl get pods <pod-name> -o custom-columns-file=template.txt
```

where the template.txt file contains:

```
NAME RSRC
metadata.name metadata.resourceVersion
```

The result of running either command is similar to:

```
NAME RSRC
submit-queue 610995
```

## Server-side columns

kubectl supports receiving specific column information from the server about objects. This means that for any given resource, the server will return columns and rows relevant to that resource, for the client to print. This allows for consistent human-readable output across clients used against the same cluster, by having the server encapsulate the details of printing.

This feature is enabled by default. To disable it, add the `--server-print=false` flag to the kubectl get command.

### Examples

To print information about the status of a pod, use a command like the following:

```
kubectl get pods <pod-name> --server-print=false
```

The output is similar to:

```
NAME AGE
pod-name 1m
```

## Sorting list objects

To output objects to a sorted list in your terminal window, you can add the `--sort-by` flag to a supported `kubectl` command. Sort your objects by specifying any numeric or string field with the `--sort-by` flag. To specify a field, use a [jsonpath](#) expression.

### Syntax

```
kubectl [command] [TYPE] [NAME] --sort-by=<jsonpath_exp>
```

### Example

To print a list of pods sorted by name, you run:

```
kubectl get pods --sort-by=.metadata.name
```

## Examples: Common operations

Use the following set of examples to help you familiarize yourself with running the commonly used `kubectl` operations:

`kubectl apply` - Apply or Update a resource from a file or stdin.

```
Create a service using the definition in example-service.yaml.
kubectl apply -f example-service.yaml
```

```
Create a replication controller using the definition in example-controller.yaml.
kubectl apply -f example-controller.yaml
```

```
Create the objects that are defined in any .yaml, .yml, or .json file within the <directory>
directory.
kubectl apply -f <directory>
```

`kubectl get` - List one or more resources.

```
List all pods in plain-text output format.
kubectl get pods
```

```
List all pods in plain-text output format and include additional information (such as node
name).
kubectl get pods -o wide
```

```
List the replication controller with the specified name in plain-text output format. Tip: You
can shorten and replace the 'replicationcontroller' resource type with the alias 'rc'.
kubectl get replicationcontroller <rc-name>
```

```
List all replication controllers and services together in plain-text output format.
```

```
kubectl get rc,services
```

# List all daemon sets in plain-text output format.

```
kubectl get ds
```

# List all pods running on node server01

```
kubectl get pods --field-selector=spec.nodeName=server01
```

**kubectl describe** - Display detailed state of one or more resources, including the uninitialized ones by default.

# Display the details of the node with name <node-name>.

```
kubectl describe nodes <node-name>
```

# Display the details of the pod with name <pod-name>.

```
kubectl describe pods/<pod-name>
```

# Display the details of all the pods that are managed by the replication controller named <rc-name>.

# Remember: Any pods that are created by the replication controller get prefixed with the name of the replication controller.

```
kubectl describe pods <rc-name>
```

# Describe all pods

```
kubectl describe pods
```

### **Note:**

The **kubectl get** command is usually used for retrieving one or more resources of the same resource type. It features a rich set of flags that allows you to customize the output format using the **-o** or **--output** flag, for example. You can specify the **-w** or **--watch** flag to start watching updates to a particular object. The **kubectl describe** command is more focused on describing the many related aspects of a specified resource. It may invoke several API calls to the API server to build a view for the user. For example, the **kubectl describe node** command retrieves not only the information about the node, but also a summary of the pods running on it, the events generated for the node etc.

**kubectl delete** - Delete resources either from a file, stdin, or specifying label selectors, names, resource selectors, or resources.

# Delete a pod using the type and name specified in the pod.yaml file.

```
kubectl delete -f pod.yaml
```

# Delete all the pods and services that have the label '<label-key>=<label-value>'.

```
kubectl delete pods,services -l <label-key>=<label-value>
```

# Delete all pods, including uninitialized ones.

```
kubectl delete pods --all
```

**kubectl exec** - Execute a command against a container in a pod.

# Get output from running 'date' from pod <pod-name>. By default, output is from the first container.

```
kubectl exec <pod-name> -- date
```

```
Get output from running 'date' in container <container-name> of pod <pod-name>.
kubectl exec <pod-name> -c <container-name> -- date
```

```
Get an interactive TTY and run /bin/bash from pod <pod-name>. By default, output is from
the first container.
kubectl exec -ti <pod-name> -- /bin/bash
```

`kubectl logs` - Print the logs for a container in a pod.

```
Return a snapshot of the logs from pod <pod-name>.
kubectl logs <pod-name>
```

```
Start streaming the logs from pod <pod-name>. This is similar to the 'tail -f' Linux command.
kubectl logs -f <pod-name>
```

`kubectl diff` - View a diff of the proposed updates to a cluster.

```
Diff resources included in "pod.json".
kubectl diff -f pod.json
```

```
Diff file read from stdin.
cat service.yaml | kubectl diff -f -
```

## Examples: Creating and using plugins

Use the following set of examples to help you familiarize yourself with writing and using `kubectl` plugins:

```
create a simple plugin in any language and name the resulting executable file
so that it begins with the prefix "kubectl-"
cat ./kubectl-hello
```

```
#!/bin/sh
```

```
this plugin prints the words "hello world"
echo "hello world"
```

With a plugin written, let's make it executable:

```
chmod a+x ./kubectl-hello
```

```
and move it to a location in our PATH
sudo mv ./kubectl-hello /usr/local/bin
sudo chown root:root /usr/local/bin
```

```
You have now created and "installed" a kubectl plugin.
You can begin using this plugin by invoking it from kubectl as if it were a regular command
kubectl hello
```

```
hello world
```

```
You can "uninstall" a plugin, by removing it from the folder in your
$PATH where you placed it
sudo rm /usr/local/bin/kubectl-hello
```

In order to view all of the plugins that are available to kubectl, use the kubectl plugin list subcommand:

```
kubectl plugin list
```

The output is similar to:

The following kubectl-compatible plugins are available:

```
/usr/local/bin/kubectl-hello
/usr/local/bin/kubectl-foo
/usr/local/bin/kubectl-bar
```

kubectl plugin list also warns you about plugins that are not executable, or that are shadowed by other plugins; for example:

```
sudo chmod -x /usr/local/bin/kubectl-foo # remove execute permission
kubectl plugin list
```

The following kubectl-compatible plugins are available:

```
/usr/local/bin/kubectl-hello
/usr/local/bin/kubectl-foo
- warning: /usr/local/bin/kubectl-foo identified as a plugin, but it is not executable
/usr/local/bin/kubectl-bar
```

```
error: one plugin warning was found
```

You can think of plugins as a means to build more complex functionality on top of the existing kubectl commands:

```
cat ./kubectl-whoami
```

The next few examples assume that you already made kubectl-whoami have the following contents:

```
#!/bin/bash

this plugin makes use of the `kubectl config` command in order to output
information about the current user, based on the currently selected context
kubectl config view --template='{{ range .contexts }}{{ if eq .name "$(kubectl config current-
context)" }}Current user: {{ printf "%s\n" .context.user }}{{ end }}{{ end }}'
```

Running the above command gives you an output containing the user for the current context in your KUBECONFIG file:

```
make the file executable
sudo chmod +x ./kubectl-whoami
```

```
and move it into your PATH
```

```
sudo mv ./kubectl-whoami /usr/local/bin
```

```
kubectl whoami
```

```
Current user: plugins-user
```

## What's next

- Read the [kubectl reference documentation](#):
  - the [kubectl command reference](#)
  - the [command line arguments](#) reference
- Learn about [kubectl usage conventions](#)
- Read about [JSONPath support](#) in kubectl
- Read about how to [extend kubectl with plugins](#)
  - To find out more about plugins, take a look at the [example CLI plugin](#).

# Introduction to kubectl

kubectl is the Kubernetes cli version of a swiss army knife, and can do many things.

While this Book is focused on using kubectl to declaratively manage applications in Kubernetes, it also covers other kubectl functions.

## Command Families

Most kubectl commands typically fall into one of a few categories:

| Type                            | Used For                                | Description                                                                        |
|---------------------------------|-----------------------------------------|------------------------------------------------------------------------------------|
| Declarative Resource Management | Deployment and operations (e.g. GitOps) | Declaratively manage Kubernetes workloads using resource configuration             |
| Imperative Resource Management  | Development Only                        | Run commands to manage Kubernetes workloads using Command Line arguments and flags |
| Printing Workload State         | Debugging                               | Print information about workloads                                                  |
| Interacting with Containers     | Debugging                               | Exec, attach, cp, logs                                                             |
| Cluster Management              | Cluster operations                      | Drain and cordon Nodes                                                             |

## Declarative Application Management

The preferred approach for managing resources is through declarative files called resource configuration used with the kubectl *Apply* command. This command reads a local (or remote) file structure and modifies cluster state to reflect the declared intent.

### Apply

Apply is the preferred mechanism for managing resources in a Kubernetes cluster.

## Printing State about Workloads

Users will need to view workload state.

- Printing summarize state and information about resources
- Printing complete state and information about resources
- Printing specific fields from resources
- Query resources matching labels

## Debugging Workloads

kubectl supports debugging by providing commands for:

- Printing Container logs
- Printing cluster events
- Exec or attaching to a Container
- Copying files from Containers in the cluster to a user's filesystem

## Cluster Management

On occasion, users may need to perform operations to the Nodes of cluster. kubectl supports commands to drain workloads from a Node so that it can be decommissioned or debugged.

## Porcelain

Users may find using resource configuration overly verbose for *development* and prefer to work with the cluster *imperatively* with a shell-like workflow. kubectl offers porcelain commands for generating and modifying resources.

- Generating + creating resources such as Deployments, StatefulSets, Services, ConfigMaps, etc.
- Setting fields on resources
- Editing (live) resources in a text editor

### Porcelain for Dev Only

Porcelain commands are time saving for experimenting with workloads in a dev cluster, but shouldn't be used for production.

## kubectl Quick Reference

This page contains a list of commonly used kubectl commands and flags.

### Note:

These instructions are for Kubernetes v1.30. To check the version, use the `kubectl version` command.

# Kubectl autocomplete

## BASH

```
source <(kubectl completion bash) # set up autocomplete in bash into the current shell, bash-
completion package should be installed first.
echo "source <(kubectl completion bash)" >> ~/.bashrc
add autocomplete permanently to your bash shell.
```

You can also use a shorthand alias for kubectl that also works with completion:

```
alias k=kubectl
complete -o default -F __start_kubectl k
```

## ZSH

```
source <(kubectl completion zsh) # set up autocomplete in zsh into the current shell
echo '[[$commands[kubectl]]] && source <(kubectl completion zsh)' >> ~/.zshrc # add
autocomplete permanently to your zsh shell
```

## FISH

### Note:

Requires kubectl version 1.23 or above.

```
echo 'kubectl completion fish | source' > ~/.config/fish/completions/kubectl.fish && source
~/.config/fish/completions/kubectl.fish
```

### A note on --all-namespaces

Appending --all-namespaces happens frequently enough that you should be aware of the shorthand for --all-namespaces:

```
kubectl -A
```

## Kubectl context and configuration

Set which Kubernetes cluster kubectl communicates with and modifies configuration information. See [Authenticating Across Clusters with kubeconfig](#) documentation for detailed config file information.

```
kubectl config view # Show Merged kubeconfig settings.
```

```
use multiple kubeconfig files at the same time and view merged config
KUBECONFIG=~/.kube/config:~/.kube/kubconfig2
```

```
kubectl config view
```

```
Show merged kubeconfig settings and raw certificate data and exposed secrets
kubectl config view --raw
```

```
get the password for the e2e user
kubectl config view -o jsonpath='{.users[?(@.name == "e2e")].user.password}'

get the certificate for the e2e user
kubectl config view --raw -o jsonpath='{.users[?(@.name == "e2e")].user.client-certificate-data}' |
base64 -d

kubectl config view -o jsonpath='{.users[].name}' # display the first user
kubectl config view -o jsonpath='{.users[*].name}' # get a list of users
kubectl config get-contexts # display list of contexts
kubectl config get-contexts -o name # get all context names
kubectl config current-context # display the current-context
kubectl config use-context my-cluster-name # set the default context to my-cluster-name

kubectl config set-cluster my-cluster-name # set a cluster entry in the kubeconfig

configure the URL to a proxy server to use for requests made by this client in the kubeconfig
kubectl config set-cluster my-cluster-name --proxy-url=my-proxy-url

add a new user to your kubeconfig that supports basic auth
kubectl config set-credentials kubeuser/foo.kubernetes.com --username=kubeuser --
password=kubepassword

permanently save the namespace for all subsequent kubectl commands in that context.
kubectl config set-context --current --namespace=ggckad-s2

set a context utilizing a specific username and namespace.
kubectl config set-context gce --user=cluster-admin --namespace=foo \
&& kubectl config use-context gce

kubectl config unset users.foo # delete user foo

short alias to set/show context/namespace (only works for bash and bash-compatible shells,
current context to be set before using kn to set namespace)
alias kx='f() { ["$1"] && kubectl config use-context $1 || kubectl config current-context ; } ; f'
alias kn='f() { ["$1"] && kubectl config set-context --current --namespace $1 || kubectl config
view --minify | grep namespace | cut -d" " -f6 ; } ; f'
```

## Kubectl apply

apply manages applications through files defining Kubernetes resources. It creates and updates resources in a cluster through running kubectl apply. This is the recommended way of managing Kubernetes applications on production. See [Kubectl Book](#).

## Creating objects

Kubernetes manifests can be defined in YAML or JSON. The file extension .yaml, .yml, and .json can be used.

```
kubectl apply -f ./my-manifest.yaml # create resource(s)
kubectl apply -f ./my1.yaml -f ./my2.yaml # create from multiple files
```

```

kubectl apply -f ./dir # create resource(s) in all manifest files in dir
kubectl apply -f https://example.com/manifest.yaml # create resource(s) from url (Note: this is
an example domain and does not contain a valid manifest)
kubectl create deployment nginx --image=nginx # start a single instance of nginx

create a Job which prints "Hello World"
kubectl create job hello --image=busybox:1.28 -- echo "Hello World"

create a CronJob that prints "Hello World" every minute
kubectl create cronjob hello --image=busybox:1.28 --schedule="*/1 * * * *" -- echo "Hello
World"

kubectl explain pods # get the documentation for pod manifests

Create multiple YAML objects from stdin
kubectl apply -f - <<EOF
apiVersion: v1
kind: Pod
metadata:
 name: busybox-sleep
spec:
 containers:
 - name: busybox
 image: busybox:1.28
 args:
 - sleep
 - "1000000"

apiVersion: v1
kind: Pod
metadata:
 name: busybox-sleep-less
spec:
 containers:
 - name: busybox
 image: busybox:1.28
 args:
 - sleep
 - "1000"
EOF

Create a secret with several keys
kubectl apply -f - <<EOF
apiVersion: v1
kind: Secret
metadata:
 name: mysecret
type: Opaque
data:
 password: $(echo -n "s33msi4" | base64 -w0)
 username: $(echo -n "jane" | base64 -w0)
EOF

```

## Viewing and finding resources

```
Get commands with basic output
kubectl get services # List all services in the namespace
kubectl get pods --all-namespaces # List all pods in all namespaces
kubectl get pods -o wide # List all pods in the current namespace, with more
 # details
kubectl get deployment my-dep # List a particular deployment
kubectl get pods # List all pods in the namespace
kubectl get pod my-pod -o yaml # Get a pod's YAML

Describe commands with verbose output
kubectl describe nodes my-node
kubectl describe pods my-pod

List Services Sorted by Name
kubectl get services --sort-by=.metadata.name

List pods Sorted by Restart Count
kubectl get pods --sort-by='.status.containerStatuses[0].restartCount'

List PersistentVolumes sorted by capacity
kubectl get pv --sort-by=.spec.capacity.storage

Get the version label of all pods with label app=cassandra
kubectl get pods --selector=app=cassandra -o \
 jsonpath='{.items[*].metadata.labels.version}'

Retrieve the value of a key with dots, e.g. 'ca.crt'
kubectl get configmap myconfig \
 -o jsonpath='{.data.ca\.crt}'

Retrieve a base64 encoded value with dashes instead of underscores.
kubectl get secret my-secret --template='{{index .data "key-name-with-dashes"}}'

Get all worker nodes (use a selector to exclude results that have a label
named 'node-role.kubernetes.io/control-plane')
kubectl get node --selector='!node-role.kubernetes.io/control-plane'

Get all running pods in the namespace
kubectl get pods --field-selector=status.phase=Running

Get ExternalIPs of all nodes
kubectl get nodes -o jsonpath='{.items[*].status.addresses[?(@.type=="ExternalIP")].address}'

List Names of Pods that belong to Particular RC
"jq" command useful for transformations that are too complex for jsonpath, it can be found at
https://jqlang.github.io/jq/
sel=${$(kubectl get rc my-rc --output=json | jq -j '.spec.selector | to_entries | .[] | "\(.key)=\'
(.value),\'")%?'}
echo $(kubectl get pods --selector=$sel --output=jsonpath='{.items..metadata.name}')
```

```

Show labels for all pods (or any other Kubernetes object that supports labelling)
kubectl get pods --show-labels

Check which nodes are ready
JSONPATH='{range .items[*]}{@.metadata.name}:{range @.status.conditions[*]}{@.type}
={@.status};{end}{end}' \
&& kubectl get nodes -o jsonpath="$JSONPATH" | grep "Ready=True"

Check which nodes are ready with custom-columns
kubectl get node -o custom-columns='NODE_NAME:.metadata.name,STATUS:.status.conditions
[?(@.type=="Ready")].status'

Output decoded secrets without external tools
kubectl get secret my-secret -o go-template='{{range $k,$v := .data}}{{"### "}}{{$k}}{{"\n"}}{{ $v|
base64decode}}{{"\n\n"}}{{end}}'

List all Secrets currently in use by a pod
kubectl get pods -o json | jq '.items[].spec.containers[].env[]?.valueFrom.secretKeyRef.name' |
grep -v null | sort | uniq

List all containerIDs of initContainer of all pods
Helpful when cleaning up stopped containers, while avoiding removal of initContainers.
kubectl get pods --all-namespaces -o jsonpath='{range .items[*].status.initContainerStatuses[*]}
{.containerID}{"\n"}{end}' | cut -d/ -f3

List Events sorted by timestamp
kubectl get events --sort-by=.metadata.creationTimestamp

List all warning events
kubectl events --types=Warning

Compares the current state of the cluster against the state that the cluster would be in if the
manifest was applied.
kubectl diff -f ./my-manifest.yaml

Produce a period-delimited tree of all keys returned for nodes
Helpful when locating a key within a complex nested JSON structure
kubectl get nodes -o json | jq -c 'paths|join(".")'

Produce a period-delimited tree of all keys returned for pods, etc
kubectl get pods -o json | jq -c 'paths|join(".")'

Produce ENV for all pods, assuming you have a default container for the pods, default
namespace and the `env` command is supported.
Helpful when running any supported command across all pods, not just `env`
for pod in $(kubectl get po --output=jsonpath={.items..metadata.name}); do echo $pod &&
kubectl exec -it $pod -- env; done

Get a deployment's status subresource
kubectl get deployment nginx-deployment --subresource=status

```

## Updating resources

```
kubectl set image deployment/frontend www=image:v2 # Rolling update "www"
containers of "frontend" deployment, updating the image
kubectl rollout history deployment/frontend # Check the history of deployments
including the revision
kubectl rollout undo deployment/frontend # Rollback to the previous deployment
kubectl rollout undo deployment/frontend --to-revision=2 # Rollback to a specific revision
kubectl rollout status -w deployment/frontend # Watch rolling update status of
"frontend" deployment until completion
kubectl rollout restart deployment/frontend # Rolling restart of the "frontend"
deployment

cat pod.json | kubectl replace -f - # Replace a pod based on the JSON passed
into stdin

Force replace, delete and then re-create the resource. Will cause a service outage.
kubectl replace --force -f ./pod.json

Create a service for a replicated nginx, which serves on port 80 and connects to the containers
on port 8000
kubectl expose rc nginx --port=80 --target-port=8000

Update a single-container pod's image version (tag) to v4
kubectl get pod mypod -o yaml | sed 's/\(image: myimage\):.*$/1:v4/' | kubectl replace -f -

kubectl label pods my-pod new-label=awesome # Add a Label
kubectl label pods my-pod new-label- # Remove a label
kubectl label pods my-pod new-label=new-value --overwrite # Overwrite an existing value
kubectl annotate pods my-pod icon-url=http://goo.gl/XXBTWq # Add an annotation
kubectl annotate pods my-pod icon-url- # Remove annotation
kubectl autoscale deployment foo --min=2 --max=10 # Auto scale a deployment "foo"
```

## Patching resources

```
Partially update a node
kubectl patch node k8s-node-1 -p '{"spec":{"unschedulable":true}}'

Update a container's image; spec.containers[*].name is required because it's a merge key
kubectl patch pod valid-pod -p '{"spec":{"containers":[{"name":"kubernetes-serve-
hostname","image":"new image"}]}}'

Update a container's image using a json patch with positional arrays
kubectl patch pod valid-pod --type=json -p='[{"op": "replace", "path": "/spec/containers/0/
image", "value":"new image"}]'

Disable a deployment livenessProbe using a json patch with positional arrays
kubectl patch deployment valid-deployment --type json -p='[{"op": "remove", "path": "/spec/
template/spec/containers/0/livenessProbe"}]'

Add a new element to a positional array
```

```
kubectl patch sa default --type='json' -p='[{"op": "add", "path": "/secrets/1", "value": {"name": "whatever" } }]'
```

# Update a deployment's replica count by patching its scale subresource

```
kubectl patch deployment nginx-deployment --subresource='scale' --type='merge' -p '{"spec": {"replicas":2}}'
```

## Editing resources

Edit any API resource in your preferred editor.

```
kubectl edit svc/docker-registry # Edit the service named docker-registry
```

```
KUBE_EDITOR="nano" kubectl edit svc/docker-registry # Use an alternative editor
```

## Scaling resources

```
kubectl scale --replicas=3 rs/foo # Scale a replicaset named 'foo' to 3
```

```
kubectl scale --replicas=3 -f foo.yaml # Scale a resource specified in "foo.yaml" to 3
```

```
kubectl scale --current-replicas=2 --replicas=3 deployment/mysql # If the deployment named mysql's current size is 2, scale mysql to 3
```

```
kubectl scale --replicas=5 rc/foo rc/bar rc/baz # Scale multiple replication controllers
```

## Deleting resources

```
kubectl delete -f ./pod.json # Delete a pod using the type and name specified in pod.json
```

```
kubectl delete pod unwanted --now # Delete a pod with no grace period
```

```
kubectl delete pod,service baz foo # Delete pods and services with same names "baz" and "foo"
```

```
kubectl delete pods,services -l name=myLabel # Delete pods and services with label name=myLabel
```

```
kubectl -n my-ns delete pod,svc --all # Delete all pods and services in namespace my-ns,
```

# Delete all pods matching the awk pattern1 or pattern2

```
kubectl get pods -n mynamespace --no-headers=true | awk '/pattern1|pattern2/{print $1}' | xargs kubectl delete -n mynamespace pod
```

## Interacting with running Pods

```
kubectl logs my-pod # dump pod logs (stdout)
```

```
kubectl logs -l name=myLabel # dump pod logs, with label name=myLabel (stdout)
```

```
kubectl logs my-pod --previous # dump pod logs (stdout) for a previous instantiation of a container
```

```
kubectl logs my-pod -c my-container # dump pod container logs (stdout, multi-container case)
```

```
kubectl logs -l name=myLabel -c my-container # dump pod container logs, with label name=myLabel (stdout)
```

```
kubectl logs my-pod -c my-container --previous # dump pod container logs (stdout, multi-
```

```

container case) for a previous instantiation of a container
kubectl logs -f my-pod # stream pod logs (stdout)
kubectl logs -f my-pod -c my-container # stream pod container logs (stdout, multi-
container case)
kubectl logs -f -l name=myLabel --all-containers # stream all pods logs with label
name=myLabel (stdout)
kubectl run -i --tty busybox --image=busybox:1.28 -- sh # Run pod as interactive shell
kubectl run nginx --image=nginx -n mynamespace # Start a single instance of nginx pod in
the namespace of mynamespace
kubectl run nginx --image=nginx --dry-run=client -o yaml > pod.yaml
Generate spec for running pod nginx and write it into a file
called pod.yaml
kubectl attach my-pod -i # Attach to Running Container
kubectl port-forward my-pod 5000:6000
Listen on port 5000 on the local machine and forward to port 6000 on my-pod
kubectl exec my-pod -- ls / # Run command in existing pod (1 container case)
kubectl exec --stdin --tty my-pod -- /bin/sh # Interactive shell access to a running pod (1
container case)
kubectl exec my-pod -c my-container -- ls / # Run command in existing pod (multi-
container case)
kubectl debug my-pod -it --image=busybox:1.28 # Create an interactive debugging session
within existing pod and immediately attach to it
kubectl debug node/my-node -it --image=busybox:1.28 # Create an interactive debugging
session on a node and immediately attach to it
kubectl top pod # Show metrics for all pods in the default namespace
kubectl top pod POD_NAME --containers # Show metrics for a given pod and its
containers
kubectl top pod POD_NAME --sort-by=cpu # Show metrics for a given pod and sort it
by 'cpu' or 'memory'

```

## Copying files and directories to and from containers

```

kubectl cp /tmp/foo_dir my-pod:/tmp/bar_dir # Copy /tmp/foo_dir local directory to /
tmp/bar_dir in a remote pod in the current namespace
kubectl cp /tmp/foo my-pod:/tmp/bar -c my-container # Copy /tmp/foo local file to /tmp/bar
in a remote pod in a specific container
kubectl cp /tmp/foo my-namespace/my-pod:/tmp/bar # Copy /tmp/foo local file to /tmp/bar
in a remote pod in namespace my-namespace
kubectl cp my-namespace/my-pod:/tmp/foo /tmp/bar # Copy /tmp/foo from a remote pod
to /tmp/bar locally

```

### Note:

kubectl cp requires that the 'tar' binary is present in your container image. If 'tar' is not present, kubectl cp will fail. For advanced use cases, such as symlinks, wildcard expansion or file mode preservation consider using kubectl exec.

```

tar cf - /tmp/foo | kubectl exec -i -n my-namespace my-pod -- tar xf - -C /tmp/bar #
Copy /tmp/foo local file to /tmp/bar in a remote pod in namespace my-namespace
kubectl exec -n my-namespace my-pod -- tar cf - /tmp/foo | tar xf - -C /tmp/bar # Copy /tmp/
foo from a remote pod to /tmp/bar locally

```

## Interacting with Deployments and Services

```
kubectl logs deploy/my-deployment # dump Pod logs for a Deployment (single-
container case)
kubectl logs deploy/my-deployment -c my-container # dump Pod logs for a Deployment
(multi-container case)

kubectl port-forward svc/my-service 5000 # listen on local port 5000 and forward to
port 5000 on Service backend
kubectl port-forward svc/my-service 5000:my-service-port # listen on local port 5000 and
forward to Service target port with name <my-service-port>

kubectl port-forward deploy/my-deployment 5000:6000 # listen on local port 5000 and
forward to port 6000 on a Pod created by <my-deployment>
kubectl exec deploy/my-deployment -- ls # run command in first Pod and first
container in Deployment (single- or multi-container cases)
```

## Interacting with Nodes and cluster

```
kubectl cordon my-node # Mark my-node as unschedulable
kubectl drain my-node # Drain my-node in preparation for
maintenance
kubectl uncordon my-node # Mark my-node as schedulable
kubectl top node # Show metrics for all nodes
kubectl top node my-node # Show metrics for a given node
kubectl cluster-info # Display addresses of the master and
services
kubectl cluster-info dump # Dump current cluster state to stdout
kubectl cluster-info dump --output-directory=/path/to/cluster-state # Dump current cluster
state to /path/to/cluster-state

View existing taints on which exist on current nodes.
kubectl get nodes -o='custom-
columns=NodeName:.metadata.name,TaintKey:.spec.taints[*].key,TaintValue:.spec.taints[*].valu
e,TaintEffect:.spec.taints[*].effect'

If a taint with that key and effect already exists, its value is replaced as specified.
kubectl taint nodes foo dedicated=special-user:NoSchedule
```

## Resource types

List all supported resource types along with their shortnames, [API group](#), whether they are [namespaced](#), and [kind](#):

```
kubectl api-resources
```

Other operations for exploring API resources:

```
kubectl api-resources --namespaced=true # All namespaced resources
kubectl api-resources --namespaced=false # All non-namespaced resources
kubectl api-resources -o name # All resources with simple output (only the resource
name)
```

```
kubectl api-resources -o wide # All resources with expanded (aka "wide") output
kubectl api-resources --verbs=list,get
All resources that support the "list" and "get" request verbs
kubectl api-resources --api-group=extensions # All resources in the "extensions" API group
```

## Formatting output

To output details to your terminal window in a specific format, add the `-o` (or `--output`) flag to a supported `kubectl` command.

| Output format                                        | Description                                                                                                   |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>-o=custom-columns=&lt;spec&gt;</code>          | Print a table using a comma separated list of custom columns                                                  |
| <code>-o=custom-columns-file=&lt;filename&gt;</code> | Print a table using the custom columns template in the <code>&lt;filename&gt;</code> file                     |
| <code>-o=go-template=&lt;template&gt;</code>         | Print the fields defined in a <a href="#">golang template</a>                                                 |
| <code>-o=go-template-file=&lt;filename&gt;</code>    | Print the fields defined by the <a href="#">golang template</a> in the <code>&lt;filename&gt;</code> file     |
| <code>-o=json</code>                                 | Output a JSON formatted API object                                                                            |
| <code>-o=jsonpath=&lt;template&gt;</code>            | Print the fields defined in a <a href="#">jsonpath</a> expression                                             |
| <code>-o=jsonpath-file=&lt;filename&gt;</code>       | Print the fields defined by the <a href="#">jsonpath</a> expression in the <code>&lt;filename&gt;</code> file |
| <code>-o=name</code>                                 | Print only the resource name and nothing else                                                                 |
| <code>-o=wide</code>                                 | Output in the plain-text format with any additional information, and for pods, the node name is included      |
| <code>-o=yaml</code>                                 | Output a YAML formatted API object                                                                            |

Examples using `-o=custom-columns`:

```
All images running in a cluster
kubectl get pods -A -o=custom-columns='DATA:spec.containers[*].image'

All images running in namespace: default, grouped by Pod
kubectl get pods --namespace default --output=custom-columns="NAME:.metadata.name,IMAGE:.spec.containers[*].image"

All images excluding "registry.k8s.io/coredns:1.6.2"
kubectl get pods -A -o=custom-columns='DATA:spec.containers[?(@.image!="registry.k8s.io/coredns:1.6.2")].image'

All fields under metadata regardless of name
kubectl get pods -A -o=custom-columns='DATA:metadata.*'
```

More examples in the [kubectl reference documentation](#).

## Kubectl output verbosity and debugging

Kubectl verbosity is controlled with the `-v` or `--v` flags followed by an integer representing the log level. General Kubernetes logging conventions and the associated log levels are described [here](#).

| Verbosity | Description                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --v=0     | Generally useful for this to <i>always</i> be visible to a cluster operator.                                                                                                                      |
| --v=1     | A reasonable default log level if you don't want verbosity.                                                                                                                                       |
| --v=2     | Useful steady state information about the service and important log messages that may correlate to significant changes in the system. This is the recommended default log level for most systems. |
| --v=3     | Extended information about changes.                                                                                                                                                               |
| --v=4     | Debug level verbosity.                                                                                                                                                                            |
| --v=5     | Trace level verbosity.                                                                                                                                                                            |
| --v=6     | Display requested resources.                                                                                                                                                                      |
| --v=7     | Display HTTP request headers.                                                                                                                                                                     |
| --v=8     | Display HTTP request contents.                                                                                                                                                                    |
| --v=9     | Display HTTP request contents without truncation of contents.                                                                                                                                     |

## What's next

- Read the [kubectl overview](#) and learn about [JsonPath](#).
- See [kubectl](#) options.
- Also read [kubectl Usage Conventions](#) to understand how to use kubectl in reusable scripts.
- See more community [kubectl cheatsheets](#).

# kubectl

## Synopsis

kubectl controls the Kubernetes cluster manager.

Find more information at: <https://kubernetes.io/docs/reference/kubectl/>

kubectl [flags]

## Options

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| -h, --help                                                                                                                                                      |
| help for kubectl                                                                                                                                                |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |

- [kubectl get](#) - Display one or many resources
- [kubectl kustomize](#) - Build a kustomization target from a directory or URL
- [kubectl label](#) - Update the labels on a resource
- [kubectl logs](#) - Print the logs for a container in a pod
- [kubectl options](#) - Print the list of flags inherited by all commands
- [kubectl patch](#) - Update fields of a resource
- [kubectl plugin](#) - Provides utilities for interacting with plugins
- [kubectl port-forward](#) - Forward one or more local ports to a pod
- [kubectl proxy](#) - Run a proxy to the Kubernetes API server
- [kubectl replace](#) - Replace a resource by file name or stdin
- [kubectl rollout](#) - Manage the rollout of a resource
- [kubectl run](#) - Run a particular image on the cluster
- [kubectl scale](#) - Set a new size for a deployment, replica set, or replication controller
- [kubectl set](#) - Set specific features on objects
- [kubectl taint](#) - Update the taints on one or more nodes
- [kubectl top](#) - Display resource (CPU/memory) usage
- [kubectl unordon](#) - Mark node as schedulable
- [kubectl version](#) - Print the client and server version information
- [kubectl wait](#) - Experimental: Wait for a specific condition on one or many resources

# kubectl annotate

## Synopsis

Update the annotations on one or more resources.

All Kubernetes objects support the ability to store additional data with the object as annotations. Annotations are key/value pairs that can be larger than labels and include arbitrary string values such as structured JSON. Tools and system extensions may use annotations to store their own data.

Attempting to set an annotation that already exists will fail unless `--overwrite` is set. If `--resource-version` is specified and does not match the current resource version on the server the command will fail.

Use "kubectl api-resources" for a complete list of supported resources.

kubectl annotate [--overwrite] (-f FILENAME | TYPE NAME) KEY\_1=VAL\_1 ... KEY\_N=VAL\_N  
[--resource-version=version]

## Examples

```
Update pod 'foo' with the annotation 'description' and the value 'my frontend'
If the same annotation is set multiple times, only the last value will be applied
kubectl annotate pods foo description='my frontend'

Update a pod identified by type and name in "pod.json"
kubectl annotate -f pod.json description='my frontend'

Update pod 'foo' with the annotation 'description' and the value 'my frontend running nginx',
overwriting any existing value
kubectl annotate --overwrite pods foo description='my frontend running nginx'

Update all pods in the namespace
kubectl annotate pods --all description='my frontend running nginx'

Update pod 'foo' only if the resource is unchanged from version 1
kubectl annotate pods foo description='my frontend running nginx' --resource-version=1

Update pod 'foo' by removing an annotation named 'description' if it exists
Does not require the --overwrite flag
kubectl annotate pods foo description-
```

|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --all                                                                                                                                                                                                    |
| Select all resources, in the namespace of the specified resource types.                                                                                                                                  |
| -A, --all-namespaces                                                                                                                                                                                     |
| If true, check the specified action in all namespaces.                                                                                                                                                   |
| --allow-missing-template-keys    Default: true                                                                                                                                                           |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                          |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-annotate"                                                                                                                                                    |
| Name of the manager used to track field ownership.                                                                                                                                                       |

|                           |                                                                                                                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --field-selector string   |                                                                                                                                                                                         |
|                           | Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type. |
| -f, --filename strings    |                                                                                                                                                                                         |
|                           | Filename, directory, or URL to files identifying the resource to update the annotation                                                                                                  |
| -h, --help                |                                                                                                                                                                                         |
|                           | help for annotate                                                                                                                                                                       |
| -k, --kustomize string    |                                                                                                                                                                                         |
|                           | Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                    |
| --list                    |                                                                                                                                                                                         |
|                           | If true, display the annotations for a given resource.                                                                                                                                  |
| --local                   |                                                                                                                                                                                         |
|                           | If true, annotation will NOT contact api-server but run locally.                                                                                                                        |
| -o, --output string       |                                                                                                                                                                                         |
|                           | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                            |
| --overwrite               |                                                                                                                                                                                         |
|                           | If true, allow annotations to be overwritten, otherwise reject annotation updates that overwrite existing annotations.                                                                  |
| -R, --recursive           |                                                                                                                                                                                         |
|                           | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                         |
| --resource-version string |                                                                                                                                                                                         |
|                           | If non-empty, the annotation update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.                             |
| -l, --selector string     |                                                                                                                                                                                         |
|                           | Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.              |
| --show-managed-fields     |                                                                                                                                                                                         |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --as string                                                                                                                                                                                                                                               |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                              |
| --as-group strings                                                                                                                                                                                                                                        |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                                                                                                             |
| --as-uid string                                                                                                                                                                                                                                           |
| UID to impersonate for the operation.                                                                                                                                                                                                                     |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                                                                                                                        |
| Default cache directory                                                                                                                                                                                                                                   |

| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-s, --server string</code>                                                                                                  |
| The address and port of the Kubernetes API server                                                                                 |
| <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                              |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| <code>--storage-driver-db string</code> Default: "cadvisor"                                                                       |
| database name                                                                                                                     |
| <code>--storage-driver-host string</code> Default: "localhost:8086"                                                               |
| database host:port                                                                                                                |
| <code>--storage-driver-password string</code> Default: "root"                                                                     |
| database password                                                                                                                 |
| <code>--storage-driver-secure</code>                                                                                              |
| use secure connection with database                                                                                               |
| <code>--storage-driver-table string</code> Default: "stats"                                                                       |
| table name                                                                                                                        |
| <code>--storage-driver-user string</code> Default: "root"                                                                         |
| database username                                                                                                                 |
| <code>--tls-server-name string</code>                                                                                             |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| <code>--token string</code>                                                                                                       |
| Bearer token for authentication to the API server                                                                                 |
| <code>--user string</code>                                                                                                        |
| The name of the kubeconfig user to use                                                                                            |
| <code>--username string</code>                                                                                                    |
| Username for basic authentication to the API server                                                                               |
| <code>--version version[=true]</code>                                                                                             |

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>--version, --version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
|----------------------------------------------------------------------------------------------------------------------------------------|

|                                   |
|-----------------------------------|
| <code>--warnings-as-errors</code> |
|-----------------------------------|

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

# kubectl api-resources

## Synopsis

Print the supported API resources on the server.

```
kubectl api-resources [flags]
```

## Examples

```
Print the supported API resources
kubectl api-resources
```

```
Print the supported API resources with more information
kubectl api-resources -o wide
```

```
Print the supported API resources sorted by a column
kubectl api-resources --sort-by=name
```

```
Print the supported namespaced resources
kubectl api-resources --namespaced=true
```

```
Print the supported non-namespaced resources
kubectl api-resources --namespaced=false
```

```
Print the supported API resources with a specific APIGroup
kubectl api-resources --api-group=rbac.authorization.k8s.io
```

## Options

|                                 |
|---------------------------------|
| <code>--api-group string</code> |
|---------------------------------|

|                                                |
|------------------------------------------------|
| Limit to resources in the specified API group. |
|------------------------------------------------|

|                       |
|-----------------------|
| <code>--cached</code> |
|-----------------------|

|                                         |                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------|
|                                         | Use the cached list of resources if available.                                                            |
| <code>--categories strings</code>       |                                                                                                           |
|                                         | Limit to resources that belong to the specified categories.                                               |
| <code>-h, --help</code>                 |                                                                                                           |
|                                         | help for api-resources                                                                                    |
| <code>--namespaced</code> Default: true |                                                                                                           |
|                                         | If false, non-namespaced resources will be returned, otherwise returning namespaced resources by default. |
| <code>--no-headers</code>               |                                                                                                           |
|                                         | When using the default or custom-column output format, don't print headers (default print headers).       |
| <code>-o, --output string</code>        |                                                                                                           |
|                                         | Output format. One of: (wide, name).                                                                      |
| <code>--sort-by string</code>           |                                                                                                           |
|                                         | If non-empty, sort list of resources using specified field. The field can be either 'name' or 'kind'.     |
| <code>--verbs strings</code>            |                                                                                                           |
|                                         | Limit to resources that support the specified verbs.                                                      |

|                                                               |                                                                                                              |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>--as string</code>                                      |                                                                                                              |
|                                                               | Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| <code>--as-group strings</code>                               |                                                                                                              |
|                                                               | Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| <code>--as-uid string</code>                                  |                                                                                                              |
|                                                               | UID to impersonate for the operation.                                                                        |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache" |                                                                                                              |
|                                                               | Default cache directory                                                                                      |
| <code>--certificate-authority string</code>                   |                                                                                                              |

|                                                                                                                     |                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                     | Path to a cert file for the certificate authority                                                                                                               |

# kubectl api-versions

## Synopsis

Print the supported API versions on the server, in the form of "group/version".

kubectl api-versions

# Examples

```
Print the supported API versions
kubectl api-versions
```

# Options

|                       |
|-----------------------|
| -h, --help            |
| help for api-versions |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                               |

|                                                                        |                                                                                                                                                                 |

# kubectl apply

## Synopsis

Apply a configuration to a resource by file name or stdin. The resource name must be specified. This resource will be created if it doesn't exist yet. To use 'apply', always create the resource initially with either 'apply' or 'create --save-config'.

JSON and YAML formats are accepted.

Alpha Disclaimer: the --prune functionality is not yet complete. Do not use unless you are aware of what the current state is. See <https://issues.k8s.io/34274>.

```
kubectl apply (-f FILENAME | -k DIRECTORY)
```

## Examples

```
Apply the configuration in pod.json to a pod
kubectl apply -f ./pod.json

Apply resources from a directory containing kustomization.yaml - e.g. dir/
kustomization.yaml
kubectl apply -k dir/

Apply the JSON passed into stdin to a pod
cat pod.json | kubectl apply -f -

Apply the configuration from all files that end with '.json'
kubectl apply -f '*.json'

Note: --prune is still in Alpha
Apply the configuration in manifest.yaml that matches label app=nginx and delete all other
resources that are not in the file and match label app=nginx
```

```
kubectl apply --prune -f manifest.yaml -l app=nginx
```

# Apply the configuration in manifest.yaml and delete all the other config maps that are not in the file

```
kubectl apply --prune -f manifest.yaml --all --prune-allowlist=core/v1/ConfigMap
```

## Options

|                                                                                                                                                                                                          |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| <code>--all</code>                                                                                                                                                                                       |  |
| Select all resources in the namespace of the specified resource types.                                                                                                                                   |  |
| <code>--allow-missing-template-keys</code> Default: true                                                                                                                                                 |  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                          |  |
| <code>--cascade string[="background"]</code> Default: "background"                                                                                                                                       |  |
| Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.                      |  |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                              |  |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |  |
| <code>--field-manager string</code> Default: "kubectl-client-side-apply"                                                                                                                                 |  |
| Name of the manager used to track field ownership.                                                                                                                                                       |  |
| <code>-f, --filename strings</code>                                                                                                                                                                      |  |
| The files that contain the configurations to apply.                                                                                                                                                      |  |
| <code>--force</code>                                                                                                                                                                                     |  |
| If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.          |  |
| <code>--force-conflicts</code>                                                                                                                                                                           |  |
| If true, server-side apply will force the changes against conflicts.                                                                                                                                     |  |
| <code>--grace-period int</code> Default: -1                                                                                                                                                              |  |
| Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when --force is true (force deletion).               |  |

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h, --help                                                                                                                                                                 |
| help for apply                                                                                                                                                             |
| -k, --kustomize string                                                                                                                                                     |
| Process a kustomization directory. This flag can't be used together with -f or -R.                                                                                         |
| --openapi-patch    Default: true                                                                                                                                           |
| If true, use openapi to calculate diff when the openapi presents and the resource can be found in the openapi spec. Otherwise, fall back to use baked-in types.            |
| -o, --output string                                                                                                                                                        |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                               |
| --overwrite    Default: true                                                                                                                                               |
| Automatically resolve conflicts between the modified and live configuration by using values from the modified configuration                                                |
| --prune                                                                                                                                                                    |
| Automatically delete resource objects, that do not appear in the configs and are created by either apply or create --save-config. Should be used with either -l or --all.  |
| --prune-allowlist strings                                                                                                                                                  |
| Overwrite the default allowlist with <group/version/kind> for --prune                                                                                                      |
| -R, --recursive                                                                                                                                                            |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                            |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --server-side                                                                                                                                                              |
| If true, apply runs in the server instead of the client.                                                                                                                   |
| --show-managed-fields                                                                                                                                                      |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                              |
| --template string                                                                                                                                                          |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --timeout duration                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --wait                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| If true, wait for resources to be gone before returning. This waits for finalizers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                                                                                                              |

# kubectl apply edit-last-applied

## Synopsis

Edit the latest last-applied-configuration annotations of resources from the default editor.

The edit-last-applied command allows you to directly edit any API resource you can retrieve via the command-line tools. It will open the editor defined by your KUBE\_EDITOR, or EDITOR environment variables, or fall back to 'vi' for Linux or 'notepad' for Windows. You can edit multiple objects, although changes are applied one at a time. The command accepts file names as well as command-line arguments, although the files you point to must be previously saved versions of resources.

The default format is YAML. To edit in JSON, specify "-o json".

The flag `--windows-line-endings` can be used to force Windows line endings, otherwise the default for your operating system will be used.

In the event an error occurs while updating, a temporary file will be created on disk that contains your unapplied changes. The most common error when updating a resource is another editor changing the resource on the server. When this occurs, you will have to apply your changes to the newer version of the resource, or update your temporary saved copy to include the latest resource version.

```
kubectl apply edit-last-applied (RESOURCE/NAME | -f FILENAME)
```

## Examples

```
Edit the last-applied-configuration annotations by type/name in YAML
kubectl apply edit-last-applied deployment/nginx

Edit the last-applied-configuration annotations by file in JSON
kubectl apply edit-last-applied -f deploy.yaml -o json
```

## Options

|                                                                                                                                                 |                                                |
|-------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| <code>--allow-missing-template-keys</code>                                                                                                      | Default: true                                  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |                                                |
| <code>--field-manager</code>                                                                                                                    | string    Default: "kubectl-client-side-apply" |
| Name of the manager used to track field ownership.                                                                                              |                                                |
| <code>-f, --filename</code>                                                                                                                     | strings                                        |
| Filename, directory, or URL to files to use to edit the resource                                                                                |                                                |
| <code>-h, --help</code>                                                                                                                         |                                                |
| help for edit-last-applied                                                                                                                      |                                                |
| <code>-k, --kustomize</code>                                                                                                                    | string                                         |
| Process the kustomization directory. This flag can't be used together with <code>-f</code> or <code>-R</code> .                                 |                                                |
| <code>-o, --output</code>                                                                                                                       | string                                         |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).    |                                                |
| <code>-R, --recursive</code>                                                                                                                    |                                                |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| --show-managed-fields                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                            |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --windows-line-endings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Defaults to the line ending native to your platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |

| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl apply](#) - Apply a configuration to a resource by file name or stdin

# kubectl apply set-last-applied

## Synopsis

Set the latest last-applied-configuration annotations by setting it to match the contents of a file. This results in the last-applied-configuration being updated as though 'kubectl apply -f<file> ' was run, without updating any other parts of the object.

```
kubectl apply set-last-applied -f FILENAME
```

## Examples

```
Set the last-applied-configuration of a resource to match the contents of a file
kubectl apply set-last-applied -f deploy.yaml
```

```
Execute set-last-applied against each configuration file in a directory
kubectl apply set-last-applied -f path/
```

```
Set the last-applied-configuration of a resource to match the contents of a file; will create the
annotation if it does not already exist
kubectl apply set-last-applied -f deploy.yaml --create-annotation=true
```

## Options

|                                                                                                                                                                                                                                                          |                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| --allow-missing-template-keys                                                                                                                                                                                                                            | Default: true   |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                                                                          |                 |
| --create-annotation                                                                                                                                                                                                                                      |                 |
| Will create 'last-applied-configuration' annotations if current objects doesn't have one                                                                                                                                                                 |                 |
| --dry-run string[="unchanged"]                                                                                                                                                                                                                           | Default: "none" |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                 |                 |
| -f, --filename strings                                                                                                                                                                                                                                   |                 |
| Filename, directory, or URL to files that contains the last-applied-configuration annotations                                                                                                                                                            |                 |

| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

## See Also

- [kubectl apply](#) - Apply a configuration to a resource by file name or stdin

# kubectl apply view-last-applied

## Synopsis

View the latest last-applied-configuration annotations by type/name or file.

The default output will be printed to stdout in YAML format. You can use the -o option to change the output format.

kubectl apply view-last-applied (TYPE [NAME | -l label] | TYPE/NAME | -f FILENAME)

## Examples

```
View the last-applied-configuration annotations by type/name in YAML
kubectl apply view-last-applied deployment/nginx

View the last-applied-configuration annotations by file in JSON
kubectl apply view-last-applied -f deploy.yaml -o json
```

## Options

|                        |                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------|
| --all                  |                                                                                               |
|                        | Select all resources in the namespace of the specified resource types                         |
| -f, --filename strings |                                                                                               |
|                        | Filename, directory, or URL to files that contains the last-applied-configuration annotations |
| -h, --help             |                                                                                               |
|                        | help for view-last-applied                                                                    |
| -k, --kustomize string |                                                                                               |
|                        | Process the kustomization directory. This flag can't be used together with -f or -R.          |
| -o, --output string    | Default: "yaml"                                                                               |
|                        | Output format. Must be one of (yaml, json)                                                    |
| -R, --recursive        |                                                                                               |

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                            |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |

- [kubectl apply](#) - Apply a configuration to a resource by file name or stdin

# kubectl attach

## Synopsis

Attach to a process that is already running inside an existing container.

```
kubectl attach (POD | TYPE/NAME) -c CONTAINER
```

## Examples

```
Get output from running pod mypod; use the 'kubectl.kubernetes.io/default-container'
annotation
for selecting the container to be attached or the first container in the pod will be chosen
kubectl attach mypod

Get output from ruby-container from pod mypod
kubectl attach mypod -c ruby-container

Switch to raw terminal mode; sends stdin to 'bash' in ruby-container from pod mypod
and sends stdout/stderr from 'bash' back to the client
kubectl attach mypod -c ruby-container -i -t

Get output from the first pod of a replica set named nginx
kubectl attach rs/nginx
```

## Options

|                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c, --container string                                                                                                                                                             |
| Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen |

|                                                                                                     |
|-----------------------------------------------------------------------------------------------------|
| -h, --help                                                                                          |

| The name of the kubeconfig context to use                                                                                                                       |                                                                       |
| <code>--default-not-ready-toleration-seconds int</code>                                                                                                         | Default: 300                                                          |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |                                                                       |
| <code>--default-unreachable-toleration-seconds int</code>                                                                                                       | Default: 300                                                          |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |                                                                       |
| <code>--disable-compression</code>                                                                                                                              |                                                                       |
| If true, opt-out of response compression for all requests to the server                                                                                         |                                                                       |
| <code>--insecure-skip-tls-verify</code>                                                                                                                         |                                                                       |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |                                                                       |
| <code>--kubeconfig string</code>                                                                                                                                |                                                                       |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |                                                                       |
| <code>--match-server-version</code>                                                                                                                             |                                                                       |
| Require server version to match client version                                                                                                                  |                                                                       |
| <code>-n, --namespace string</code>                                                                                                                             |                                                                       |
| If present, the namespace scope for this CLI request                                                                                                            |                                                                       |
| <code>--password string</code>                                                                                                                                  |                                                                       |
| Password for basic authentication to the API server                                                                                                             |                                                                       |

|                                                                                                                                                                                                   |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --profile string                                                                                                                                                                                  | Default: "none"           |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |                           |
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof"  |
| Name of the file to write the profile to                                                                                                                                                          |                           |
| --request-timeout string                                                                                                                                                                          | Default: "0"              |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                           |
| -s, --server string                                                                                                                                                                               |                           |
| The address and port of the Kubernetes API server                                                                                                                                                 |                           |
| --storage-driver-buffer-duration duration                                                                                                                                                         | Default: 1m0s             |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |                           |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                       |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                     |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | If true, opt-out of response compression for all requests to the server                                                                                                                           |
|  | <code>--insecure-skip-tls-verify</code>                                                                                                                                                           |
|  | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
|  | <code>--kubeconfig string</code>                                                                                                                                                                  |
|  | Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
|  | <code>--match-server-version</code>                                                                                                                                                               |
|  | Require server version to match client version                                                                                                                                                    |
|  | <code>-n, --namespace string</code>                                                                                                                                                               |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | <code>--password string</code>                                                                                                                                                                    |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | <code>--profile string</code> Default: "none"                                                                                                                                                     |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | <code>--profile-output string</code> Default: "profile.pprof"                                                                                                                                     |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | <code>--request-timeout string</code> Default: "0"                                                                                                                                                |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | <code>-s, --server string</code>                                                                                                                                                                  |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                                                                                              |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | <code>--storage-driver-db string</code> Default: "cadvisor"                                                                                                                                       |
|  | database name                                                                                                                                                                                     |
|  | <code>--storage-driver-host string</code> Default: "localhost:8086"                                                                                                                               |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|

| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl auth can-i

## Synopsis

Check whether an action is allowed.

VERB is a logical Kubernetes API verb like 'get', 'list', 'watch', 'delete', etc. TYPE is a Kubernetes resource. Shortcuts and groups will be resolved. NONRESOURCEURL is a partial URL that starts with "/". NAME is the name of a particular Kubernetes resource. This command pairs nicely with impersonation. See --as global flag.

```
kubectl auth can-i VERB [TYPE | TYPE/NAME | NONRESOURCEURL]
```

## Examples

```
Check to see if I can create pods in any namespace
kubectl auth can-i create pods --all-namespaces

Check to see if I can list deployments in my current namespace
kubectl auth can-i list deployments.apps

Check to see if service account "foo" of namespace "dev" can list pods
in the namespace "prod".
You must be allowed to use impersonation for the global option "--as".
kubectl auth can-i list pods --as=system:serviceaccount:dev:foo -n prod

Check to see if I can do everything in my current namespace ("*" means all)
kubectl auth can-i '*' '*'

Check to see if I can get the job named "bar" in namespace "foo"
kubectl auth can-i list jobs.batch/bar -n foo

Check to see if I can read pod logs
kubectl auth can-i get pods --subresource=log

Check to see if I can access the URL /logs/
kubectl auth can-i get /logs/

List all allowed actions in namespace "foo"
kubectl auth can-i --list --namespace=foo
```

## Options

|                      |
|----------------------|
| -A, --all-namespaces |
|----------------------|

|                                                         |
|---------------------------------------------------------|
| If true, check the specified action in all namespaces.  |
| -h, --help                                              |
| help for can-i                                          |
| --list                                                  |
| If true, prints all allowed actions.                    |
| --no-headers                                            |
| If true, prints allowed actions without headers         |
| -q, --quiet                                             |
| If true, suppress output and just return the exit code. |
| --subresource string                                    |
| SubResource such as pod/log or deployment/scale         |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Password for basic authentication to the API server</p>                                                                                                                                               |
| <p>--profile string    Default: "none"</p>                                                                                                                                                               |
| <p>Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)</p>                                                                                                             |
| <p>--profile-output string    Default: "profile.pprof"</p>                                                                                                                                               |
| <p>Name of the file to write the profile to</p>                                                                                                                                                          |
| <p>--request-timeout string    Default: "0"</p>                                                                                                                                                          |
| <p>The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.</p> |
| <p>-s, --server string</p>                                                                                                                                                                               |
| <p>The address and port of the Kubernetes API server</p>                                                                                                                                                 |

# kubectl auth reconcile

## Synopsis

Reconciles rules for RBAC role, role binding, cluster role, and cluster role binding objects.

Missing objects are created, and the containing namespace is created for namespaced objects, if required.

Existing roles are updated to include the permissions in the input objects, and remove extra permissions if --remove-extra-permissions is specified.

Existing bindings are updated to include the subjects in the input objects, and remove extra subjects if --remove-extra-subjects is specified.

This is preferred to 'apply' for RBAC resources so that semantically-aware merging of rules and subjects is done.

```
kubectl auth reconcile -f FILENAME
```

# Examples

```
Reconcile RBAC resources from a file
kubectl auth reconcile -f my-rbac-rules.yaml
```

# Options

|                                                                                                                                                                                                          |                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true   |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                         |                 |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none" |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                 |
| -f, --filename strings                                                                                                                                                                                   |                 |
| Filename, directory, or URL to files identifying the resource to reconcile.                                                                                                                              |                 |
| -h, --help                                                                                                                                                                                               |                 |
| help for reconcile                                                                                                                                                                                       |                 |
| -k, --kustomize string                                                                                                                                                                                   |                 |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                     |                 |
| -o, --output string                                                                                                                                                                                      |                 |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |                 |
| -R, --recursive                                                                                                                                                                                          |                 |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                          |                 |
| --remove-extra-permissions                                                                                                                                                                               |                 |
| If true, removes extra permissions added to roles                                                                                                                                                        |                 |
| --remove-extra-subjects                                                                                                                                                                                  |                 |
| If true, removes extra subjects added to rolebindings                                                                                                                                                    |                 |
| --show-managed-fields                                                                                                                                                                                    |                 |

|                                                                                                                                                                                                                                                           |

| --password string                            |                                                                                                                                                                                                   |
|                                              | Password for basic authentication to the API server                                                                                                                                               |
| --profile string                             | Default: "none"                                                                                                                                                                                   |
|                                              | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-s, --server string</code>                                                                                                  |
| The address and port of the Kubernetes API server                                                                                 |
| <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                              |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| <code>--storage-driver-db string</code> Default: "cadvisor"                                                                       |
| database name                                                                                                                     |
| <code>--storage-driver-host string</code> Default: "localhost:8086"                                                               |
| database host:port                                                                                                                |
| <code>--storage-driver-password string</code> Default: "root"                                                                     |
| database password                                                                                                                 |
| <code>--storage-driver-secure</code>                                                                                              |
| use secure connection with database                                                                                               |
| <code>--storage-driver-table string</code> Default: "stats"                                                                       |
| table name                                                                                                                        |
| <code>--storage-driver-user string</code> Default: "root"                                                                         |
| database username                                                                                                                 |
| <code>--tls-server-name string</code>                                                                                             |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| <code>--token string</code>                                                                                                       |
| Bearer token for authentication to the API server                                                                                 |
| <code>--user string</code>                                                                                                        |
| The name of the kubeconfig user to use                                                                                            |
| <code>--username string</code>                                                                                                    |
| Username for basic authentication to the API server                                                                               |
| <code>--version version[=true]</code>                                                                                             |

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>--version, --version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
|----------------------------------------------------------------------------------------------------------------------------------------|

|                                   |
|-----------------------------------|
| <code>--warnings-as-errors</code> |
|-----------------------------------|

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

## See Also

- [kubectl auth](#) - Inspect authorization

# kubectl auth whoami

## Synopsis

Experimental: Check who you are and your attributes (groups, extra).

This command is helpful to get yourself aware of the current user attributes, especially when dynamic authentication, e.g., token webhook, auth proxy, or OIDC provider, is enabled in the Kubernetes cluster.

`kubectl auth whoami`

## Examples

# Get your subject attributes.

`kubectl auth whoami`

# Get your subject attributes in JSON format.

`kubectl auth whoami -o json`

## Options

|                                                          |
|----------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true |
|----------------------------------------------------------|

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
|-------------------------------------------------------------------------------------------------------------------------------------------------|

|                         |

# kubectl autoscale

## Synopsis

Creates an autoscaler that automatically chooses and sets the number of pods that run in a Kubernetes cluster.

Looks up a deployment, replica set, stateful set, or replication controller by name and creates an autoscaler that uses the given resource as a reference. An autoscaler can automatically increase or decrease number of pods deployed within the system as needed.

```
kubectl autoscale (-f FILENAME | TYPE NAME | TYPE/NAME) [--min=MINPODS] --max=MAXPODS [--cpu-percent=CPU]
```

## Examples

```
Auto scale a deployment "foo", with the number of pods between 2 and 10, no target CPU utilization specified so a default autoscaling policy will be used
```

```
kubectl autoscale deployment foo --min=2 --max=10
```

```
Auto scale a replication controller "foo", with the number of pods between 1 and 5, target CPU utilization at 80%
```

```
kubectl autoscale rc foo --max=5 --cpu-percent=80
```

## Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-missing-template-keys    Default: true                                                                                                  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
| --cpu-percent int32    Default: -1                                                                                                              |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The target average CPU utilization (represented as a percent of requested CPU) over all the pods. If it's not specified or negative, a default autoscaling policy will be used.                          |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-autoscale"                                                                                                                                                   |
| Name of the manager used to track field ownership.                                                                                                                                                       |
| -f, --filename strings                                                                                                                                                                                   |
| Filename, directory, or URL to files identifying the resource to autoscale.                                                                                                                              |
| -h, --help                                                                                                                                                                                               |
| help for autoscale                                                                                                                                                                                       |
| -k, --kustomize string                                                                                                                                                                                   |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                     |
| --max int32    Default: -1                                                                                                                                                                               |
| The upper limit for the number of pods that can be set by the autoscaler. Required.                                                                                                                      |
| --min int32    Default: -1                                                                                                                                                                               |
| The lower limit for the number of pods that can be set by the autoscaler. If it's not specified or negative, the server will apply a default value.                                                      |
| --name string                                                                                                                                                                                            |
| The name for the newly created object. If not specified, the name of the input resource will be used.                                                                                                    |
| -o, --output string                                                                                                                                                                                      |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                             |
| -R, --recursive                                                                                                                                                                                          |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                          |
| --save-config                                                                                                                                                                                            |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                      |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                           |                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                  | Default: "0"                                                                                                                                                                                      |
|                                           | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                       |                                                                                                                                                                                                   |
|                                           | The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration | Default: 1m0s                                                                                                                                                                                     |
|                                           | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string                | Default: "cadvisor"                                                                                                                                                                               |
|                                           | database name                                                                                                                                                                                     |
| --storage-driver-host string              | Default: "localhost:8086"                                                                                                                                                                         |
|                                           | database host:port                                                                                                                                                                                |
| --storage-driver-password string          | Default: "root"                                                                                                                                                                                   |

# kubectl certificate approve

## Synopsis

Approve a certificate signing request.

kubectl certificate approve allows a cluster admin to approve a certificate signing request (CSR). This action tells a certificate signing controller to issue a certificate to the requester with the attributes requested in the CSR.

SECURITY NOTICE: Depending on the requested attributes, the issued certificate can potentially grant a requester access to cluster resources or to authenticate as a requested identity. Before approving a CSR, ensure you understand what the signed certificate can do.

kubectl certificate approve (-f FILENAME | NAME)

## Examples

```
Approve CSR 'csr-sqgzp'
kubectl certificate approve csr-sqgzp
```

## Options

|                                                                                                                                                 |               |
|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| --allow-missing-template-keys                                                                                                                   | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats. |               |
| -f, --filename strings                                                                                                                          |               |
| Filename, directory, or URL to files identifying the resource to update                                                                         |               |
| --force                                                                                                                                         |               |
| Update the CSR even if it is already approved.                                                                                                  |               |
| -h, --help                                                                                                                                      |               |
| help for approve                                                                                                                                |               |
| -k, --kustomize string                                                                                                                          |               |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                            |               |
| -o, --output string                                                                                                                             |               |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).    |               |
| -R, --recursive                                                                                                                                 |               |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory. |               |
| --show-managed-fields                                                                                                                           |               |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --as string                                                                                                                                                                                                                                               |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                              |
| --as-group strings                                                                                                                                                                                                                                        |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                                                                                                             |
| --as-uid string                                                                                                                                                                                                                                           |
| UID to impersonate for the operation.                                                                                                                                                                                                                     |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                                                                                                                        |
| Default cache directory                                                                                                                                                                                                                                   |

# kubectl certificate deny

## Synopsis

Deny a certificate signing request.

`kubectl certificate deny` allows a cluster admin to deny a certificate signing request (CSR). This action tells a certificate signing controller to not to issue a certificate to the requester.

`kubectl certificate deny (-f FILENAME | NAME)`

## Examples

```
Deny CSR 'csr-sqgzp'
kubectl certificate deny csr-sqgzp
```

## Options

|                                                                                                                                                 |               |
|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| <code>--allow-missing-template-keys</code>                                                                                                      | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |               |
| <code>-f, --filename</code>                                                                                                                     | strings       |
| Filename, directory, or URL to files identifying the resource to update                                                                         |               |
| <code>--force</code>                                                                                                                            |               |
| Update the CSR even if it is already denied.                                                                                                    |               |
| <code>-h, --help</code>                                                                                                                         |               |
| help for deny                                                                                                                                   |               |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -k, --kustomize string                                                                                                                                                                                                                                    |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                                                      |
| -o, --output string                                                                                                                                                                                                                                       |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                              |
| -R, --recursive                                                                                                                                                                                                                                           |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                           |
| --show-managed-fields                                                                                                                                                                                                                                     |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Password for basic authentication to the API server</p>                                                                                                                                               |
| <p>--profile string   Default: "none"</p>                                                                                                                                                                |
| <p>Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)</p>                                                                                                             |
| <p>--profile-output string   Default: "profile.pprof"</p>                                                                                                                                                |
| <p>Name of the file to write the profile to</p>                                                                                                                                                          |
| <p>--request-timeout string   Default: "0"</p>                                                                                                                                                           |
| <p>The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.</p> |

# kubectl cluster-info

## Synopsis

Display addresses of the control plane and services with label `kubernetes.io/cluster-service=true`. To further debug and diagnose cluster problems, use `'kubectl cluster-info dump'`.

```
kubectl cluster-info [flags]
```

## Examples

```
Print the address of the control plane and cluster services
kubectl cluster-info
```

## Options

```
-h, --help
```

|                       |

# kubectl cluster-info dump

## Synopsis

Dump cluster information out suitable for debugging and diagnosing cluster problems. By default, dumps everything to stdout. You can optionally specify a directory with `--output-directory`. If you specify a directory, Kubernetes will build a set of files in that directory. By default, only dumps things in the current namespace and 'kube-system' namespace, but you can switch to a different namespace with the `--namespaces` flag, or specify `--all-namespaces` to dump all namespaces.

The command also dumps the logs of all of the pods in the cluster; these logs are dumped into different directories based on namespace and pod name.

```
kubectl cluster-info dump [flags]
```

## Examples

```
Dump current cluster state to stdout
kubectl cluster-info dump

Dump current cluster state to /path/to/cluster-state
kubectl cluster-info dump --output-directory=/path/to/cluster-state

Dump all namespaces to stdout
kubectl cluster-info dump --all-namespaces

Dump a set of namespaces to /path/to/cluster-state
kubectl cluster-info dump --namespaces default,kube-system --output-directory=/path/to/cluster-state
```

## Options

|                                                                 |
|-----------------------------------------------------------------|
| -A, --all-namespaces                                            |
| If true, dump all namespaces. If true, --namespaces is ignored. |
| --allow-missing-template-keys    Default: true                  |

|                                |                                                                                                                                                                                                                                                          |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                          |
| -h, --help                     |                                                                                                                                                                                                                                                          |
|                                | help for dump                                                                                                                                                                                                                                            |

|  | Require server version to match client version                                                                                                                                                    |
|  | -n, --namespace string                                                                                                                                                                            |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | --password string                                                                                                                                                                                 |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | --profile string   Default: "none"                                                                                                                                                                |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | --profile-output string   Default: "profile.pprof"                                                                                                                                                |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | --request-timeout string   Default: "0"                                                                                                                                                           |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | -s, --server string                                                                                                                                                                               |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
|  | database name                                                                                                                                                                                     |
|  | --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
|  | database host:port                                                                                                                                                                                |
|  | --storage-driver-password string   Default: "root"                                                                                                                                                |
|  | database password                                                                                                                                                                                 |
|  | --storage-driver-secure                                                                                                                                                                           |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl completion

## Synopsis

Output shell completion code for the specified shell (bash, zsh, fish, or powershell). The shell code must be evaluated to provide interactive completion of kubectl commands. This can be done by sourcing it from the .bash\_profile.

Detailed instructions on how to do this are available here:

```
for macOS:
https://kubernetes.io/docs/tasks/tools/install-kubectl-macos/#enable-shell-autocompletion

for linux:
https://kubernetes.io/docs/tasks/tools/install-kubectl-linux/#enable-shell-autocompletion

for windows:
https://kubernetes.io/docs/tasks/tools/install-kubectl-windows/#enable-shell-autocompletion
```

Note for zsh users: [1] zsh completions are only supported in versions of zsh >= 5.2.

kubectl completion SHELL

## Examples

```
Installing bash completion on macOS using homebrew
If running Bash 3.2 included with macOS
brew install bash-completion
or, if running Bash 4.1+
brew install bash-completion@2
If kubectl is installed via homebrew, this should start working immediately
If you've installed via other means, you may need add the completion to your completion
directory
kubectl completion bash > $(brew --prefix)/etc/bash_completion.d/kubectl
```

```
Installing bash completion on Linux
If bash-completion is not installed on Linux, install the 'bash-completion' package
via your distribution's package manager.
Load the kubectl completion code for bash into the current shell
source <(kubectl completion bash)
Write bash completion code to a file and source it from .bash_profile
kubectl completion bash > ~/.kube/completion.bash.inc
printf "
kubectl shell completion
source '$HOME/.kube/completion.bash.inc'
" >> $HOME/.bash_profile
source $HOME/.bash_profile
```

```
Load the kubectl completion code for zsh[1] into the current shell
source <(kubectl completion zsh)
Set the kubectl completion code for zsh[1] to autoload on startup
kubectl completion zsh > "${fpath[1]}/_kubectl"
```

```
Load the kubectl completion code for fish[2] into the current shell
kubectl completion fish | source
To load completions for each session, execute once:
kubectl completion fish > ~/.config/fish/completions/kubectl.fish
```

```
Load the kubectl completion code for powershell into the current shell
kubectl completion powershell | Out-String | Invoke-Expression
Set kubectl completion code for powershell to run on startup
Save completion code to a script and execute in the profile
kubectl completion powershell > $HOME\.kube\completion.ps1
Add-Content $PROFILE "$HOME\.kube\completion.ps1"
Execute completion code in the profile
Add-Content $PROFILE "if (Get-Command kubectl -ErrorAction SilentlyContinue) {
kubectl completion powershell | Out-String | Invoke-Expression
}"
Add completion code directly to the $PROFILE script
kubectl completion powershell >> $PROFILE
```

## Options

|                     |
|---------------------|
| -h, --help          |
| help for completion |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                            |

|                                                                                                                                                                 |

| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                                                                                 |
| table name                                                                                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                                                                                   |
| database username                                                                                                                                                                                 |
| --tls-server-name string                                                                                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                                                                                                                                                                                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| Bearer token for authentication to the API server                                                            |
| --user string                                                                                                |
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

# kubectrl config

## Synopsis

Modify kubeconfig files using subcommands like "kubectrl config set current-context my-context".

The loading order follows these rules:

1. If the --kubeconfig flag is set, then only that file is loaded. The flag may only be set once and no merging takes place.
2. If \$KUBECONFIG environment variable is set, then it is used as a list of paths (normal path delimiting rules for your system). These paths are merged. When a value is modified, it is modified in the file that defines the stanza. When a value is created, it is created in the first file that exists. If no files in the chain exist, then it creates the last file in the list.
3. Otherwise, \${HOME}/.kube/config is used and no merging takes place.

kubectrl config SUBCOMMAND

## Options

|            |
|------------|
| -h, --help |
|------------|

|                                  |
|----------------------------------|
| help for config                  |
| --kubeconfig string              |
| use a particular kubeconfig file |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |

# kubectl config current-context

## Synopsis

Display the current-context.

```
kubectl config current-context [flags]
```

## Examples

```
Display the current-context
kubectl config current-context
```

## Options

| <code>--default-not-ready-toleration-seconds int</code> Default: 300                                                          |                                                                                                                                                                 |
|                                                                                                                               | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| <code>--default-unreachable-toleration-seconds int</code> Default: 300                                                        |                                                                                                                                                                 |
|                                                                                                                               | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| <code>--disable-compression</code>                                                                                            |                                                                                                                                                                 |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | If true, opt-out of response compression for all requests to the server                                                                                                                           |
|  | --insecure-skip-tls-verify                                                                                                                                                                        |
|  | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
|  | --kubeconfig string                                                                                                                                                                               |
|  | use a particular kubeconfig file                                                                                                                                                                  |
|  | --match-server-version                                                                                                                                                                            |
|  | Require server version to match client version                                                                                                                                                    |
|  | -n, --namespace string                                                                                                                                                                            |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | --password string                                                                                                                                                                                 |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | --profile string   Default: "none"                                                                                                                                                                |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | --profile-output string   Default: "profile.pprof"                                                                                                                                                |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | --request-timeout string   Default: "0"                                                                                                                                                           |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | -s, --server string                                                                                                                                                                               |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
|  | database name                                                                                                                                                                                     |
|  | --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database host:port                                                                                                           |
| --storage-driver-password string    Default: "root"                                                                          |
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl config delete-cluster

## Synopsis

Delete the specified cluster from the kubeconfig.

```
kubectl config delete-cluster NAME
```

## Examples

```
Delete the minikube cluster
kubectl config delete-cluster minikube
```

## Options

|                         |
|-------------------------|
| -h, --help              |
| help for delete-cluster |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| use a particular kubeconfig file                                                                                                                                |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |

|                                                                                                                                                                                                   |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --profile string                                                                                                                                                                                  | Default: "none"           |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |                           |
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof"  |
| Name of the file to write the profile to                                                                                                                                                          |                           |
| --request-timeout string                                                                                                                                                                          | Default: "0"              |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                           |
| -s, --server string                                                                                                                                                                               |                           |
| The address and port of the Kubernetes API server                                                                                                                                                 |                           |
| --storage-driver-buffer-duration duration                                                                                                                                                         | Default: 1m0s             |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |                           |
| --storage-driver-db string                                                                                                                                                                        | Default: "cadvisor"       |
| database name                                                                                                                                                                                     |                           |
| --storage-driver-host string                                                                                                                                                                      | Default: "localhost:8086" |
| database host:port                                                                                                                                                                                |                           |
| --storage-driver-password string                                                                                                                                                                  | Default: "root"           |
| database password                                                                                                                                                                                 |                           |
| --storage-driver-secure                                                                                                                                                                           |                           |
| use secure connection with database                                                                                                                                                               |                           |
| --storage-driver-table string                                                                                                                                                                     | Default: "stats"          |
| table name                                                                                                                                                                                        |                           |
| --storage-driver-user string                                                                                                                                                                      | Default: "root"           |
| database username                                                                                                                                                                                 |                           |
| --tls-server-name string                                                                                                                                                                          |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |                           |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --token string                                                                                               |
| Bearer token for authentication to the API server                                                            |
| --user string                                                                                                |
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

# kubectl config delete-context

## Synopsis

Delete the specified context from the kubeconfig.

```
kubectl config delete-context NAME
```

## Examples

```
Delete the context for the minikube cluster
kubectl config delete-context minikube
```

| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| use a particular kubeconfig file                                                                                                                                                                  |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

# kubectl config delete-user

## Synopsis

Delete the specified user from the kubeconfig.

```
kubectl config delete-user NAME
```

## Examples

```
Delete the minikube user
kubectl config delete-user minikube
```

## Options

|                      |
|----------------------|
| -h, --help           |
| help for delete-user |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| use a particular kubeconfig file                                                                                                                                |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl config get-clusters

## Synopsis

Display clusters defined in the kubeconfig.

```
kubectl config get-clusters [flags]
```

## Examples

```
List the clusters that kubectl knows about
kubectl config get-clusters
```

# Options

|                       |
|-----------------------|
| -h, --help            |
| help for get-clusters |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                               |
| --cluster string                                                                                                   |
| The name of the kubeconfig cluster to use                                                                          |
| --context string                                                                                                   |

|                                              |                                                                                                                                                                                                   |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | The name of the kubeconfig context to use                                                                                                                                                         |
| --default-not-ready-toleration-seconds int   | Default: 300                                                                                                                                                                                      |
|                                              | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int | Default: 300                                                                                                                                                                                      |
|                                              | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                        |                                                                                                                                                                                                   |
|                                              | If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                   |                                                                                                                                                                                                   |
|                                              | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                          |                                                                                                                                                                                                   |
|                                              | use a particular kubeconfig file                                                                                                                                                                  |
| --match-server-version                       |                                                                                                                                                                                                   |
|                                              | Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                       |                                                                                                                                                                                                   |
|                                              | If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                            |                                                                                                                                                                                                   |
|                                              | Password for basic authentication to the API server                                                                                                                                               |
| --profile string                             | Default: "none"                                                                                                                                                                                   |
|                                              | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-s, --server string</code>                                                                                                  |
| The address and port of the Kubernetes API server                                                                                 |
| <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                              |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| <code>--storage-driver-db string</code> Default: "cadvisor"                                                                       |
| database name                                                                                                                     |
| <code>--storage-driver-host string</code> Default: "localhost:8086"                                                               |
| database host:port                                                                                                                |
| <code>--storage-driver-password string</code> Default: "root"                                                                     |
| database password                                                                                                                 |
| <code>--storage-driver-secure</code>                                                                                              |
| use secure connection with database                                                                                               |
| <code>--storage-driver-table string</code> Default: "stats"                                                                       |
| table name                                                                                                                        |
| <code>--storage-driver-user string</code> Default: "root"                                                                         |

- [kubectl config](#) - Modify kubeconfig files

# kubectl config get-contexts

## Synopsis

Display one or many contexts from the kubeconfig file.

```
kubectl config get-contexts [(-o|--output=)name)]
```

## Examples

```
List all the contexts in your kubeconfig file
kubectl config get-contexts
```

```
Describe one context in your kubeconfig file
kubectl config get-contexts my-context
```

|                                                                                                     |
|-----------------------------------------------------------------------------------------------------|
| When using the default or custom-column output format, don't print headers (default print headers). |
|-----------------------------------------------------------------------------------------------------|

|                                  |
|----------------------------------|
| <code>-o, --output string</code> |
|----------------------------------|

|                                |
|--------------------------------|
| Output format. One of: (name). |
|--------------------------------|

|                          |
|--------------------------|
| <code>--as string</code> |
|--------------------------|

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |
| --as-uid string                                                                                                                                              |
| UID to impersonate for the operation.                                                                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                           |
| Default cache directory                                                                                                                                      |
| --certificate-authority string                                                                                                                               |
| Path to a cert file for the certificate authority                                                                                                            |
| --client-certificate string                                                                                                                                  |
| Path to a client certificate file for TLS                                                                                                                    |
| --client-key string                                                                                                                                          |
| Path to a client key file for TLS                                                                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                            |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                         |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                           |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                         |
| --cluster string                                                                                                                                             |
| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| use a particular kubeconfig file                                                                                                                                                                  |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

# kubectl config get-users

## Synopsis

Display users defined in the kubeconfig.

```
kubectl config get-users [flags]
```

## Examples

```
List the users that kubectl knows about
kubectl config get-users
```

## Options

|                    |
|--------------------|
| -h, --help         |
| help for get-users |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| use a particular kubeconfig file                                                                                                                                |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

- [kubectl config](#) - Modify kubeconfig files

# kubectl config rename-context

## Synopsis

Renames a context from the kubeconfig file.

CONTEXT\_NAME is the context name that you want to change.

NEW\_NAME is the new name you want to set.

Note: If the context being renamed is the 'current-context', this field will also be updated.

```
kubectl config rename-context CONTEXT_NAME NEW_NAME
```

# Examples

```
Rename the context 'old-name' to 'new-name' in your kubeconfig file
kubectl config rename-context old-name new-name
```

| The name of the kubeconfig user to use                                                                                                                                                            |
| <code>--username string</code>                                                                                                                                                                    |

|                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username for basic authentication to the API server                                                                                                  |
| <code>--version version[=true]</code>                                                                                                                |
| <code>--version</code> , <code>--version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
| <code>--warnings-as-errors</code>                                                                                                                    |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                                                 |

## See Also

- [kubectl config](#) - Modify kubeconfig files

# kubectl config set

## Synopsis

Set an individual value in a kubeconfig file.

PROPERTY\_NAME is a dot delimited name where each token represents either an attribute name or a map key. Map keys may not contain dots.

PROPERTY\_VALUE is the new value you want to set. Binary fields such as 'certificate-authority-data' expect a base64 encoded string unless the `--set-raw-bytes` flag is used.

Specifying an attribute name that already exists will merge new fields on top of existing values.

```
kubectl config set PROPERTY_NAME PROPERTY_VALUE
```

## Examples

```
Set the server field on the my-cluster cluster to https://1.2.3.4
kubectl config set clusters.my-cluster.server https://1.2.3.4

Set the certificate-authority-data field on the my-cluster cluster
kubectl config set clusters.my-cluster.certificate-authority-data $(echo "cert_data_here" |
base64 -i -)

Set the cluster field in the my-context context to my-cluster
kubectl config set contexts.my-context.cluster my-cluster

Set the client-key-data field in the cluster-admin user using --set-raw-bytes option
kubectl config set users.cluster-admin.client-key-data cert_data_here --set-raw-bytes=true
```

- [kubectl config](#) - Modify kubeconfig files

# kubectl config set-cluster

## Synopsis

Set a cluster entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values for those fields.

```
kubectl config set-cluster NAME [--server=server] [--certificate-authority=path/to/certificate/authority] [--insecure-skip-tls-verify=true] [--tls-server-name=example.com]
```

## Examples

```
Set only the server field on the e2e cluster entry without touching other values
kubectl config set-cluster e2e --server=https://1.2.3.4

Embed certificate authority data for the e2e cluster entry
kubectl config set-cluster e2e --embed-certs --certificate-authority=~/.kube/e2e/
kubernetes.ca.crt

Disable cert checking for the e2e cluster entry
kubectl config set-cluster e2e --insecure-skip-tls-verify=true

Set the custom TLS server name to use for validation for the e2e cluster entry
kubectl config set-cluster e2e --tls-server-name=my-cluster-name

Set the proxy URL for the e2e cluster entry
kubectl config set-cluster e2e --proxy-url=https://1.2.3.4
```

## Options

|                                                                        |
|------------------------------------------------------------------------|
| --certificate-authority string                                         |
| Path to certificate-authority file for the cluster entry in kubeconfig |
| --embed-certs tristate[=true]                                          |
| embed-certs for the cluster entry in kubeconfig                        |
| -h, --help                                                             |
| help for set-cluster                                                   |
| --insecure-skip-tls-verify tristate[=true]                             |
| insecure-skip-tls-verify for the cluster entry in kubeconfig           |
| --proxy-url string                                                     |
| proxy-url for the cluster entry in kubeconfig                          |
| --server string                                                        |
| server for the cluster entry in kubeconfig                             |
| --tls-server-name string                                               |
| tls-server-name for the cluster entry in kubeconfig                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --kubeconfig string                                                                                                                                             |
| use a particular kubeconfig file                                                                                                                                |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string    Default: "none"                                                                                                                                                               |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                                                                                 |
| table name                                                                                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                                                                                   |
| database username                                                                                                                                                                                 |
| --token string                                                                                                                                                                                    |
| Bearer token for authentication to the API server                                                                                                                                                 |
| --user string                                                                                                                                                                                     |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

## See Also

- [kubectl config](#) - Modify kubeconfig files

# kubectl config set-context

## Synopsis

Set a context entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values for those fields.

```
kubectl config set-context [NAME | --current] [--cluster=cluster_nickname] [--user=user_nickname] [--namespace=namespace]
```

## Examples

```
Set the user field on the gce context entry without touching other values
kubectl config set-context gce --user=cluster-admin
```

## Options

|                                             |
|---------------------------------------------|
| --cluster string                            |
| cluster for the context entry in kubeconfig |
| --current                                   |
| Modify the current context                  |

|                                               |
|-----------------------------------------------|
| -h, --help                                    |
| help for set-context                          |
| --namespace string                            |
| namespace for the context entry in kubeconfig |
| --user string                                 |
| user for the context entry in kubeconfig      |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |

- [kubectl config](#) - Modify kubeconfig files

# kubectl config set-credentials

## Synopsis

Set a user entry in kubeconfig.

Specifying a name that already exists will merge new fields on top of existing values.

Client-certificate flags:

--client-certificate=certfile --client-key=keyfile

Bearer token flags:

--token=bearer\_token

Basic auth flags:

--username=basic\_user --password=basic\_password

Bearer token and basic auth are mutually exclusive.

```
kubectl config set-credentials NAME [--client-certificate=path/to/certfile] [--client-key=path/to/keyfile] [--token=bearer_token] [--username=basic_user] [--password=basic_password] [--auth-provider=provider_name] [--auth-provider-arg=key=value] [--exec-command=exec_command] [--exec-api-version=exec_api_version] [--exec-arg=arg] [--exec-env=key=value]
```

## Examples

```
Set only the "client-key" field on the "cluster-admin"
entry, without touching other values
kubectl config set-credentials cluster-admin --client-key=~/.kube/admin.key

Set basic auth for the "cluster-admin" entry
kubectl config set-credentials cluster-admin --username=admin --password=uXFGweU9l35qcif

Embed client certificate data in the "cluster-admin" entry
kubectl config set-credentials cluster-admin --client-certificate=~/.kube/admin.crt --embed-certs=true

Enable the Google Compute Platform auth provider for the "cluster-admin" entry
kubectl config set-credentials cluster-admin --auth-provider=gcp

Enable the OpenID Connect auth provider for the "cluster-admin" entry with additional
arguments
```

```

kubectrl config set-credentials cluster-admin --auth-provider=oidc --auth-provider-arg=client-id=foo --auth-provider-arg=client-secret=bar

Remove the "client-secret" config value for the OpenID Connect auth provider for the "cluster-admin" entry
kubectrl config set-credentials cluster-admin --auth-provider=oidc --auth-provider-arg=client-secret-

Enable new exec auth plugin for the "cluster-admin" entry
kubectrl config set-credentials cluster-admin --exec-command=/path/to/the/executable --exec-api-version=client.authentication.k8s.io/v1beta1

Enable new exec auth plugin for the "cluster-admin" entry with interactive mode
kubectrl config set-credentials cluster-admin --exec-command=/path/to/the/executable --exec-api-version=client.authentication.k8s.io/v1beta1 --exec-interactive-mode=Never

Define new exec auth plugin arguments for the "cluster-admin" entry
kubectrl config set-credentials cluster-admin --exec-arg=arg1 --exec-arg=arg2

Create or update exec auth plugin environment variables for the "cluster-admin" entry
kubectrl config set-credentials cluster-admin --exec-env=key1=val1 --exec-env=key2=val2

Remove exec auth plugin environment variables for the "cluster-admin" entry
kubectrl config set-credentials cluster-admin --exec-env=var-to-remove-

```

## Options

|                               |                                                                            |
|-------------------------------|----------------------------------------------------------------------------|
| --auth-provider string        |                                                                            |
|                               | Auth provider for the user entry in kubeconfig                             |
| --auth-provider-arg strings   |                                                                            |
|                               | 'key=value' arguments for the auth provider                                |

| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| use a particular kubeconfig file                                                                                                                                |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --profile string    Default: "none"                                                                                                                                                               |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl config](#) - Modify kubeconfig files

# kubectl config unset

## Synopsis

Unset an individual value in a kubeconfig file.

PROPERTY\_NAME is a dot delimited name where each token represents either an attribute name or a map key. Map keys may not contain dots.

```
kubectl config unset PROPERTY_NAME
```

## Examples

```
Unset the current-context
kubectl config unset current-context

Unset namespace in foo context
kubectl config unset contexts.foo.namespace
```

## Options

|                |

| The name of the kubeconfig cluster to use                                                                                                                    |
| --context string                                                                                                                                             |
| The name of the kubeconfig context to use                                                                                                                    |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |

|                                                                                                                                                                                                   |                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| --default-unreachable-toleration-seconds int                                                                                                                                                      | Default: 300             |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |                          |
| --disable-compression                                                                                                                                                                             |                          |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |                          |
| --insecure-skip-tls-verify                                                                                                                                                                        |                          |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |                          |
| --kubeconfig string                                                                                                                                                                               |                          |
| use a particular kubeconfig file                                                                                                                                                                  |                          |
| --match-server-version                                                                                                                                                                            |                          |
| Require server version to match client version                                                                                                                                                    |                          |
| -n, --namespace string                                                                                                                                                                            |                          |
| If present, the namespace scope for this CLI request                                                                                                                                              |                          |
| --password string                                                                                                                                                                                 |                          |
| Password for basic authentication to the API server                                                                                                                                               |                          |
| --profile string                                                                                                                                                                                  | Default: "none"          |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |                          |
| --profile-output string                                                                                                                                                                           | Default: "profile.pprof" |
| Name of the file to write the profile to                                                                                                                                                          |                          |
| --request-timeout string                                                                                                                                                                          | Default: "0"             |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |                          |
| -s, --server string                                                                                                                                                                               |                          |
| The address and port of the Kubernetes API server                                                                                                                                                 |                          |
| --storage-driver-buffer-duration duration                                                                                                                                                         | Default: 1m0s            |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

Treat warnings received from the server as errors and exit with a non-zero exit code

- [kubectl config](#) - Modify kubeconfig files

# kubectl config use-context

## Synopsis

Set the current-context in a kubeconfig file.

```
kubectl config use-context CONTEXT_NAME
```

## Examples

```
Use the context for the minikube cluster
kubectl config use-context minikube
```

## Options

|                      |
|----------------------|
| -h, --help           |
| help for use-context |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |

|  |                                                                                                                                                                 |
|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Path to a cert file for the certificate authority                                                                                                               |
|  | --client-certificate string                                                                                                                                     |
|  | Path to a client certificate file for TLS                                                                                                                       |
|  | --client-key string                                                                                                                                             |
|  | Path to a client key file for TLS                                                                                                                               |
|  | --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
|  | CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
|  | --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
|  | CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
|  | --cluster string                                                                                                                                                |
|  | The name of the kubeconfig cluster to use                                                                                                                       |
|  | --context string                                                                                                                                                |
|  | The name of the kubeconfig context to use                                                                                                                       |
|  | --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
|  | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
|  | --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
|  | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
|  | --disable-compression                                                                                                                                           |
|  | If true, opt-out of response compression for all requests to the server                                                                                         |
|  | --insecure-skip-tls-verify                                                                                                                                      |
|  | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
|  | --kubeconfig string                                                                                                                                             |
|  | use a particular kubeconfig file                                                                                                                                |
|  | --match-server-version                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Require server version to match client version                                                                                                                                                    |
| <code>-n, --namespace string</code>                                                                                                                                                               |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| <code>--password string</code>                                                                                                                                                                    |
| Password for basic authentication to the API server                                                                                                                                               |
| <code>--profile string</code> Default: "none"                                                                                                                                                     |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| <code>--profile-output string</code> Default: "profile.pprof"                                                                                                                                     |
| Name of the file to write the profile to                                                                                                                                                          |
| <code>--request-timeout string</code> Default: "0"                                                                                                                                                |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| <code>-s, --server string</code>                                                                                                                                                                  |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                                                                                              |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| <code>--storage-driver-db string</code> Default: "cadvisor"                                                                                                                                       |
| database name                                                                                                                                                                                     |
| <code>--storage-driver-host string</code> Default: "localhost:8086"                                                                                                                               |
| database host:port                                                                                                                                                                                |
| <code>--storage-driver-password string</code> Default: "root"                                                                                                                                     |
| database password                                                                                                                                                                                 |
| <code>--storage-driver-secure</code>                                                                                                                                                              |
| use secure connection with database                                                                                                                                                               |
| <code>--storage-driver-table string</code> Default: "stats"                                                                                                                                       |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl config](#) - Modify kubeconfig files

# kubectl config view

## Synopsis

Display merged kubeconfig settings or a specified kubeconfig file.

You can use --output jsonpath={...} to extract specific values using a jsonpath expression.

kubectl config view [flags]

## Examples

```
Show merged kubeconfig settings
kubectl config view

Show merged kubeconfig settings, raw certificate data, and exposed secrets
kubectl config view --raw

Get the password for the e2e user
kubectl config view -o jsonpath='{.users[?(@.name == "e2e")].user.password}'
```

|-------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| --allow-missing-template-keys                                                                                                                   | Default: true   |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |                 |
| --flatten                                                                                                                                       |                 |
| Flatten the resulting kubeconfig file into self-contained output (useful for creating portable kubeconfig files)                                |                 |
| -h, --help                                                                                                                                      |                 |
| help for view                                                                                                                                   |                 |
| --merge tristate[=true]                                                                                                                         | Default: true   |
| Merge the full hierarchy of kubeconfig files                                                                                                    |                 |
| --minify                                                                                                                                        |                 |
| Remove all information not used by current-context from the output                                                                              |                 |
| -o, --output string                                                                                                                             | Default: "yaml" |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).    |                 |
| --raw                                                                                                                                           |                 |
| Display raw byte data and sensitive data                                                                                                        |                 |
| --show-managed-fields                                                                                                                           |                 |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                   |                 |
| --template string                                                                                                                               |                 |

Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [<http://golang.org/pkg/text/template/#pkg-overview>].

--as string

Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

--as-group strings

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.

--as-uid string

UID to impersonate for the operation.

--cache-dir string Default: "\$HOME/.kube/cache"

Default cache directory

--certificate-authority string

Path to a cert file for the certificate authority

--client-certificate string

Path to a client certificate file for TLS

--client-key string

Path to a client key file for TLS

--cloud-provider-gce-l7lb-src-cidrs cidrs Default: 130.211.0.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks

--cloud-provider-gce-lb-src-cidrs cidrs Default:  
130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks

--cluster string

The name of the kubeconfig cluster to use

--context string

The name of the kubeconfig context to use

--default-not-ready-toleration-seconds int Default: 300

|                                              |                                                                                                                                                                                                   |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int | Default: 300                                                                                                                                                                                      |
|                                              | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                        |                                                                                                                                                                                                   |
|                                              | If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                   |                                                                                                                                                                                                   |
|                                              | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                          |                                                                                                                                                                                                   |
|                                              | use a particular kubeconfig file                                                                                                                                                                  |
| --match-server-version                       |                                                                                                                                                                                                   |
|                                              | Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                       |                                                                                                                                                                                                   |
|                                              | If present, the namespace scope for this CLI request                                                                                                                                              |

|                                              | Password for basic authentication to the API server                                                                                                                                               |
| --profile string                             | Default: "none"                                                                                                                                                                                   |
|                                              | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                          |                                                                                                                                                                                                   |
|                                              | The address and port of the Kubernetes API server                                                                                                                                                 |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

# kubectl cordon

## Synopsis

Mark node as unschedulable.

```
kubectl cordon NODE
```

## Examples

```
Mark node "foo" as unschedulable
kubectl cordon foo
```

## Options

|                                                   |
|---------------------------------------------------|
| --dry-run string[="unchanged"]    Default: "none" |
|---------------------------------------------------|

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                       |
|-----------------------|
| -l, --selector string |
|-----------------------|

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|             |
|-------------|
| --as string |
|-------------|

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
|--------------------------------------------------------------------------------------------------------------|

|                    |
|--------------------|
| --as-group strings |
|--------------------|

|                                                                                               |
|-----------------------------------------------------------------------------------------------|
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups. |
|-----------------------------------------------------------------------------------------------|

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--as-uid string</code>                                                                                                                                    |
| UID to impersonate for the operation.                                                                                                                           |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache"                                                                                                   |
| Default cache directory                                                                                                                                         |
| <code>--certificate-authority string</code>                                                                                                                     |
| Path to a cert file for the certificate authority                                                                                                               |
| <code>--client-certificate string</code>                                                                                                                        |
| Path to a client certificate file for TLS                                                                                                                       |

| The name of the kubeconfig cluster to use                                                                                                                       |
| <code>--context string</code>                                                                                                                                   |
| The name of the kubeconfig context to use                                                                                                                       |
| <code>--default-not-ready-toleration-seconds int</code> Default: 300                                                                                            |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| <code>--default-unreachable-toleration-seconds int</code> Default: 300                                                                                          |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| <code>--disable-compression</code>                                                                                                                              |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| <code>--insecure-skip-tls-verify</code>                                                                                                                         |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl cp

## Synopsis

Copy files and directories to and from containers.

```
kubectl cp <file-spec-src> <file-spec-dest>
```

## Examples

```
!!!Important Note!!!
Requires that the 'tar' binary is present in your container
image. If 'tar' is not present, 'kubectl cp' will fail.
#
For advanced use cases, such as symlinks, wildcard expansion or
file mode preservation, consider using 'kubectl exec'.

Copy /tmp/foo local file to /tmp/bar in a remote pod in namespace <some-namespace>
tar cf - /tmp/foo | kubectl exec -i -n <some-namespace> <some-pod> -- tar xf - -C /tmp/bar

Copy /tmp/foo from a remote pod to /tmp/bar locally
kubectl exec -n <some-namespace> <some-pod> -- tar cf - /tmp/foo | tar xf - -C /tmp/bar

Copy /tmp/foo_dir local directory to /tmp/bar_dir in a remote pod in the default namespace
kubectl cp /tmp/foo_dir <some-pod>:/tmp/bar_dir

Copy /tmp/foo local file to /tmp/bar in a remote pod in a specific container
kubectl cp /tmp/foo <some-pod>:/tmp/bar -c <specific-container>

Copy /tmp/foo local file to /tmp/bar in a remote pod in namespace <some-namespace>
kubectl cp /tmp/foo <some-namespace>:<some-pod>:/tmp/bar

Copy /tmp/foo from a remote pod to /tmp/bar locally
kubectl cp <some-namespace>:<some-pod>:/tmp/foo /tmp/bar
```

## Options

|                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c, --container string                                                                                                                                                             |
| Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen |
| -h, --help                                                                                                                                                                         |
| help for cp                                                                                                                                                                        |
| --no-preserve                                                                                                                                                                      |
| The copied file/directory's ownership and permissions will not be preserved in the container                                                                                       |

|                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --retries int                                                                                                                                                       |
| Set number of retries to complete a copy operation from a container. Specify 0 to disable or any negative value for infinite retrying. The default is 0 (no retry). |
| --as string                                                                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                        |
| --as-group strings                                                                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                       |
| --as-uid string                                                                                                                                                     |
| UID to impersonate for the operation.                                                                                                                               |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                                  |
| Default cache directory                                                                                                                                             |
| --certificate-authority string                                                                                                                                      |
| Path to a cert file for the certificate authority                                                                                                                   |
| --client-certificate string                                                                                                                                         |
| Path to a client certificate file for TLS                                                                                                                           |
| --client-key string                                                                                                                                                 |
| Path to a client key file for TLS                                                                                                                                   |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                                   |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                                |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                                  |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                                |
| --cluster string                                                                                                                                                    |
| The name of the kubeconfig cluster to use                                                                                                                           |
| --context string                                                                                                                                                    |
| The name of the kubeconfig context to use                                                                                                                           |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                                                        |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                                                      |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string    Default: "none"                                                                                                                                                               |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| The address and port of the Kubernetes API server                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>--version, --version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
|----------------------------------------------------------------------------------------------------------------------------------------|

|                                   |
|-----------------------------------|
| <code>--warnings-as-errors</code> |
|-----------------------------------|

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl create

## Synopsis

Create a resource from a file or from stdin.

JSON and YAML formats are accepted.

```
kubectl create -f FILENAME
```

## Examples

```
Create a pod using the data in pod.json
kubectl create -f ./pod.json
```

```
Create a pod based on the JSON passed into stdin
cat pod.json | kubectl create -f -
```

```
Edit the data in registry.yaml in JSON then create the resource using the edited data
kubectl create -f registry.yaml --edit -o json
```

## Options

|                                                          |
|----------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true |
|----------------------------------------------------------|

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
|-------------------------------------------------------------------------------------------------------------------------------------------------|

|                                                             |
|-------------------------------------------------------------|
| <code>--dry-run string[="unchanged"]</code> Default: "none" |
|-------------------------------------------------------------|

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                     |
|---------------------|
| <code>--edit</code> |
|---------------------|

|                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Edit the API resource before creating                                                                                                                                                                               |
| --field-manager string    Default: "kubectl-create"                                                                                                                                                                 |
| Name of the manager used to track field ownership.                                                                                                                                                                  |
| -f, --filename strings                                                                                                                                                                                              |
| Filename, directory, or URL to files to use to create the resource                                                                                                                                                  |
| -h, --help                                                                                                                                                                                                          |
| help for create                                                                                                                                                                                                     |
| -k, --kustomize string                                                                                                                                                                                              |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                                |
| -o, --output string                                                                                                                                                                                                 |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                        |
| --raw string                                                                                                                                                                                                        |
| Raw URI to POST to the server. Uses the transport specified by the kubeconfig file.                                                                                                                                 |
| -R, --recursive                                                                                                                                                                                                     |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                     |
| --save-config                                                                                                                                                                                                       |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future. |
| -l, --selector string                                                                                                                                                                                               |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                          |
| --show-managed-fields                                                                                                                                                                                               |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                       |
| --template string                                                                                                                                                                                                   |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --windows-line-endings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Only relevant if --edit=true. Defaults to the line ending native to your platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                           |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |

# kubectl create clusterrole

## Synopsis

Create a cluster role.

```
kubectl create clusterrole NAME --verb=verb --resource=resource.group [--resource-
name=resourcename] [--dry-run=server|client|none]
```

## Examples

```
Create a cluster role named "pod-reader" that allows user to perform "get", "watch" and "list"
on pods
kubectl create clusterrole pod-reader --verb=get,list,watch --resource=pods

Create a cluster role named "pod-reader" with ResourceName specified
kubectl create clusterrole pod-reader --verb=get --resource=pods --resource-
name=readablepod --resource-name=anotherpod

Create a cluster role named "foo" with API Group specified
kubectl create clusterrole foo --verb=get,list,watch --resource=rs.apps

Create a cluster role named "foo" with SubResource specified
kubectl create clusterrole foo --verb=get,list,watch --resource=pods,pods/status

Create a cluster role name "foo" with NonResourceURL specified
kubectl create clusterrole "foo" --verb=get --non-resource-url=/logs/*

Create a cluster role name "monitoring" with AggregationRule specified
kubectl create clusterrole monitoring --aggregation-rule="rbac.example.com/aggregate-to-
monitoring=true"
```

## Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --aggregation-rule <comma-separated 'key=value' pairs>                                                                                                                                                   |
| An aggregation label selector for combining ClusterRoles.                                                                                                                                                |
| --allow-missing-template-keys    Default: true                                                                                                                                                           |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                         |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-create"                                                                                                                                                      |
| Name of the manager used to track field ownership.                                                                                                                                                       |
| -h, --help                                                                                                                                                                                               |
| help for clusterrole                                                                                                                                                                                     |

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |

| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create clusterrolebinding

## Synopsis

Create a cluster role binding for a particular cluster role.

```
kubectl create clusterrolebinding NAME --clusterrole=NAME [--user=username] [--group=groupname] [--serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none]
```

## Examples

```
Create a cluster role binding for user1, user2, and group1 using the cluster-admin cluster role
kubectl create clusterrolebinding cluster-admin --clusterrole=cluster-admin --user=user1 --user=user2 --group=group1
```

## Options

|                                                                                                                                                                                                          |                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyang and jsonpath output formats.                                                          |                           |
| --clusterrole string                                                                                                                                                                                     |                           |
| ClusterRole this ClusterRoleBinding should reference                                                                                                                                                     |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                           |
| --field-manager string                                                                                                                                                                                   | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                       |                           |
| --group strings                                                                                                                                                                                          |                           |
| Groups to bind to the clusterrole. The flag can be repeated to add multiple groups.                                                                                                                      |                           |

| Username to bind to the clusterrole. The flag can be repeated to add multiple users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>--validate string[="strict"]</code> Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |

|                                                                                                              |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |

# kubect create configmap

## Synopsis

Create a config map based on a file, directory, or specified literal value.

A single config map may package one or more key/value pairs.

When creating a config map based on a file, the key will default to the basename of the file, and the value will default to the file content. If the basename is an invalid key, you may specify an alternate key.

When creating a config map based on a directory, each file whose basename is a valid key in the directory will be packaged into the config map. Any directory entries except regular files are ignored (e.g. subdirectories, symlinks, devices, pipes, etc).

```
kubectl create configmap NAME [--from-file=[key=]source] [--from-literal=key1=value1] [--dry-run=server|client|none]
```

## Examples

```
Create a new config map named my-config based on folder bar
kubectl create configmap my-config --from-file=path/to/bar

Create a new config map named my-config with specified keys instead of file basenames on disk
kubectl create configmap my-config --from-file=key1=/path/to/bar/file1.txt --from-file=key2=/path/to/bar/file2.txt

Create a new config map named my-config with key1=config1 and key2=config2
kubectl create configmap my-config --from-literal=key1=config1 --from-literal=key2=config2

Create a new config map named my-config from the key=value pairs in the file
kubectl create configmap my-config --from-file=path/to/bar

Create a new config map named my-config from an env file
kubectl create configmap my-config --from-env-file=path/to/foo.env --from-env-file=path/to/bar.env
```

## Options

|                                                                                                                                                                                                          |                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |                           |
| --append-hash                                                                                                                                                                                            |                           |
| Append a hash of the configmap to its name.                                                                                                                                                              |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                           |
| --field-manager string                                                                                                                                                                                   | Default: "kubectl-create" |

|                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of the manager used to track field ownership.                                                                                                                                                                                                                                                        |
| --from-env-file strings                                                                                                                                                                                                                                                                                   |
| Specify the path to a file to read lines of key=val pairs to create a configmap.                                                                                                                                                                                                                          |
| --from-file strings                                                                                                                                                                                                                                                                                       |
| Key file can be specified using its file path, in which case file basename will be used as configmap key, or optionally with a key and file path, in which case the given key will be used. Specifying a directory will iterate each named file in the directory whose basename is a valid configmap key. |
| --from-literal strings                                                                                                                                                                                                                                                                                    |
| Specify a key and literal value to insert in configmap (i.e. mykey=somevalue)                                                                                                                                                                                                                             |

| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                                                                              |
| --save-config                                                                                                                                                                                                                                                                                             |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                                                                       |
| --show-managed-fields                                                                                                                                                                                                                                                                                     |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                 |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                         |

Must be one of: strict (or true), warn, ignore (or false).  
 "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.  
 "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.  
 "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create cronjob

## Synopsis

Create a cron job with the specified name.

```
kubectl create cronjob NAME --image=image --schedule='0/5 * * * ?' -- [COMMAND] [args...]
[flags]
```

## Examples

```
Create a cron job
kubectl create cronjob my-job --image=busybox --schedule="*/1 * * * *"

Create a cron job with a command
kubectl create cronjob my-job --image=busybox --schedule="*/1 * * * *" -- date
```

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                                               |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <p>Must be one of: strict (or true), warn, ignore (or false).</p> <p>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.</p> <p>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.</p> <p>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.</p> |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                 |
| --as-group strings                                                                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                |

| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create deployment

## Synopsis

Create a deployment with the specified name.

```
kubectl create deployment NAME --image=image -- [COMMAND] [args...]
```

## Examples

```
Create a deployment named my-dep that runs the busybox image
kubectl create deployment my-dep --image=busybox

Create a deployment with a command
kubectl create deployment my-dep --image=busybox -- date

Create a deployment named my-dep that runs the nginx image with 3 replicas
kubectl create deployment my-dep --image=nginx --replicas=3

Create a deployment named my-dep that runs the busybox image and expose port 5701
kubectl create deployment my-dep --image=busybox --port=5701

Create a deployment named my-dep that runs multiple containers
kubectl create deployment my-dep --image=busybox:latest --image=ubuntu:latest --
image=nginx
```

## Options

|                                                                                                                                                                                                          |                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                         |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                           |

| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# kubectl create ingress

## Synopsis

Create an ingress with the specified name.

```
kubectl create ingress NAME --rule=host/path=service:port[,tls[=secret]]
```

## Examples

```
Create a single ingress called 'simple' that directs requests to foo.com/bar to svc
svc1:8080 with a TLS secret "my-cert"
kubectl create ingress simple --rule="foo.com/bar=svc1:8080,tls=my-cert"
```

```
Create a catch all ingress of "/"path" pointing to service svc:port and Ingress Class as
"otheringress"
kubectl create ingress catch-all --class=otheringress --rule="/path=svc:port"
```

```
Create an ingress with two annotations: ingress.annotation1 and ingress.annotations2
kubectl create ingress annotated --class=default --rule="foo.com/bar=svc:port" \
--annotation ingress.annotation1=foo \
--annotation ingress.annotation2=bla
```

```
Create an ingress with the same host and multiple paths
kubectl create ingress multipath --class=default \
--rule="foo.com/=svc:port" \
--rule="foo.com/admin/=svcadmin:portadmin"
```

```
Create an ingress with multiple hosts and the pathType as Prefix
kubectl create ingress ingress1 --class=default \
--rule="foo.com/path*=svc:8080" \
--rule="bar.com/admin*=svc2:http"
```

```
Create an ingress with TLS enabled using the default ingress certificate and different path
types
kubectl create ingress ingtls --class=default \
--rule="foo.com/=svc:https,tls" \
--rule="foo.com/path/subpath*=othersvc:8080"
```

```
Create an ingress with TLS enabled using a specific secret and pathType as Prefix
kubectl create ingress ingsecret --class=default \
--rule="foo.com/*=svc:8080,tls=secret1"
```

```
Create an ingress with a default backend
kubectl create ingress ingdefault --class=default \
--default-backend=defaultsvc:http \
--rule="foo.com/*=svc:8080,tls=secret1"
```

# Options

|                                                                                                                                                                                                                     |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                                       | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                                    |                           |
| --annotation strings                                                                                                                                                                                                |                           |
| Annotation to insert in the ingress object, in the format annotation=value                                                                                                                                          |                           |
| --class string                                                                                                                                                                                                      |                           |
| Ingress Class to be used                                                                                                                                                                                            |                           |
| --default-backend string                                                                                                                                                                                            |                           |
| Default service for backend, in format of svcname:port                                                                                                                                                              |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                                      | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.            |                           |
| --field-manager string                                                                                                                                                                                              | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                                  |                           |
| -h, --help                                                                                                                                                                                                          |                           |
| help for ingress                                                                                                                                                                                                    |                           |
| -o, --output string                                                                                                                                                                                                 |                           |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                        |                           |
| --rule strings                                                                                                                                                                                                      |                           |
| Rule in format host/path=service:port[,tls=secretname]. Paths containing the leading character '*' are considered pathType=Prefix. tls argument is optional.                                                        |                           |
| --save-config                                                                                                                                                                                                       |                           |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future. |                           |
| --show-managed-fields                                                                                                                                                                                               |                           |

|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --template string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                           |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |

| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                                                                                                                                                                                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| Bearer token for authentication to the API server                                                            |
| --user string                                                                                                |
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create job

## Synopsis

Create a job with the specified name.

```
kubectl create job NAME --image=image [--from=cronjob/name] -- [COMMAND] [args...]
```

## Examples

```
Create a job
kubectl create job my-job --image=busybox

Create a job with a command
kubectl create job my-job --image=busybox -- date

Create a job from a cron job named "a-cronjob"
kubectl create job test-job --from=cronjob/a-cronjob
```

## Options

|                               |               |
|-------------------------------|---------------|
| --allow-missing-template-keys | Default: true |
|-------------------------------|---------------|

|                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                                                                                                |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                                                                                                                                              |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                                                                                       |
| --field-manager string    Default: "kubectl-create"                                                                                                                                                                                                                                                                            |
| Name of the manager used to track field ownership.                                                                                                                                                                                                                                                                             |
| --from string                                                                                                                                                                                                                                                                                                                  |
| The name of the resource to create a Job from (only cronjob is supported).                                                                                                                                                                                                                                                     |
| -h, --help                                                                                                                                                                                                                                                                                                                     |

| Image name to run.                                                                                                                                                                                                                                                                                                             |
| -o, --output string                                                                                                                                                                                                                                                                                                            |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                                                                                                   |
| --save-config                                                                                                                                                                                                                                                                                                                  |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                                                                                            |
| --show-managed-fields                                                                                                                                                                                                                                                                                                          |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                                                                  |
| --template string                                                                                                                                                                                                                                                                                                              |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                       |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                              |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not. |

"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.  
"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                               |
| --cluster string                                                                                                   |
| The name of the kubeconfig cluster to use                                                                          |
| --context string                                                                                                   |
| The name of the kubeconfig context to use                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                                                        |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                                                      |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                                                                                                                                                                             |
| If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                                                                                                                                                                        |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string    Default: "none"                                                                                                                                                               |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| The address and port of the Kubernetes API server                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |

|                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>--version, --version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
|----------------------------------------------------------------------------------------------------------------------------------------|

|                                   |
|-----------------------------------|
| <code>--warnings-as-errors</code> |
|-----------------------------------|

|                                                                                      |
|--------------------------------------------------------------------------------------|
| Treat warnings received from the server as errors and exit with a non-zero exit code |
|--------------------------------------------------------------------------------------|

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create namespace

## Synopsis

Create a namespace with the specified name.

```
kubectl create namespace NAME [--dry-run=server|client|none]
```

## Examples

```
Create a new namespace named my-namespace
kubectl create namespace my-namespace
```

## Options

|                                                          |
|----------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true |
|----------------------------------------------------------|

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
|-------------------------------------------------------------------------------------------------------------------------------------------------|

|                                                             |
|-------------------------------------------------------------|
| <code>--dry-run string[="unchanged"]</code> Default: "none" |
|-------------------------------------------------------------|

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                                                               |
|---------------------------------------------------------------|
| <code>--field-manager string</code> Default: "kubectl-create" |
|---------------------------------------------------------------|

|                                                    |
|----------------------------------------------------|
| Name of the manager used to track field ownership. |
|----------------------------------------------------|

|                         |
|-------------------------|
| <code>-h, --help</code> |

|                                  |
|----------------------------------|
| <code>-o, --output string</code> |
|----------------------------------|

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| --save-config                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --show-managed-fields                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --template string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                            |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Path to a client key file for TLS                                                                                                                               |
| <code>--cloud-provider-gce-l7lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,35.191.0.0/16                                                                    |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| <code>--cloud-provider-gce-lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                      |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| <code>--cluster string</code>                                                                                                                                   |
| The name of the kubeconfig cluster to use                                                                                                                       |
| <code>--context string</code>                                                                                                                                   |
| The name of the kubeconfig context to use                                                                                                                       |
| <code>--default-not-ready-toleration-seconds int</code> Default: 300                                                                                            |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| <code>--default-unreachable-toleration-seconds int</code> Default: 300                                                                                          |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| <code>--disable-compression</code>                                                                                                                              |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| <code>--insecure-skip-tls-verify</code>                                                                                                                         |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| <code>--kubeconfig string</code>                                                                                                                                |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| <code>--match-server-version</code>                                                                                                                             |
| Require server version to match client version                                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl create poddisruptionbudget

## Synopsis

Create a pod disruption budget with the specified name, selector, and desired minimum available pods.

```
kubectl create poddisruptionbudget NAME --selector=SELECTOR --min-available=N [--dry-run=server|client|none]
```

## Examples

```
Create a pod disruption budget named my-pdb that will select all pods with the app=rails label
and require at least one of them being available at any point in time
```

```
kubectl create poddisruptionbudget my-pdb --selector=app=rails --min-available=1

Create a pod disruption budget named my-pdb that will select all pods with the app=nginx
label
and require at least half of the pods selected to be available at any point in time
kubectl create pdb my-pdb --selector=app=nginx --min-available=50%
```

## Options

|                                                                                                                                                                                                                     |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                                       | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                                     |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                                      | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.            |                           |
| --field-manager string                                                                                                                                                                                              | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                                  |                           |
| -h, --help                                                                                                                                                                                                          |                           |
| help for poddisruptionbudget                                                                                                                                                                                        |                           |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                                              |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <p>Must be one of: strict (or true), warn, ignore (or false).</p> <p>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.</p> <p>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.</p> <p>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.</p> |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Password for basic authentication to the API server</p>                                                                                                                                               |
| <p>--profile string   Default: "none"</p>                                                                                                                                                                |
| <p>Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)</p>                                                                                                             |
| <p>--profile-output string   Default: "profile.pprof"</p>                                                                                                                                                |
| <p>Name of the file to write the profile to</p>                                                                                                                                                          |
| <p>--request-timeout string   Default: "0"</p>                                                                                                                                                           |
| <p>The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.</p> |
| <p>-s, --server string</p>                                                                                                                                                                               |
| <p>The address and port of the Kubernetes API server</p>                                                                                                                                                 |
| <p>--storage-driver-buffer-duration duration   Default: 1m0s</p>                                                                                                                                         |
| <p>Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction</p>                                                                 |
| <p>--storage-driver-db string   Default: "cadvisor"</p>                                                                                                                                                  |
| <p>database name</p>                                                                                                                                                                                     |
| <p>--storage-driver-host string   Default: "localhost:8086"</p>                                                                                                                                          |
| <p>database host:port</p>                                                                                                                                                                                |

# kubectrl create priorityclass

## Synopsis

Create a priority class with the specified name, value, globalDefault and description.

```
kubectrl create priorityclass NAME --value=VALUE --global-default=BOOL [--dry-run=server|client|none]
```

## Examples

```
Create a priority class named high-priority
kubectrl create priorityclass high-priority --value=1000 --description="high priority"

Create a priority class named default-priority that is considered as the global default priority
kubectrl create priorityclass default-priority --value=1000 --global-default=true --description="default priority"

Create a priority class named high-priority that cannot preempt pods with lower priority
```

```
kubectcl create priorityclass high-priority --value=1000 --description="high priority" --preemption-policy="Never"
```

## Options

|                                                                                                                                                                                                                      |                                 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|
| --allow-missing-template-keys                                                                                                                                                                                        | Default: true                   |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                                      |                                 |
| --description string                                                                                                                                                                                                 |                                 |
| description is an arbitrary string that usually provides guidelines on when this priority class should be used.                                                                                                      |                                 |
| --dry-run string[="unchanged"]                                                                                                                                                                                       | Default: "none"                 |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.             |                                 |
| --field-manager string                                                                                                                                                                                               | Default: "kubectcl-create"      |
| Name of the manager used to track field ownership.                                                                                                                                                                   |                                 |
| --global-default                                                                                                                                                                                                     |                                 |
| global-default specifies whether this PriorityClass should be considered as the default priority.                                                                                                                    |                                 |
| -h, --help                                                                                                                                                                                                           |                                 |
| help for priorityclass                                                                                                                                                                                               |                                 |
| -o, --output string                                                                                                                                                                                                  |                                 |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                         |                                 |
| --preemption-policy string                                                                                                                                                                                           | Default: "PreemptLowerPriority" |
| preemption-policy is the policy for preempting pods with lower priority.                                                                                                                                             |                                 |
| --save-config                                                                                                                                                                                                        |                                 |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectcl apply on this object in the future. |                                 |
| --show-managed-fields                                                                                                                                                                                                |                                 |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --value int32                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| the value of this priority class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                                                                                              |

# kubectrl create quota

## Synopsis

Create a resource quota with the specified name, hard limits, and optional scopes.

```
kubectrl create quota NAME [--hard=key1=value1,key2=value2] [--scopes=Scope1,Scope2] [--dry-run=server|client|none]
```

## Examples

```
Create a new resource quota named my-quota
kubectrl create quota my-quota --
hard=cpu=1,memory=1G,pods=2,services=3,replicationcontrollers=2,resourcequotas=1,secrets=
5,persistentvolumeclaims=10
```

```
Create a new resource quota named best-effort
kubectrl create quota best-effort --hard=pods=100 --scopes=BestEffort
```

|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                                                                            | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                          |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                                                                           | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                 |                           |
| --field-manager string                                                                                                                                                                                                                                   | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                                                                       |                           |
| --hard string                                                                                                                                                                                                                                            |                           |
| A comma-delimited set of resource=quantity pairs that define a hard limit.                                                                                                                                                                               |                           |

| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |                           |
| --save-config                                                                                                                                                                                                                                            |                           |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                      |                           |
| --scopes string                                                                                                                                                                                                                                          |                           |
| A comma-delimited set of quota scopes that must all match each object tracked by the quota.                                                                                                                                                              |                           |
| --show-managed-fields                                                                                                                                                                                                                                    |                           |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |                           |
| --template string                                                                                                                                                                                                                                        |                           |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |                           |
| --validate string[="strict"]                                                                                                                                                                                                                             | Default: "strict"         |

Must be one of: strict (or true), warn, ignore (or false).  
 "true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.  
 "warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.  
 "false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |

| Bearer token for authentication to the API server                                                                                                                                                 |
| <code>--user string</code>                                                                                                                                                                        |
| The name of the kubeconfig user to use                                                                                                                                                            |
| <code>--username string</code>                                                                                                                                                                    |

|                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username for basic authentication to the API server                                                                                                  |
| <code>--version version[=true]</code>                                                                                                                |
| <code>--version</code> , <code>--version=raw</code> prints version information and quits; <code>--version=vX.Y.Z...</code> sets the reported version |
| <code>--warnings-as-errors</code>                                                                                                                    |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                                                 |

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create role

## Synopsis

Create a role with single rule.

```
kubectl create role NAME --verb=verb --resource=resource.group/subresource [--resource-name=resourcename] [--dry-run=server|client|none]
```

## Examples

```
Create a role named "pod-reader" that allows user to perform "get", "watch" and "list" on pods
kubectl create role pod-reader --verb=get --verb=list --verb=watch --resource=pods

Create a role named "pod-reader" with ResourceName specified
kubectl create role pod-reader --verb=get --resource=pods --resource-name=readablepod --resource-name=anotherpod

Create a role named "foo" with API Group specified
kubectl create role foo --verb=get,list,watch --resource=rs.apps

Create a role named "foo" with SubResource specified
kubectl create role foo --verb=get,list,watch --resource=pods,pods/status
```

## Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-missing-template-keys</code> Default: true                                                                                        |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |

|                                                                                                                                                                                                                                                           |                           |

|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --verb strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | --request-timeout string    Default: "0"                                                                                                                                                          |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | -s, --server string                                                                                                                                                                               |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
|  | database name                                                                                                                                                                                     |
|  | --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
|  | database host:port                                                                                                                                                                                |
|  | --storage-driver-password string    Default: "root"                                                                                                                                               |
|  | database password                                                                                                                                                                                 |
|  | --storage-driver-secure                                                                                                                                                                           |
|  | use secure connection with database                                                                                                                                                               |
|  | --storage-driver-table string    Default: "stats"                                                                                                                                                 |
|  | table name                                                                                                                                                                                        |
|  | --storage-driver-user string    Default: "root"                                                                                                                                                   |
|  | database username                                                                                                                                                                                 |
|  | --tls-server-name string                                                                                                                                                                          |
|  | Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
|  | --token string                                                                                                                                                                                    |
|  | Bearer token for authentication to the API server                                                                                                                                                 |
|  | --user string                                                                                                                                                                                     |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create rolebinding

## Synopsis

Create a role binding for a particular role or cluster role.

```
kubectl create rolebinding NAME --clusterrole=NAME|--role=NAME [--user=username] [--group=groupname] [--serviceaccount=namespace:serviceaccountname] [--dry-run=server|client|none]
```

## Examples

```
Create a role binding for user1, user2, and group1 using the admin cluster role
kubectl create rolebinding admin --clusterrole=admin --user=user1 --user=user2 --group=group1
```

```
Create a role binding for serviceaccount monitoring:sa-dev using the admin role
kubectl create rolebinding admin-binding --role=admin --serviceaccount=monitoring:sa-dev
```

## Options

|                                                                                                                                                 |

| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create secret

## Synopsis

Create a secret with specified type.

A docker-registry type secret is for accessing a container registry.

A generic type secret indicate an Opaque secret type.

A tls type secret holds TLS certificate and its associated key.

kubectl create secret (docker-registry | generic | tls)

## Options

|                 |
|-----------------|
| -h, --help      |
| help for secret |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                                                             |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl create secret docker-registry

## Synopsis

Create a new secret for use with Docker registries.

Dockercfg secrets are used to authenticate against Docker registries.

When using the Docker command line to push images, you can authenticate to a given registry by running:

```
'$ docker login DOCKER_REGISTRY_SERVER --username=DOCKER_USER --password=DOCKER_PASSWORD --email=DOCKER_EMAIL'.
```

That produces a ~/.dockercfg file that is used by subsequent 'docker push' and 'docker pull' commands to authenticate to the registry. The email address is optional.

When creating applications, you may have a Docker registry that requires authentication. In order for the nodes to pull images on your behalf, they must have the credentials. You can provide this information by creating a dockercfg secret and attaching it to your service account.

```
kubectl create secret docker-registry NAME --docker-username=user --docker-password=password --docker-email=email [--docker-server=string] [--from-file=[key=]source] [--dry-run=server|client|none]
```

## Examples

```
If you do not already have a .dockercfg file, create a dockercfg secret directly
kubectl create secret docker-registry my-secret --docker-server=DOCKER_REGISTRY_SERVER --docker-username=DOCKER_USER --docker-password=DOCKER_PASSWORD --docker-email=DOCKER_EMAIL

Create a new secret named my-secret from ~/.docker/config.json
kubectl create secret docker-registry my-secret --from-file=.dockerconfigjson=path/to/.docker/config.json
```

## Options

|                                                                                                                                                  |               |
|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| <code>--allow-missing-template-keys</code>                                                                                                       | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats. |               |
| <code>--append-hash</code>                                                                                                                       |               |
| Append a hash of the secret to its name.                                                                                                         |               |
| <code>--docker-email</code>                                                                                                                      | string        |

|                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Email for Docker registry                                                                                                                                                                                                                                                                  |
| --docker-password string                                                                                                                                                                                                                                                                   |
| Password for Docker registry authentication                                                                                                                                                                                                                                                |
| --docker-server string   Default: "https://index.docker.io/v1/"                                                                                                                                                                                                                            |

| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                                                               |
| --save-config                                                                                                                                                                                                                                                                              |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future.                                                                        |
| --show-managed-fields                                                                                                                                                                                                                                                                      |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                                                              |
| --template string                                                                                                                                                                                                                                                                          |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                           |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                           |                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                  | Default: "0"                                                                                                                                                                                      |
|                                           | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                       |                                                                                                                                                                                                   |
|                                           | The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration | Default: 1m0s                                                                                                                                                                                     |
|                                           | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string                | Default: "cadvisor"                                                                                                                                                                               |

# kubectl create secret generic

## Synopsis

Create a secret based on a file, directory, or specified literal value.

A single secret may package one or more key/value pairs.

When creating a secret based on a file, the key will default to the basename of the file, and the value will default to the file content. If the basename is an invalid key or you wish to chose your own, you may specify an alternate key.

When creating a secret based on a directory, each file whose basename is a valid key in the directory will be packaged into the secret. Any directory entries except regular files are ignored (e.g. subdirectories, symlinks, devices, pipes, etc).

```
kubectl create secret generic NAME [--type=string] [--from-file=[key=]source] [--from-literal=key1=value1] [--dry-run=server|client|none]
```

## Examples

```
Create a new secret named my-secret with keys for each file in folder bar
kubectl create secret generic my-secret --from-file=path/to/bar

Create a new secret named my-secret with specified keys instead of names on disk
kubectl create secret generic my-secret --from-file=ssh-privatekey=path/to/id_rsa --from-file=ssh-publickey=path/to/id_rsa.pub

Create a new secret named my-secret with key1=supersecret and key2=topsecret
```

```
kubectl create secret generic my-secret --from-literal=key1=supersecret --from-literal=key2=topsecret

Create a new secret named my-secret using a combination of a file and a literal
kubectl create secret generic my-secret --from-file=ssh-privatekey=path/to/id_rsa --from-literal=passphrase=topsecret

Create a new secret named my-secret from env files
kubectl create secret generic my-secret --from-env-file=path/to/foo.env --from-env-file=path/to/bar.env
```

## Options

|                                                                                                                                                                                                                                                                                            |                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| <code>--allow-missing-template-keys</code>                                                                                                                                                                                                                                                 | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                                                                                                            |                           |
| <code>--append-hash</code>                                                                                                                                                                                                                                                                 |                           |
| Append a hash of the secret to its name.                                                                                                                                                                                                                                                   |                           |
| <code>--dry-run string[="unchanged"]</code>                                                                                                                                                                                                                                                | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.                                                                                   |                           |
| <code>--field-manager string</code>                                                                                                                                                                                                                                                        | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                                                                                                         |                           |
| <code>--from-env-file strings</code>                                                                                                                                                                                                                                                       |                           |
| Specify the path to a file to read lines of key=val pairs to create a secret.                                                                                                                                                                                                              |                           |
| <code>--from-file strings</code>                                                                                                                                                                                                                                                           |                           |
| Key files can be specified using their file path, in which case a default name will be given to them, or optionally with a name and file path, in which case the given name will be used. Specifying a directory will iterate each named file in the directory that is a valid secret key. |                           |
| <code>--from-literal strings</code>                                                                                                                                                                                                                                                        |                           |
| Specify a key and literal value to insert in secret (i.e. mykey=somevalue)                                                                                                                                                                                                                 |                           |

| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl create secret](#) - Create a secret using a specified subcommand

# kubectl create secret tls

## Synopsis

Create a TLS secret from the given public/private key pair.

The public/private key pair must exist beforehand. The public key certificate must be .PEM encoded and match the given private key.

```
kubectl create secret tls NAME --cert=path/to/cert/file --key=path/to/key/file [--dry-run=server|client|none]
```

## Examples

```
Create a new TLS secret named tls-secret with the given key pair
kubectl create secret tls tls-secret --cert=path/to/tls.crt --key=path/to/tls.key
```

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                                                                                 |
| table name                                                                                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                                                                                   |
| database username                                                                                                                                                                                 |
| --tls-server-name string                                                                                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                                                                                                                                                                                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| Bearer token for authentication to the API server                                                            |
| --user string                                                                                                |
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--as-uid string</code>                                                                                                                                    |
| UID to impersonate for the operation.                                                                                                                           |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache"                                                                                                   |
| Default cache directory                                                                                                                                         |
| <code>--certificate-authority string</code>                                                                                                                     |
| Path to a cert file for the certificate authority                                                                                                               |
| <code>--client-certificate string</code>                                                                                                                        |
| Path to a client certificate file for TLS                                                                                                                       |
| <code>--client-key string</code>                                                                                                                                |
| Path to a client key file for TLS                                                                                                                               |
| <code>--cloud-provider-gce-l7lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,35.191.0.0/16                                                                    |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| <code>--cloud-provider-gce-lb-src-cidrs cidrs</code> Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                   |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| <code>--cluster string</code>                                                                                                                                   |
| The name of the kubeconfig cluster to use                                                                                                                       |
| <code>--context string</code>                                                                                                                                   |
| The name of the kubeconfig context to use                                                                                                                       |
| <code>--default-not-ready-toleration-seconds int</code> Default: 300                                                                                            |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| <code>--default-unreachable-toleration-seconds int</code> Default: 300                                                                                          |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| <code>--disable-compression</code>                                                                                                                              |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| <code>--insecure-skip-tls-verify</code>                                                                                                                         |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |

# kubectl create service clusterip

## Synopsis

Create a ClusterIP service with the specified name.

```
kubectl create service clusterip NAME [--tcp=<port>:<targetPort>] [--dry-run=server|client|none]
```

## Examples

```
Create a new ClusterIP service named my-cs
kubectl create service clusterip my-cs --tcp=5678:8080

Create a new ClusterIP service named my-cs (in headless mode)
kubectl create service clusterip my-cs --clusterip="None"
```

## Options

|                                                                                                                                                                                                          |                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                            | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats.                                                         |                           |
| --clusterip string                                                                                                                                                                                       |                           |
| Assign your own ClusterIP or set to 'None' for a 'headless' service (no loadbalancing).                                                                                                                  |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                           | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                           |
| --field-manager string                                                                                                                                                                                   | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                       |                           |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |

| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl create service](#) - Create a service using a specified subcommand

# kubectl create service externalname

## Synopsis

Create an ExternalName service with the specified name.

ExternalName service references to an external DNS address instead of only pods, which will allow application authors to reference services that exist off platform, on other clusters, or locally.

```
kubectl create service externalname NAME --external-name external.name [--dry-run=server|client|none]
```

## Examples

```
Create a new ExternalName service named my-ns
kubectl create service externalname my-ns --external-name bar.com
```

## Options

|                                                                                                                                                                                                                     |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                                       | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                                     |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                                      | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.            |                           |
| --external-name string                                                                                                                                                                                              |                           |
| External name of service                                                                                                                                                                                            |                           |
| --field-manager string                                                                                                                                                                                              | Default: "kubectl-create" |
| Name of the manager used to track field ownership.                                                                                                                                                                  |                           |
| -h, --help                                                                                                                                                                                                          |                           |
| help for externalname                                                                                                                                                                                               |                           |
| -o, --output string                                                                                                                                                                                                 |                           |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                        |                           |
| --save-config                                                                                                                                                                                                       |                           |
| If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future. |                           |
| --show-managed-fields                                                                                                                                                                                               |                           |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                       |                           |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                           |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

- [kubectl create service](#) - Create a service using a specified subcommand

# kubectl create service loadbalancer

## Synopsis

Create a LoadBalancer service with the specified name.

```
kubectl create service loadbalancer NAME [--tcp=port:targetPort] [--dry-run=server|client|none]
```

## Examples

```
Create a new LoadBalancer service named my-lbs
kubectl create service loadbalancer my-lbs --tcp=5678:8080
```

## Options

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-missing-template-keys    Default: true                                                                                                                                                           |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |
| --dry-run string[="unchanged"]    Default: "none"                                                                                                                                                        |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                           |

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                                               |                           |
| --validate string[="strict"]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Default: "strict"         |
| <p>Must be one of: strict (or true), warn, ignore (or false).</p> <p>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.</p> <p>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.</p> <p>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields.</p> |                           |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                           |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                           |

| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                       |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                     |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | If true, opt-out of response compression for all requests to the server                                                                                                                           |
|  | <code>--insecure-skip-tls-verify</code>                                                                                                                                                           |
|  | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
|  | <code>--kubeconfig string</code>                                                                                                                                                                  |
|  | Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
|  | <code>--match-server-version</code>                                                                                                                                                               |
|  | Require server version to match client version                                                                                                                                                    |
|  | <code>-n, --namespace string</code>                                                                                                                                                               |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | <code>--password string</code>                                                                                                                                                                    |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | <code>--profile string</code> Default: "none"                                                                                                                                                     |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | <code>--profile-output string</code> Default: "profile.pprof"                                                                                                                                     |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | <code>--request-timeout string</code> Default: "0"                                                                                                                                                |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | <code>-s, --server string</code>                                                                                                                                                                  |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                                                                                              |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | <code>--storage-driver-db string</code> Default: "cadvisor"                                                                                                                                       |
|  | database name                                                                                                                                                                                     |
|  | <code>--storage-driver-host string</code> Default: "localhost:8086"                                                                                                                               |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database host:port                                                                                                           |
| --storage-driver-password string    Default: "root"                                                                          |
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl create service](#) - Create a service using a specified subcommand

# kubectl create service nodeport

## Synopsis

Create a NodePort service with the specified name.

```
kubectl create service nodeport NAME [--tcp=port:targetPort] [--dry-run=server|client|none]
```

## Examples

```
Create a new NodePort service named my-ns
kubectl create service nodeport my-ns --tcp=5678:8080
```

## Options

|                                                                                                                                                                                                                     |                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --allow-missing-template-keys                                                                                                                                                                                       | Default: true             |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyang and jsonpath output formats.                                                                     |                           |
| --dry-run string[="unchanged"]                                                                                                                                                                                      | Default: "none"           |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource.            |                           |

| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl create service](#) - Create a service using a specified subcommand

# kubectl create serviceaccount

## Synopsis

Create a service account with the specified name.

```
kubectl create serviceaccount NAME [--dry-run=server|client|none]
```

## Examples

```
Create a new service account named my-service-account
kubectl create serviceaccount my-service-account
```

| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].                                                                                                                                                                                                                                                                                                                                                                            |
| --validate string[="strict"]    Default: "strict"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Must be one of: strict (or true), warn, ignore (or false).<br>"true" or "strict" will use a schema to validate the input and fail the request if invalid. It will perform server side validation if ServerSideFieldValidation is enabled on the api-server, but will fall back to less reliable client-side validation if not.<br>"warn" will warn about unknown or duplicate fields without blocking the request if server-side field validation is enabled on the API server, and behave as "ignore" otherwise.<br>"false" or "ignore" will not perform any schema validation, silently dropping any unknown or duplicate fields. |
| --as string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                                                                                                                                                                               |
| Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                                                                                                                                                                            |
| Require server version to match client version                                                                                                                                                    |
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |

|                                                                                                                              |                           |
|------------------------------------------------------------------------------------------------------------------------------|---------------------------|
| --storage-driver-db string                                                                                                   | Default: "cadvisor"       |
| database name                                                                                                                |                           |
| --storage-driver-host string                                                                                                 | Default: "localhost:8086" |
| database host:port                                                                                                           |                           |
| --storage-driver-password string                                                                                             | Default: "root"           |
| database password                                                                                                            |                           |
| --storage-driver-secure                                                                                                      |                           |
| use secure connection with database                                                                                          |                           |
| --storage-driver-table string                                                                                                | Default: "stats"          |
| table name                                                                                                                   |                           |
| --storage-driver-user string                                                                                                 | Default: "root"           |
| database username                                                                                                            |                           |
| --tls-server-name string                                                                                                     |                           |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |                           |
| --token string                                                                                                               |                           |
| Bearer token for authentication to the API server                                                                            |                           |
| --user string                                                                                                                |                           |
| The name of the kubeconfig user to use                                                                                       |                           |
| --username string                                                                                                            |                           |
| Username for basic authentication to the API server                                                                          |                           |
| --version version[=true]                                                                                                     |                           |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |                           |
| --warnings-as-errors                                                                                                         |                           |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |                           |

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl create token

## Synopsis

Request a service account token.

```
kubectl create token SERVICE_ACCOUNT_NAME
```

## Examples

```
Request a token to authenticate to the kube-apiserver as the service account "myapp" in the
current namespace
kubectl create token myapp

Request a token for a service account in a custom namespace
kubectl create token myapp --namespace myns

Request a token with a custom expiration
kubectl create token myapp --duration 10m

Request a token with a custom audience
kubectl create token myapp --audience https://example.com

Request a token bound to an instance of a Secret object
kubectl create token myapp --bound-object-kind Secret --bound-object-name mysecret

Request a token bound to an instance of a Secret object with a specific UID
kubectl create token myapp --bound-object-kind Secret --bound-object-name mysecret --
bound-object-uid 0d4691ed-659b-4935-a832-355f77ee47cc
```

## Options

|                                                                                                                                                                                    |               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| --allow-missing-template-keys                                                                                                                                                      | Default: true |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                    |               |
| --audience strings                                                                                                                                                                 |               |
| Audience of the requested token. If unset, defaults to requesting a token for use with the Kubernetes API server. May be repeated to request a token valid for multiple audiences. |               |
| --bound-object-kind string                                                                                                                                                         |               |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kind of an object to bind the token to. Supported kinds are Pod, Secret. If set, --bound-object-name must be provided.                                                                                                                                    |
| --bound-object-name string                                                                                                                                                                                                                                |
| Name of an object to bind the token to. The token will expire when the object is deleted. Requires --bound-object-kind.                                                                                                                                   |
| --bound-object-uid string                                                                                                                                                                                                                                 |
| UID of an object to bind the token to. Requires --bound-object-kind and --bound-object-name. If unset, the UID of the existing object is used.                                                                                                            |
| --duration duration                                                                                                                                                                                                                                       |
| Requested lifetime of the issued token. If not set or if set to 0, the lifetime will be determined by the server automatically. The server may return a token with a longer or shorter lifetime.                                                          |
| -h, --help                                                                                                                                                                                                                                                |

|  | Password for basic authentication to the API server                                                                                                                                               |
|  | --profile string   Default: "none"                                                                                                                                                                |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | --profile-output string   Default: "profile.pprof"                                                                                                                                                |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | --request-timeout string   Default: "0"                                                                                                                                                           |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | -s, --server string                                                                                                                                                                               |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
|  | database name                                                                                                                                                                                     |
|  | --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
|  | database host:port                                                                                                                                                                                |
|  | --storage-driver-password string   Default: "root"                                                                                                                                                |
|  | database password                                                                                                                                                                                 |
|  | --storage-driver-secure                                                                                                                                                                           |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl create](#) - Create a resource from a file or from stdin

# kubectl debug

## Synopsis

Debug cluster resources using interactive debugging containers.

'debug' provides automation for common debugging tasks for cluster objects identified by resource and name. Pods will be used by default if no resource is specified.

The action taken by 'debug' varies depending on what resource is specified. Supported actions include:

- Workload: Create a copy of an existing pod with certain attributes changed, for example changing the image tag to a new version.
- Workload: Add an ephemeral container to an already running pod, for example to add debugging utilities without restarting the pod.
- Node: Create a new pod that runs in the node's host namespaces and can access the node's filesystem.

```
kubectl debug (POD | TYPE[.VERSION].GROUP)/NAME) [-- COMMAND [args...]]
```

## Examples

```
Create an interactive debugging session in pod mypod and immediately attach to it.
kubectl debug mypod -it --image=busybox

Create an interactive debugging session for the pod in the file pod.yaml and immediately
attach to it.
(requires the EphemeralContainers feature to be enabled in the cluster)
kubectl debug -f pod.yaml -it --image=busybox

Create a debug container named debugger using a custom automated debugging image.
kubectl debug --image=myproj/debug-tools -c debugger mypod

Create a copy of mypod adding a debug container and attach to it
kubectl debug mypod -it --image=busybox --copy-to=my-debugger

Create a copy of mypod changing the command of mycontainer
kubectl debug mypod -it --copy-to=my-debugger --container=mycontainer -- sh

Create a copy of mypod changing all container images to busybox
kubectl debug mypod --copy-to=my-debugger --set-image=*=busybox

Create a copy of mypod adding a debug container and changing container images
kubectl debug mypod -it --copy-to=my-debugger --image=debian --set-
image=app=app:debug,sidecar=sidecar:debug

Create an interactive debugging session on a node and immediately attach to it.
The container will run in the host namespaces and the host's filesystem will be mounted at /
host
kubectl debug node/mynode -it --image=busybox
```

## Options

| --arguments-only                                                                                  |
|---------------------------------------------------------------------------------------------------|
| If specified, everything after -- will be passed to the new container as Args instead of Command. |
| --attach                                                                                          |

|                            |                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | If true, wait for the container to start running, and then attach as if 'kubectl attach ...' were called. Default false, unless '-i/--stdin' is set, in which case the default is true. |
| -c, --container string     |                                                                                                                                                                                         |
|                            | Container name to use for debug container.                                                                                                                                              |
| --copy-to string           |                                                                                                                                                                                         |
|                            | Create a copy of the target Pod with this name.                                                                                                                                         |
| --env stringToString       | Default: []                                                                                                                                                                             |
|                            | Environment variables to set in the container.                                                                                                                                          |
| -f, --filename strings     |                                                                                                                                                                                         |
|                            | identifying the resource to debug                                                                                                                                                       |
| -h, --help                 |                                                                                                                                                                                         |

| --image string             |                                                                                                                                                                                         |
|                            | Container image to use for debug container.                                                                                                                                             |
| --image-pull-policy string |                                                                                                                                                                                         |
|                            | The image pull policy for the container. If left empty, this value will not be specified by the client and defaulted by the server.                                                     |
| --profile string           | Default: "legacy"                                                                                                                                                                       |
|                            | Options are "legacy", "general", "baseline", "netadmin", "restricted" or "sysadmin".                                                                                                    |
| -q, --quiet                |                                                                                                                                                                                         |
|                            | If true, suppress informational messages.                                                                                                                                               |
| --replace                  |                                                                                                                                                                                         |
|                            | When used with '--copy-to', delete the original Pod.                                                                                                                                    |
| --same-node                |                                                                                                                                                                                         |
|                            | When used with '--copy-to', schedule the copy of target Pod on the same node.                                                                                                           |
| --set-image stringToString | Default: []                                                                                                                                                                             |

|                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------|
| When used with '--copy-to', a list of name=image pairs for changing container images, similar to how 'kubectl set image' works. |
| --share-processes    Default: true                                                                                              |
| When used with '--copy-to', enable process namespace sharing in the copy.                                                       |
| -i, --stdin                                                                                                                     |
| Keep stdin open on the container(s) in the pod, even if nothing is attached.                                                    |
| --target string                                                                                                                 |
| When using an ephemeral container, target processes in this container name.                                                     |
| -t, --tty                                                                                                                       |
| Allocate a TTY for the debugging container.                                                                                     |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                          |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                           |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                             |

|                                           |                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                           | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                  | Default: "0"                                                                                                                                                                                      |
|                                           | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                       |                                                                                                                                                                                                   |
|                                           | The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration | Default: 1m0s                                                                                                                                                                                     |
|                                           | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string                | Default: "cadvisor"                                                                                                                                                                               |
|                                           | database name                                                                                                                                                                                     |
| --storage-driver-host string              | Default: "localhost:8086"                                                                                                                                                                         |
|                                           | database host:port                                                                                                                                                                                |
| --storage-driver-password string          | Default: "root"                                                                                                                                                                                   |
|                                           | database password                                                                                                                                                                                 |
| --storage-driver-secure                   |                                                                                                                                                                                                   |
|                                           | use secure connection with database                                                                                                                                                               |
| --storage-driver-table string             | Default: "stats"                                                                                                                                                                                  |
|                                           | table name                                                                                                                                                                                        |
| --storage-driver-user string              | Default: "root"                                                                                                                                                                                   |
|                                           | database username                                                                                                                                                                                 |
| --tls-server-name string                  |                                                                                                                                                                                                   |
|                                           | Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                            |                                                                                                                                                                                                   |
|                                           | Bearer token for authentication to the API server                                                                                                                                                 |
| --user string                             |                                                                                                                                                                                                   |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

# kubectl delete

## Synopsis

Delete resources by file names, stdin, resources and names, or by resources and label selector.

JSON and YAML formats are accepted. Only one type of argument may be specified: file names, resources and names, or resources and label selector.

Some resources, such as pods, support graceful deletion. These resources define a default period before they are forcibly terminated (the grace period) but you may override that value with the --grace-period flag, or pass --now to set a grace-period of 1. Because these resources often represent entities in the cluster, deletion may not be acknowledged immediately. If the node hosting a pod is down or cannot reach the API server, termination may take significantly longer than the grace period. To force delete a resource, you must specify the --force flag. Note: only a subset of resources support graceful deletion. In absence of the support, the --grace-period flag is ignored.

**IMPORTANT:** Force deleting pods does not wait for confirmation that the pod's processes have been terminated, which can leave those processes running until the node detects the deletion and completes graceful deletion. If your processes use shared storage or talk to a remote API and depend on the name of the pod to identify themselves, force deleting those pods may result in multiple processes running on different machines using the same identification which may lead to data corruption or inconsistency. Only force delete pods when you are sure the pod is terminated, or if your application can tolerate multiple copies of the same pod running at once. Also, if you force delete pods, the scheduler may place new pods on those nodes before the node has released those resources and causing those pods to be evicted immediately.

Note that the delete command does NOT do resource version checks, so if someone submits an update to a resource right when you submit a delete, their update will be lost along with the rest of the resource.

After a CustomResourceDefinition is deleted, invalidation of discovery cache may take up to 6 hours. If you don't want to wait, you might want to run "kubectl api-resources" to refresh the discovery cache.

```
kubectl delete ([-f FILENAME] | [-k DIRECTORY] | TYPE [(NAME | -l label | --all)])
```

## Examples

```
Delete a pod using the type and name specified in pod.json
kubectl delete -f ./pod.json

Delete resources from a directory containing kustomization.yaml - e.g. dir/
kustomization.yaml
kubectl delete -k dir

Delete resources from all files that end with '.json'
kubectl delete -f '*.json'

Delete a pod based on the type and name in the JSON passed into stdin
cat pod.json | kubectl delete -f -

Delete pods and services with same names "baz" and "foo"
kubectl delete pod,service baz foo

Delete pods and services with label name=myLabel
kubectl delete pods,services -l name=myLabel

Delete a pod with minimal delay
kubectl delete pod foo --now

Force delete a pod on a dead node
kubectl delete pod foo --force

Delete all pods
kubectl delete pods --all
```

## Options

|                                                                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------------------|
| --all                                                                                                                                       |
| Delete all resources, in the namespace of the specified resource types.                                                                     |
| -A, --all-namespaces                                                                                                                        |
| If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace. |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--cascade string[="background"]</code> Default: "background"                                                                                                                                       |
| Must be "background", "orphan", or "foreground". Selects the deletion cascading strategy for the dependents (e.g. Pods created by a ReplicationController). Defaults to background.                      |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                              |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| <code>--field-selector string</code>                                                                                                                                                                     |
| Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. <code>--field-selector key1=value1,key2=value2</code> ). The server only supports a limited number of field queries per type.    |
| <code>-f, --filename strings</code>                                                                                                                                                                      |
| containing the resource to delete.                                                                                                                                                                       |
| <code>--force</code>                                                                                                                                                                                     |
| If true, immediately remove resources from API and bypass graceful deletion. Note that immediate deletion of some resources may result in inconsistency or data loss and requires confirmation.          |
| <code>--grace-period int</code> Default: -1                                                                                                                                                              |
| Period of time in seconds given to the resource to terminate gracefully. Ignored if negative. Set to 1 for immediate shutdown. Can only be set to 0 when <code>--force</code> is true (force deletion).  |
| <code>-h, --help</code>                                                                                                                                                                                  |
| help for delete                                                                                                                                                                                          |
| <code>--ignore-not-found</code>                                                                                                                                                                          |
| Treat "resource not found" as a successful delete. Defaults to "true" when <code>--all</code> is specified.                                                                                              |
| <code>-i, --interactive</code>                                                                                                                                                                           |
| If true, delete resource only when user confirms.                                                                                                                                                        |
| <code>-k, --kustomize string</code>                                                                                                                                                                      |
| Process a kustomization directory. This flag can't be used together with <code>-f</code> or <code>-R</code> .                                                                                            |
| <code>--now</code>                                                                                                                                                                                       |
| If true, resources are signaled for immediate shutdown (same as <code>--grace-period=1</code> ).                                                                                                         |

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -o, --output string                                                                                                                                                        |
| Output mode. Use "-o name" for shorter output (resource/name).                                                                                                             |
| --raw string                                                                                                                                                               |
| Raw URI to DELETE to the server. Uses the transport specified by the kubeconfig file.                                                                                      |
| -R, --recursive                                                                                                                                                            |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                            |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --timeout duration                                                                                                                                                         |
| The length of time to wait before giving up on a delete, zero means determine a timeout from the size of the object                                                        |
| --wait     Default: true                                                                                                                                                   |
| If true, wait for resources to be gone before returning. This waits for finalizers.                                                                                        |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string     Default: "\$HOME/.kube/cache"                                                         |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectrl describe

## Synopsis

Show details of a specific resource or group of resources.

Print a detailed description of the selected resources, including related resources such as events or controllers. You may select a single object by name, all objects of that type, provide a name prefix, or label selector. For example:

```
$ kubectrl describe TYPE NAME_PREFIX
```

will first check for an exact match on TYPE and NAME\_PREFIX. If no such resource exists, it will output details for every resource that has a name prefixed with NAME\_PREFIX.

Use "kubectrl api-resources" for a complete list of supported resources.

kubectl describe (-f FILENAME | TYPE [NAME\_PREFIX | -l label] | TYPE/NAME)

# Examples

```
Describe a node
kubectl describe nodes kubernetes-node-emt8.c.myproject.internal

Describe a pod
kubectl describe pods/nginx

Describe a pod identified by type and name in "pod.json"
kubectl describe -f pod.json

Describe all pods
kubectl describe pods

Describe pods by label name=myLabel
kubectl describe pods -l name=myLabel

Describe all pods managed by the 'frontend' replication controller
(rc-created pods get the name of the rc as a prefix in the pod name)
kubectl describe pods frontend
```

# Options

|                                                                                                                                             |
|---------------------------------------------------------------------------------------------------------------------------------------------|
| -A, --all-namespaces                                                                                                                        |
| If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace. |
| --chunk-size int    Default: 500                                                                                                            |
| Return large lists in chunks rather than all at once. Pass 0 to disable. This flag is beta and may change in the future.                    |
| -f, --filename strings                                                                                                                      |
| Filename, directory, or URL to files containing the resource to describe                                                                    |
| -h, --help                                                                                                                                  |
| help for describe                                                                                                                           |
| -k, --kustomize string                                                                                                                      |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                        |
| -R, --recursive                                                                                                                             |

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                            |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --show-events    Default: true                                                                                                                                             |
| If true, display events related to the described object.                                                                                                                   |

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                             |

# kubectrl diff

## Synopsis

Diff configurations specified by file name or stdin between the current online configuration, and the configuration as it would be if applied.

The output is always YAML.

KUBECTL\_EXTERNAL\_DIFF environment variable can be used to select your own diff command. Users can use external commands with params too, example:  
KUBECTL\_EXTERNAL\_DIFF="colordiff -N -u"

By default, the "diff" command available in your path will be run with the "-u" (unified diff) and "-N" (treat absent files as empty) options.

Exit status: 0 No differences were found. 1 Differences were found. >1 Kubectrl or diff failed with an error.

Note: KUBECTL\_EXTERNAL\_DIFF, if used, is expected to follow that convention.

```
kubectrl diff -f FILENAME
```

## Examples

```
Diff resources included in pod.json
kubectrl diff -f pod.json

Diff file read from stdin
cat service.yaml | kubectrl diff -f -
```

# Options

|                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --concurrency int    Default: 1                                                                                                                                            |
| Number of objects to process in parallel when diffing against the live version. Larger number = faster, but more memory, I/O and CPU over that shorter period of time.     |
| --field-manager string    Default: "kubectl-client-side-apply"                                                                                                             |
| Name of the manager used to track field ownership.                                                                                                                         |
| -f, --filename strings                                                                                                                                                     |
| Filename, directory, or URL to files contains the configuration to diff                                                                                                    |
| --force-conflicts                                                                                                                                                          |
| If true, server-side apply will force the changes against conflicts.                                                                                                       |
| -h, --help                                                                                                                                                                 |
| help for diff                                                                                                                                                              |
| -k, --kustomize string                                                                                                                                                     |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                       |
| --prune                                                                                                                                                                    |
| Include resources that would be deleted by pruning. Can be used with -l and default shows all resources would be pruned                                                    |
| --prune-allowlist strings                                                                                                                                                  |
| Overwrite the default allowlist with <group/version/kind> for --prune                                                                                                      |
| -R, --recursive                                                                                                                                                            |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                            |
| -l, --selector string                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints. |
| --server-side                                                                                                                                                              |
| If true, apply runs in the server instead of the client.                                                                                                                   |
| --show-managed-fields                                                                                                                                                      |

If true, include managed fields in the diff.

--as string

Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

--as-group strings

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.

--as-uid string

UID to impersonate for the operation.

--cache-dir string Default: "\$HOME/.kube/cache"

Default cache directory

--certificate-authority string

Path to a cert file for the certificate authority

--client-certificate string

Path to a client certificate file for TLS

--client-key string

Path to a client key file for TLS

--cloud-provider-gce-l7lb-src-cidrs cidrs Default: 130.211.0.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks

--cloud-provider-gce-lb-src-cidrs cidrs Default:  
130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks

--cluster string

The name of the kubeconfig cluster to use

--context string

The name of the kubeconfig context to use

--default-not-ready-toleration-seconds int Default: 300

|                                              |                                                                                                                                                                                                   |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int | Default: 300                                                                                                                                                                                      |
|                                              | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                        |                                                                                                                                                                                                   |
|                                              | If true, opt-out of response compression for all requests to the server                                                                                                                           |

# kubectl drain

## Synopsis

Drain node in preparation for maintenance.

The given node will be marked unschedulable to prevent new pods from arriving. 'drain' evicts the pods if the API server supports <https://kubernetes.io/docs/concepts/workloads/pods/disruptions/> eviction <https://kubernetes.io/docs/concepts/workloads/pods/disruptions/> . Otherwise, it will use normal DELETE to delete the pods. The 'drain' evicts or deletes all pods except mirror pods (which cannot be deleted through the API server). If there are daemon set-managed pods, drain will not proceed without --ignore-daemonsets, and regardless it will not delete any daemon set-managed pods, because those pods would be immediately replaced by the daemon set controller, which ignores unschedulable markings. If there are any pods that are neither mirror pods nor managed by a replication controller, replica set, daemon set, stateful set, or job, then drain will not delete any pods unless you use --force. --force will also allow deletion to proceed if the managing resource of one or more pods is missing.

'drain' waits for graceful termination. You should not operate on the machine until the command completes.

When you are ready to put the node back into service, use `kubectl uncordon`, which will make the node schedulable again.

[https://kubernetes.io/images/docs/kubectl\\_drain.svg](https://kubernetes.io/images/docs/kubectl_drain.svg) Workflow[https://kubernetes.io/images/docs/kubectl\\_drain.svg](https://kubernetes.io/images/docs/kubectl_drain.svg)

```
kubectl drain NODE
```

## Examples

```
Drain node "foo", even if there are pods not managed by a replication controller, replica set, job, daemon set, or stateful set on it
kubectl drain foo --force
```

```
As above, but abort if there are pods not managed by a replication controller, replica set, job, daemon set, or stateful set, and use a grace period of 15 minutes
kubectl drain foo --grace-period=900
```

|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--chunk-size int</code> Default: 500                                                                                                                                                               |
| Return large lists in chunks rather than all at once. Pass 0 to disable. This flag is beta and may change in the future.                                                                                 |
| <code>--delete-emptydir-data</code>                                                                                                                                                                      |
| Continue even if there are pods using emptyDir (local data that will be deleted when the node is drained).                                                                                               |
| <code>--disable-eviction</code>                                                                                                                                                                          |
| Force drain to use delete, even if eviction is supported. This will bypass checking PodDisruptionBudgets, use with caution.                                                                              |
| <code>--dry-run string[="unchanged"]</code> Default: "none"                                                                                                                                              |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| <code>--force</code>                                                                                                                                                                                     |
| Continue even if there are pods that do not declare a controller.                                                                                                                                        |
| <code>--grace-period int</code> Default: -1                                                                                                                                                              |
| Period of time in seconds given to each pod to terminate gracefully. If negative, the default value specified in the pod will be used.                                                                   |
| <code>-h, --help</code>                                                                                                                                                                                  |
| help for drain                                                                                                                                                                                           |
| <code>--ignore-daemonsets</code>                                                                                                                                                                         |
| Ignore DaemonSet-managed pods.                                                                                                                                                                           |
| <code>--pod-selector string</code>                                                                                                                                                                       |
| Label selector to filter pods on the node                                                                                                                                                                |
| <code>-l, --selector string</code>                                                                                                                                                                       |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                               |
| <code>--skip-wait-for-delete-timeout int</code>                                                                                                                                                          |

|                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------|
| If pod DeletionTimestamp older than N seconds, skip waiting for the pod. Seconds must be greater than 0 to skip.   |
| --timeout duration                                                                                                 |
| The length of time to wait before giving up, zero means infinite                                                   |
| --as string                                                                                                        |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.       |
| --as-group strings                                                                                                 |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                      |
| --as-uid string                                                                                                    |
| UID to impersonate for the operation.                                                                              |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                            |
| --certificate-authority string                                                                                     |
| Path to a cert file for the certificate authority                                                                  |
| --client-certificate string                                                                                        |
| Path to a client certificate file for TLS                                                                          |
| --client-key string                                                                                                |
| Path to a client key file for TLS                                                                                  |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                               |

# kubectl edit

## Synopsis

Edit a resource from the default editor.

The edit command allows you to directly edit any API resource you can retrieve via the command-line tools. It will open the editor defined by your KUBE\_EDITOR, or EDITOR environment variables, or fall back to 'vi' for Linux or 'notepad' for Windows. When attempting to open the editor, it will first attempt to use the shell that has been defined in the 'SHELL' environment variable. If this is not defined, the default shell will be used, which is '/bin/bash' for Linux or 'cmd' for Windows.

You can edit multiple objects, although changes are applied one at a time. The command accepts file names as well as command-line arguments, although the files you point to must be previously saved versions of resources.

Editing is done with the API version used to fetch the resource. To edit using a specific API version, fully-qualify the resource, version, and group.

The default format is YAML. To edit in JSON, specify "-o json".

The flag --windows-line-endings can be used to force Windows line endings, otherwise the default for your operating system will be used.

In the event an error occurs while updating, a temporary file will be created on disk that contains your unapplied changes. The most common error when updating a resource is another editor changing the resource on the server. When this occurs, you will have to apply your changes to the newer version of the resource, or update your temporary saved copy to include the latest resource version.

```
kubectl edit (RESOURCE/NAME | -f FILENAME)
```

## Examples

```
Edit the service named 'registry'
kubectl edit svc/registry
```

```
Use an alternative editor
KUBE_EDITOR="nano" kubectl edit svc/registry

Edit the job 'myjob' in JSON using the v1 API format
kubectl edit job.v1.batch/myjob -o json

Edit the deployment 'mydeployment' in YAML and save the modified config in its annotation
kubectl edit deployment/mydeployment -o yaml --save-config

Edit the 'status' subresource for the 'mydeployment' deployment
kubectl edit deployment mydeployment --subresource='status'
```

## Options

|                                                                                                                                                              |                         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <code>--allow-missing-template-keys</code>                                                                                                                   | Default: true           |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.              |                         |
| <code>--field-manager</code> string                                                                                                                          | Default: "kubectl-edit" |
| Name of the manager used to track field ownership.                                                                                                           |                         |
| <code>-f, --filename</code> strings                                                                                                                          |                         |
| Filename, directory, or URL to files to use to edit the resource                                                                                             |                         |
| <code>-h, --help</code>                                                                                                                                      |                         |
| help for edit                                                                                                                                                |                         |
| <code>-k, --kustomize</code> string                                                                                                                          |                         |
| Process the kustomization directory. This flag can't be used together with <code>-f</code> or <code>-R</code> .                                              |                         |
| <code>-o, --output</code> string                                                                                                                             |                         |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                 |                         |
| <code>--output-patch</code>                                                                                                                                  |                         |
| Output the patch if the resource is edited.                                                                                                                  |                         |
| <code>-R, --recursive</code>                                                                                                                                 |                         |
| Process the directory used in <code>-f, --filename</code> recursively. Useful when you want to manage related manifests organized within the same directory. |                         |

# kubectl events

## Synopsis

Display events.

Prints a table of the most important information about events. You can request events for a namespace, for all namespace, or filtered to only those pertaining to a specified resource.

```
kubectl events [(-o|--output=)json|yaml|name|go-template|go-template-file|template|templatefile|
jsonpath|jsonpath-as-json|jsonpath-file] [--for TYPE/NAME] [--watch] [--
types=Normal,Warning]
```

# Examples

```
List recent events in the default namespace
kubectl events

List recent events in all namespaces
kubectl events --all-namespaces

List recent events for the specified pod, then wait for more events and list them as they arrive
kubectl events --for pod/web-pod-13je7 --watch

List recent events in YAML format
kubectl events -oyaml

List recent only events of type 'Warning' or 'Normal'
kubectl events --types=Warning,Normal
```

# Options

|                                                                                                                                                  |
|--------------------------------------------------------------------------------------------------------------------------------------------------|
| -A, --all-namespaces                                                                                                                             |
| If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.      |
| --allow-missing-template-keys    Default: true                                                                                                   |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goolang and jsonpath output formats. |
| --chunk-size int    Default: 500                                                                                                                 |
| Return large lists in chunks rather than all at once. Pass 0 to disable. This flag is beta and may change in the future.                         |
| --for string                                                                                                                                     |
| Filter events to only those pertaining to the specified resource.                                                                                |
| -h, --help                                                                                                                                       |
| help for events                                                                                                                                  |
| --no-headers                                                                                                                                     |
| When using the default output format, don't print headers.                                                                                       |
| -o, --output string                                                                                                                              |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                                                             |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --types strings                                                                                                                                                                                                                                          |
| Output only events of given types.                                                                                                                                                                                                                       |
| -w, --watch                                                                                                                                                                                                                                              |
| After listing the requested events, watch for more events.                                                                                                                                                                                               |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |
| Path to a client key file for TLS                                                                            |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                            |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |
| Password for basic authentication to the API server                                                                                                             |
| --profile string    Default: "none"                                                                                                                             |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string    Default: "profile.pprof"                                                                                                                                               |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string    Default: "0"                                                                                                                                                          |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string    Default: "cadvisor"                                                                                                                                                 |
| database name                                                                                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                                                                                         |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                                                                                               |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                                                                                 |
| table name                                                                                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                                                                                   |
| database username                                                                                                                                                                                 |
| --tls-server-name string                                                                                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used                                                                      |
| --token string                                                                                                                                                                                    |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| Bearer token for authentication to the API server                                                            |
| --user string                                                                                                |
| The name of the kubeconfig user to use                                                                       |
| --username string                                                                                            |
| Username for basic authentication to the API server                                                          |
| --version version[=true]                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version |
| --warnings-as-errors                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                         |

# kubectl exec

## Synopsis

Execute a command in a container.

```
kubectl exec (POD | TYPE/NAME) [-c CONTAINER] [flags] -- COMMAND [args...]
```

## Examples

```
Get output from running the 'date' command from pod mypod, using the first container by default
```

```
kubectl exec mypod -- date
```

```
Get output from running the 'date' command in ruby-container from pod mypod
```

```
kubectl exec mypod -c ruby-container -- date
```

```
Switch to raw terminal mode; sends stdin to 'bash' in ruby-container from pod mypod
```

```
and sends stdout/stderr from 'bash' back to the client
```

```
kubectl exec mypod -c ruby-container -i -t -- bash -il
```

```
List contents of /usr from the first container of pod mypod and sort by modification time
```

```
If the command you want to execute in the pod has any flags in common (e.g. -i),
```

```
you must use two dashes (--) to separate your command's flags/arguments
```

```
Also note, do not surround your command and its flags/arguments with quotes
unless that is how you would execute it normally (i.e., do ls -t /usr, not "ls -t /usr")
kubectl exec mypod -i -t -- ls -t /usr
```

```
Get output from running 'date' command from the first pod of the deployment
mydeployment, using the first container by default
kubectl exec deploy/mydeployment -- date
```

```
Get output from running 'date' command from the first pod of the service myservice, using
the first container by default
kubectl exec svc/myservice -- date
```

## Options

|                                                 |                                                                                                                                                                                    |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c, --container string                          | Container name. If omitted, use the kubectl.kubernetes.io/default-container annotation for selecting the container to be attached or the first container in the pod will be chosen |
| -f, --filename strings                          | to use to exec into the resource                                                                                                                                                   |
| -h, --help                                      | help for exec                                                                                                                                                                      |
| --pod-running-timeout duration    Default: 1m0s | The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running                                                                                |
| -q, --quiet                                     | Only print output from the remote session                                                                                                                                          |
| -i, --stdin                                     | Pass stdin to the container                                                                                                                                                        |
| -t, --tty                                       | Stdin is a TTY                                                                                                                                                                     |
| --as string                                     | Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                       |
| --as-group strings                              |                                                                                                                                                                                    |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                   |
| --as-uid string                                                                                                                                                 |
| UID to impersonate for the operation.                                                                                                                           |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                              |
| Default cache directory                                                                                                                                         |
| --certificate-authority string                                                                                                                                  |
| Path to a cert file for the certificate authority                                                                                                               |
| --client-certificate string                                                                                                                                     |
| Path to a client certificate file for TLS                                                                                                                       |
| --client-key string                                                                                                                                             |
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs   Default: 130.211.0.0/22,35.191.0.0/16                                                                               |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs   Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                              |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int   Default: 300                                                                                                       |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int   Default: 300                                                                                                     |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |

|  |                                                                                                                                                                                                   |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | If true, opt-out of response compression for all requests to the server                                                                                                                           |
|  | <code>--insecure-skip-tls-verify</code>                                                                                                                                                           |
|  | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
|  | <code>--kubeconfig string</code>                                                                                                                                                                  |
|  | Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
|  | <code>--match-server-version</code>                                                                                                                                                               |
|  | Require server version to match client version                                                                                                                                                    |
|  | <code>-n, --namespace string</code>                                                                                                                                                               |
|  | If present, the namespace scope for this CLI request                                                                                                                                              |
|  | <code>--password string</code>                                                                                                                                                                    |
|  | Password for basic authentication to the API server                                                                                                                                               |
|  | <code>--profile string</code> Default: "none"                                                                                                                                                     |
|  | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
|  | <code>--profile-output string</code> Default: "profile.pprof"                                                                                                                                     |
|  | Name of the file to write the profile to                                                                                                                                                          |
|  | <code>--request-timeout string</code> Default: "0"                                                                                                                                                |
|  | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
|  | <code>-s, --server string</code>                                                                                                                                                                  |
|  | The address and port of the Kubernetes API server                                                                                                                                                 |
|  | <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                                                                                              |
|  | Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
|  | <code>--storage-driver-db string</code> Default: "cadvisor"                                                                                                                                       |
|  | database name                                                                                                                                                                                     |
|  | <code>--storage-driver-host string</code> Default: "localhost:8086"                                                                                                                               |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database host:port                                                                                                           |
| --storage-driver-password string    Default: "root"                                                                          |
| database password                                                                                                            |
| --storage-driver-secure                                                                                                      |
| use secure connection with database                                                                                          |
| --storage-driver-table string    Default: "stats"                                                                            |
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

# kubectl explain

## Synopsis

Describe fields and structure of various resources.

This command describes the fields associated with each supported API resource. Fields are identified via a simple JSONPath identifier:

```
<type>.<fieldName>[.<fieldName>]
```

Information about each field is retrieved from the server in OpenAPI format.

Use "kubectl api-resources" for a complete list of supported resources.

```
kubectl explain TYPE [--recursive=FALSE|TRUE] [--api-version=api-version-group] [--output=plaintext|plaintext-openapiv2]
```

## Examples

```
Get the documentation of the resource and its fields
kubectl explain pods

Get all the fields in the resource
kubectl explain pods --recursive

Get the explanation for deployment in supported api versions
kubectl explain deployments --api-version=apps/v1

Get the documentation of a specific field of a resource
kubectl explain pods.spec.containers

Get the documentation of resources in different format
kubectl explain deployment --output=plaintext-openapiv2
```

## Options

| --api-version string                                                                      |
|-------------------------------------------------------------------------------------------|
| Use given api-version (group/version) of the resource.                                    |
| -h, --help                                                                                |
| help for explain                                                                          |
| --output string   Default: "plaintext"                                                    |
| Format in which to render the schema. Valid values are: (plaintext, plaintext-openapiv2). |
| --recursive                                                                               |

When true, print the name of all the fields recursively. Otherwise, print the available fields with their description.

--as string

Username to impersonate for the operation. User could be a regular user or a service account in a namespace.

--as-group strings

Group to impersonate for the operation, this flag can be repeated to specify multiple groups.

--as-uid string

UID to impersonate for the operation.

--cache-dir string Default: "\$HOME/.kube/cache"

Default cache directory

--certificate-authority string

Path to a cert file for the certificate authority

--client-certificate string

Path to a client certificate file for TLS

--client-key string

Path to a client key file for TLS

--cloud-provider-gce-l7lb-src-cidrs cidrs Default: 130.211.0.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks

--cloud-provider-gce-lb-src-cidrs cidrs Default:  
130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16

CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks

--cluster string

The name of the kubeconfig cluster to use

--context string

The name of the kubeconfig context to use

--default-not-ready-toleration-seconds int Default: 300

|                                              |                                                                                                                                                                                                   |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                              | Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.                                      |
| --default-unreachable-toleration-seconds int | Default: 300                                                                                                                                                                                      |
|                                              | Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration.                                   |
| --disable-compression                        |                                                                                                                                                                                                   |
|                                              | If true, opt-out of response compression for all requests to the server                                                                                                                           |
| --insecure-skip-tls-verify                   |                                                                                                                                                                                                   |
|                                              | If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                                                                |
| --kubeconfig string                          |                                                                                                                                                                                                   |
|                                              | Path to the kubeconfig file to use for CLI requests.                                                                                                                                              |
| --match-server-version                       |                                                                                                                                                                                                   |
|                                              | Require server version to match client version                                                                                                                                                    |

|                                              | Password for basic authentication to the API server                                                                                                                                               |
| --profile string                             | Default: "none"                                                                                                                                                                                   |
|                                              | Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string                      | Default: "profile.pprof"                                                                                                                                                                          |
|                                              | Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string                     | Default: "0"                                                                                                                                                                                      |
|                                              | The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                          |                                                                                                                                                                                                   |
|                                              | The address and port of the Kubernetes API server                                                                                                                                                 |

|                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------|
| --storage-driver-buffer-duration duration    Default: 1m0s                                                                        |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction |
| --storage-driver-db string    Default: "cadvisor"                                                                                 |
| database name                                                                                                                     |
| --storage-driver-host string    Default: "localhost:8086"                                                                         |
| database host:port                                                                                                                |
| --storage-driver-password string    Default: "root"                                                                               |
| database password                                                                                                                 |
| --storage-driver-secure                                                                                                           |
| use secure connection with database                                                                                               |
| --storage-driver-table string    Default: "stats"                                                                                 |
| table name                                                                                                                        |
| --storage-driver-user string    Default: "root"                                                                                   |
| database username                                                                                                                 |
| --tls-server-name string                                                                                                          |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used      |
| --token string                                                                                                                    |
| Bearer token for authentication to the API server                                                                                 |
| --user string                                                                                                                     |
| The name of the kubeconfig user to use                                                                                            |
| --username string                                                                                                                 |
| Username for basic authentication to the API server                                                                               |
| --version version[=true]                                                                                                          |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                      |
| --warnings-as-errors                                                                                                              |

Treat warnings received from the server as errors and exit with a non-zero exit code

# kubectl expose

## Synopsis

Expose a resource as a new Kubernetes service.

Looks up a deployment, service, replica set, replication controller or pod by name and uses the selector for that resource as the selector for a new service on the specified port. A deployment or replica set will be exposed as a service only if its selector is convertible to a selector that service supports, i.e. when the selector contains only the matchLabels component. Note that if no port is specified via `--port` and the exposed resource has multiple ports, all will be re-used by the new service. Also if no labels are specified, the new service will re-use the labels from the resource it exposes.

Possible resources include (case insensitive):

pod (po), service (svc), replicationcontroller (rc), deployment (deploy), replicaset (rs)

```
kubectl expose (-f FILENAME | TYPE NAME) [--port=port] [--protocol=TCP|UDP|SCTP] [--target-port=number-or-name] [--name=name] [--external-ip=external-ip-of-service] [--type=type]
```

## Examples

```
Create a service for a replicated nginx, which serves on port 80 and connects to the containers on port 8000
```

```
kubectl expose rc nginx --port=80 --target-port=8000
```

```
Create a service for a replication controller identified by type and name specified in "nginx-controller.yaml", which serves on port 80 and connects to the containers on port 8000
```

```
kubectl expose -f nginx-controller.yaml --port=80 --target-port=8000
```

```
Create a service for a pod valid-pod, which serves on port 444 with the name "frontend"
```

```
kubectl expose pod valid-pod --port=444 --name=frontend
```

```
Create a second service based on the above service, exposing the container port 8443 as port 443 with the name "nginx-https"
```

```
kubectl expose service nginx --port=443 --target-port=8443 --name=nginx-https
```

```
Create a service for a replicated streaming application on port 4100 balancing UDP traffic and named 'video-stream'.
```

```
kubectl expose rc streamer --port=4100 --protocol=UDP --name=video-stream
```

```
Create a service for a replicated nginx using replica set, which serves on port 80 and
connects to the containers on port 8000
kubectl expose rs nginx --port=80 --target-port=8000

Create a service for an nginx deployment, which serves on port 80 and connects to the
containers on port 8000
kubectl expose deployment nginx --port=80 --target-port=8000
```

## Options

|                                                                                                                                                                                                          |                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| <code>--allow-missing-template-keys</code>                                                                                                                                                               | Default: true                        |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats.                                                          |                                      |
| <code>--cluster-ip</code>                                                                                                                                                                                | string                               |
| ClusterIP to be assigned to the service. Leave empty to auto-allocate, or set to 'None' to create a headless service.                                                                                    |                                      |
| <code>--dry-run</code>                                                                                                                                                                                   | string[="unchanged"] Default: "none" |
| Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |                                      |
| <code>--external-ip</code>                                                                                                                                                                               | string                               |
| Additional external IP address (not managed by Kubernetes) to accept for the service. If this IP is routed to a node, the service can be accessed by this IP in addition to its generated service IP.    |                                      |
| <code>--field-manager</code>                                                                                                                                                                             | string Default: "kubectl-expose"     |
| Name of the manager used to track field ownership.                                                                                                                                                       |                                      |
| <code>-f, --filename</code>                                                                                                                                                                              | strings                              |
| Filename, directory, or URL to files identifying the resource to expose a service                                                                                                                        |                                      |
| <code>-h, --help</code>                                                                                                                                                                                  |                                      |
| help for expose                                                                                                                                                                                          |                                      |
| <code>-k, --kustomize</code>                                                                                                                                                                             | string                               |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                                     |                                      |
| <code>-l, --labels</code>                                                                                                                                                                                | string                               |

|  |                                                                                                                                                                                                                     |
|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Labels to apply to the service created by this call.                                                                                                                                                                |
|  | --load-balancer-ip string                                                                                                                                                                                           |
|  | IP to assign to the LoadBalancer. If empty, an ephemeral IP will be created and used (cloud-provider specific).                                                                                                     |
|  | --name string                                                                                                                                                                                                       |
|  | The name for the newly created object.                                                                                                                                                                              |
|  | -o, --output string                                                                                                                                                                                                 |
|  | Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                                                        |
|  | --override-type string   Default: "merge"                                                                                                                                                                           |
|  | The method used to override the generated object: json, merge, or strategic.                                                                                                                                        |
|  | --overrides string                                                                                                                                                                                                  |
|  | An inline JSON override for the generated object. If this is non-empty, it is used to override the generated object. Requires that the object supply a valid apiVersion field.                                      |
|  | --port string                                                                                                                                                                                                       |
|  | The port that the service should serve on. Copied from the resource being exposed, if unspecified                                                                                                                   |
|  | --protocol string                                                                                                                                                                                                   |
|  | The network protocol for the service to be created. Default is 'TCP'.                                                                                                                                               |
|  | -R, --recursive                                                                                                                                                                                                     |
|  | Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                     |
|  | --save-config                                                                                                                                                                                                       |
|  | If true, the configuration of current object will be saved in its annotation. Otherwise, the annotation will be unchanged. This flag is useful when you want to perform kubectl apply on this object in the future. |
|  | --selector string                                                                                                                                                                                                   |
|  | A label selector to use for this service. Only equality-based selector requirements are supported. If empty (the default) infer the selector from the replication controller or replica set.)                       |

|                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --session-affinity string                                                                                                                                                                                                                                |
| If non-empty, set the session affinity for the service to this; legal values: 'None', 'ClientIP'                                                                                                                                                         |
| --show-managed-fields                                                                                                                                                                                                                                    |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                            |
| --target-port string                                                                                                                                                                                                                                     |
| Name or number for the port on the container that the service should direct traffic to.<br>Optional.                                                                                                                                                     |
| --template string                                                                                                                                                                                                                                        |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --type string                                                                                                                                                                                                                                            |
| Type for this service: ClusterIP, NodePort, LoadBalancer, or ExternalName. Default is 'ClusterIP'.                                                                                                                                                       |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| --as string                                                                                                  |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| --as-group strings                                                                                           |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| --as-uid string                                                                                              |
| UID to impersonate for the operation.                                                                        |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                           |
| Default cache directory                                                                                      |
| --certificate-authority string                                                                               |
| Path to a cert file for the certificate authority                                                            |
| --client-certificate string                                                                                  |
| Path to a client certificate file for TLS                                                                    |
| --client-key string                                                                                          |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a client key file for TLS                                                                                                                               |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                                                              |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                             |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| --cluster string                                                                                                                                                |
| The name of the kubeconfig cluster to use                                                                                                                       |
| --context string                                                                                                                                                |
| The name of the kubeconfig context to use                                                                                                                       |
| --default-not-ready-toleration-seconds int    Default: 300                                                                                                      |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| --default-unreachable-toleration-seconds int    Default: 300                                                                                                    |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| --disable-compression                                                                                                                                           |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| --insecure-skip-tls-verify                                                                                                                                      |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| --kubeconfig string                                                                                                                                             |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| --match-server-version                                                                                                                                          |
| Require server version to match client version                                                                                                                  |
| -n, --namespace string                                                                                                                                          |
| If present, the namespace scope for this CLI request                                                                                                            |
| --password string                                                                                                                                               |

|                                                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Password for basic authentication to the API server</p>                                                                                                                                               |
| <p>--profile string   Default: "none"</p>                                                                                                                                                                |
| <p>Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)</p>                                                                                                             |
| <p>--profile-output string   Default: "profile.pprof"</p>                                                                                                                                                |
| <p>Name of the file to write the profile to</p>                                                                                                                                                          |
| <p>--request-timeout string   Default: "0"</p>                                                                                                                                                           |
| <p>The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests.</p> |
| <p>-s, --server string</p>                                                                                                                                                                               |
| <p>The address and port of the Kubernetes API server</p>                                                                                                                                                 |
| <p>--storage-driver-buffer-duration duration   Default: 1m0s</p>                                                                                                                                         |
| <p>Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction</p>                                                                 |
| <p>--storage-driver-db string   Default: "cadvisor"</p>                                                                                                                                                  |
| <p>database name</p>                                                                                                                                                                                     |

# kubectrl get

## Synopsis

Display one or many resources.

Prints a table of the most important information about the specified resources. You can filter the list using a label selector and the --selector flag. If the desired resource type is namespaced you will only see results in your current namespace unless you pass --all-namespaces.

By specifying the output as 'template' and providing a Go template as the value of the --template flag, you can filter the attributes of the fetched resources.

Use "kubectrl api-resources" for a complete list of supported resources.

```
kubectrl get [(-o|--output=)json|yaml|name|go-template|go-template-file|template|templatefile|
jsonpath|jsonpath-as-json|jsonpath-file|custom-columns|custom-columns-file|wide]
(TYPE[.VERSION][.GROUP] [NAME | -l label] | TYPE[.VERSION][.GROUP]/NAME ...) [flags]
```

## Examples

```
List all pods in ps output format
kubectl get pods

List all pods in ps output format with more information (such as node name)
kubectl get pods -o wide

List a single replication controller with specified NAME in ps output format
kubectl get replicationcontroller web

List deployments in JSON output format, in the "v1" version of the "apps" API group
kubectl get deployments.v1.apps -o json

List a single pod in JSON output format
kubectl get -o json pod web-pod-13je7

List a pod identified by type and name specified in "pod.yaml" in JSON output format
kubectl get -f pod.yaml -o json

List resources from a directory with kustomization.yaml - e.g. dir/kustomization.yaml
kubectl get -k dir/

Return only the phase value of the specified pod
kubectl get -o template pod/web-pod-13je7 --template={{.status.phase}}

List resource information in custom columns
kubectl get pod test-pod -o custom-
columns=CONTAINER:.spec.containers[0].name,IMAGE:.spec.containers[0].image

List all replication controllers and services together in ps output format
kubectl get rc,services

List one or more resources by their type and names
kubectl get rc/web service/frontend pods/web-pod-13je7

List the 'status' subresource for a single pod
kubectl get pod web-pod-13je7 --subresource status
```

## Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| -A, --all-namespaces                                                                                                                            |
| If present, list the requested object(s) across all namespaces. Namespace in current context is ignored even if specified with --namespace.     |
| --allow-missing-template-keys    Default: true                                                                                                  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| <code>--chunk-size int</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Default: 500 |
| Return large lists in chunks rather than all at once. Pass 0 to disable. This flag is beta and may change in the future.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |              |
| <code>--field-selector string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |
| Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. <code>--field-selector key1=value1,key2=value2</code> ). The server only supports a limited number of field queries per type.                                                                                                                                                                                                                                                                                                                                                                                                                                                |              |
| <code>-f, --filename strings</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |
| Filename, directory, or URL to files identifying the resource to get from a server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |              |

| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file, custom-columns, custom-columns-file, wide). See custom columns [ <a href="https://kubernetes.io/docs/reference/kubectl/#custom-columns">https://kubernetes.io/docs/reference/kubectl/#custom-columns</a> ], golang template [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ] and jsonpath template [ <a href="https://kubernetes.io/docs/reference/kubectl/jsonpath/">https://kubernetes.io/docs/reference/kubectl/jsonpath/</a> ]. |              |
| <code>--output-watch-events</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |              |
| Output watch event objects when <code>--watch</code> or <code>--watch-only</code> is used. Existing objects are output as initial ADDED events.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |
| <code>--raw string</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |              |

|                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Raw URI to request from the server. Uses the transport specified by the kubeconfig file.                                                                                                                                                                   |
| -R, --recursive                                                                                                                                                                                                                                            |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                                                                                            |
| -l, --selector string                                                                                                                                                                                                                                      |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.                                                                                 |
| --server-print    Default: true                                                                                                                                                                                                                            |
| If true, have the server return the appropriate table output. Supports extension APIs and CRDs.                                                                                                                                                            |
| --show-kind                                                                                                                                                                                                                                                |
| If present, list the resource type for the requested object(s).                                                                                                                                                                                            |
| --show-labels                                                                                                                                                                                                                                              |
| When printing, show all labels as the last column (default hide labels column)                                                                                                                                                                             |
| --show-managed-fields                                                                                                                                                                                                                                      |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                              |
| --sort-by string                                                                                                                                                                                                                                           |
| If non-empty, sort list types using this field specification. The field specification is expressed as a JSONPath expression (e.g. '{.metadata.name}'). The field in the API resource specified by this JSONPath expression must be an integer or a string. |
| --subresource string                                                                                                                                                                                                                                       |
| If specified, gets the subresource of the requested object. Must be one of [status scale]. This flag is beta and may change in the future.                                                                                                                 |
| --template string                                                                                                                                                                                                                                          |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is golang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ].   |
| -w, --watch                                                                                                                                                                                                                                                |
| After listing/getting the requested object, watch for changes.                                                                                                                                                                                             |
| --watch-only                                                                                                                                                                                                                                               |

|                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------|
| Watch for changes to the requested object(s), without listing/getting first.                                        |
| --as string                                                                                                         |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.        |
| --as-group strings                                                                                                  |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                       |
| --as-uid string                                                                                                     |
| UID to impersonate for the operation.                                                                               |
| --cache-dir string    Default: "\$HOME/.kube/cache"                                                                 |
| Default cache directory                                                                                             |
| --certificate-authority string                                                                                      |
| Path to a cert file for the certificate authority                                                                   |
| --client-certificate string                                                                                         |
| Path to a client certificate file for TLS                                                                           |
| --client-key string                                                                                                 |
| Path to a client key file for TLS                                                                                   |
| --cloud-provider-gce-l7lb-src-cidrs cidrs    Default: 130.211.0.0/22,35.191.0.0/16                                  |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                |
| --cloud-provider-gce-lb-src-cidrs cidrs    Default:<br>130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16 |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                |
| --cluster string                                                                                                    |
| The name of the kubeconfig cluster to use                                                                           |

# kubectl kustomize

## Synopsis

Build a set of KRM resources using a 'kustomization.yaml' file. The DIR argument must be a path to a directory containing 'kustomization.yaml', or a git repository URL with a path suffix specifying same with respect to the repository root. If DIR is omitted, '.' is assumed.

```
kubectl kustomize DIR [flags]
```

## Examples

```
Build the current working directory
kubectl kustomize

Build some shared configuration directory
kubectl kustomize /home/config/production

Build from github
kubectl kustomize https://github.com/kubernetes-sigs/kustomize.git/examples/helloWorld?
ref=v1.0.6
```

## Options

|                                                                                  |
|----------------------------------------------------------------------------------|
| --as-current-user                                                                |
| use the uid and gid of the command executor to run the function in the container |
| --enable-alpha-plugins                                                           |
| enable kustomize plugins                                                         |
| --enable-helm                                                                    |
| Enable use of the Helm chart inflator generator.                                 |
| -e, --env strings                                                                |
| a list of environment variables to be used by functions                          |

|                                                                                                                                                                   |                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| --helm-command string                                                                                                                                             | Default: "helm"                     |
| helm command (path to executable)                                                                                                                                 |                                     |
| -h, --help                                                                                                                                                        |                                     |
| help for kustomize                                                                                                                                                |                                     |
| --load-restrictor string                                                                                                                                          | Default: "LoadRestrictionsRootOnly" |
| if set to 'LoadRestrictionsNone', local kustomizations may load files from outside their root. This does, however, break the relocatability of the kustomization. |                                     |
| --mount strings                                                                                                                                                   |                                     |
| a list of storage options read from the filesystem                                                                                                                |                                     |
| --network                                                                                                                                                         |                                     |
| enable network access for functions that declare it                                                                                                               |                                     |
| --network-name string                                                                                                                                             | Default: "bridge"                   |
| the docker network to run the container in                                                                                                                        |                                     |
| -o, --output string                                                                                                                                               |                                     |
| If specified, write output to this path.                                                                                                                          |                                     |

|                                                                                                              |                               |
|--------------------------------------------------------------------------------------------------------------|-------------------------------|
| --as string                                                                                                  |                               |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |                               |
| --as-group strings                                                                                           |                               |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |                               |
| --as-uid string                                                                                              |                               |
| UID to impersonate for the operation.                                                                        |                               |

| Default cache directory                                                                                      |                               |
| --certificate-authority string                                                                               |                               |
| Path to a cert file for the certificate authority                                                            |                               |

|                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--client-certificate string</code>                                                                                                                        |
| Path to a client certificate file for TLS                                                                                                                       |
| <code>--client-key string</code>                                                                                                                                |
| Path to a client key file for TLS                                                                                                                               |
| <code>--cloud-provider-gce-l7lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,35.191.0.0/16                                                                    |
| CIDRs opened in GCE firewall for L7 LB traffic proxy & health checks                                                                                            |
| <code>--cloud-provider-gce-lb-src-cidrs cidrs</code> Default: 130.211.0.0/22,209.85.152.0/22,209.85.204.0/22,35.191.0.0/16                                      |
| CIDRs opened in GCE firewall for L4 LB traffic proxy & health checks                                                                                            |
| <code>--cluster string</code>                                                                                                                                   |
| The name of the kubeconfig cluster to use                                                                                                                       |
| <code>--context string</code>                                                                                                                                   |
| The name of the kubeconfig context to use                                                                                                                       |
| <code>--default-not-ready-toleration-seconds int</code> Default: 300                                                                                            |
| Indicates the tolerationSeconds of the toleration for notReady:NoExecute that is added by default to every pod that does not already have such a toleration.    |
| <code>--default-unreachable-toleration-seconds int</code> Default: 300                                                                                          |
| Indicates the tolerationSeconds of the toleration for unreachable:NoExecute that is added by default to every pod that does not already have such a toleration. |
| <code>--disable-compression</code>                                                                                                                              |
| If true, opt-out of response compression for all requests to the server                                                                                         |
| <code>--insecure-skip-tls-verify</code>                                                                                                                         |
| If true, the server's certificate will not be checked for validity. This will make your HTTPS connections insecure                                              |
| <code>--kubeconfig string</code>                                                                                                                                |
| Path to the kubeconfig file to use for CLI requests.                                                                                                            |
| <code>--match-server-version</code>                                                                                                                             |
| Require server version to match client version                                                                                                                  |

|                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -n, --namespace string                                                                                                                                                                            |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| --password string                                                                                                                                                                                 |
| Password for basic authentication to the API server                                                                                                                                               |
| --profile string   Default: "none"                                                                                                                                                                |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| --profile-output string   Default: "profile.pprof"                                                                                                                                                |
| Name of the file to write the profile to                                                                                                                                                          |
| --request-timeout string   Default: "0"                                                                                                                                                           |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| -s, --server string                                                                                                                                                                               |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| --storage-driver-buffer-duration duration   Default: 1m0s                                                                                                                                         |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| --storage-driver-db string   Default: "cadvisor"                                                                                                                                                  |
| database name                                                                                                                                                                                     |
| --storage-driver-host string   Default: "localhost:8086"                                                                                                                                          |
| database host:port                                                                                                                                                                                |
| --storage-driver-password string   Default: "root"                                                                                                                                                |
| database password                                                                                                                                                                                 |
| --storage-driver-secure                                                                                                                                                                           |
| use secure connection with database                                                                                                                                                               |
| --storage-driver-table string   Default: "stats"                                                                                                                                                  |
| table name                                                                                                                                                                                        |
| --storage-driver-user string   Default: "root"                                                                                                                                                    |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |

## See Also

- [kubectl](#) - kubectl controls the Kubernetes cluster manager

# kubectl label

## Synopsis

Update the labels on a resource.

- A label key and value must begin with a letter or number, and may contain letters, numbers, hyphens, dots, and underscores, up to 63 characters each.
- Optionally, the key can begin with a DNS subdomain prefix and a single '/', like example.com/my-app.
- If --overwrite is true, then existing labels can be overwritten, otherwise attempting to overwrite a label will result in an error.
- If --resource-version is specified, then updates will use this resource version, otherwise the existing resource-version will be used.

kubectl label [--overwrite] (-f FILENAME | TYPE NAME) KEY\_1=VAL\_1 ... KEY\_N=VAL\_N [--resource-version=version]

## Examples

```
Update pod 'foo' with the label 'unhealthy' and the value 'true'
kubectl label pods foo unhealthy=true

Update pod 'foo' with the label 'status' and the value 'unhealthy', overwriting any existing value
kubectl label --overwrite pods foo status=unhealthy

Update all pods in the namespace
kubectl label pods --all status=unhealthy

Update a pod identified by the type and name in "pod.json"
kubectl label -f pod.json status=unhealthy

Update pod 'foo' only if the resource is unchanged from version 1
kubectl label pods foo status=unhealthy --resource-version=1

Update pod 'foo' by removing a label named 'bar' if it exists
Does not require the --overwrite flag
kubectl label pods foo bar-
```

|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --all                                              |                                                                                                                                                                                                          |
|                                                    | Select all resources, in the namespace of the specified resource types                                                                                                                                   |
| -A, --all-namespaces                               |                                                                                                                                                                                                          |
|                                                    | If true, check the specified action in all namespaces.                                                                                                                                                   |
| --allow-missing-template-keys    Default: true     |                                                                                                                                                                                                          |
|                                                    | If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats.                                                          |
| --dry-run string[="unchanged"]    Default: "none"  |                                                                                                                                                                                                          |
|                                                    | Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. |
| --field-manager string    Default: "kubectl-label" |                                                                                                                                                                                                          |
|                                                    | Name of the manager used to track field ownership.                                                                                                                                                       |
| --field-selector string                            |                                                                                                                                                                                                          |

|                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Selector (field query) to filter on, supports '=', '==', and '!='.(e.g. --field-selector key1=value1,key2=value2). The server only supports a limited number of field queries per type. |
| -f, --filename strings                                                                                                                                                                  |
| Filename, directory, or URL to files identifying the resource to update the labels                                                                                                      |
| -h, --help                                                                                                                                                                              |
| help for label                                                                                                                                                                          |
| -k, --kustomize string                                                                                                                                                                  |
| Process the kustomization directory. This flag can't be used together with -f or -R.                                                                                                    |
| --list                                                                                                                                                                                  |
| If true, display the labels for a given resource.                                                                                                                                       |
| --local                                                                                                                                                                                 |
| If true, label will NOT contact api-server but run locally.                                                                                                                             |
| -o, --output string                                                                                                                                                                     |
| Output format. One of: (json, yaml, name, go-template, go-template-file, template, templatefile, jsonpath, jsonpath-as-json, jsonpath-file).                                            |
| --overwrite                                                                                                                                                                             |
| If true, allow labels to be overwritten, otherwise reject label updates that overwrite existing labels.                                                                                 |
| -R, --recursive                                                                                                                                                                         |
| Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory.                                         |
| --resource-version string                                                                                                                                                               |
| If non-empty, the labels update will only succeed if this is the current resource-version for the object. Only valid when specifying a single resource.                                 |
| -l, --selector string                                                                                                                                                                   |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. -l key1=value1,key2=value2). Matching objects must satisfy all of the specified label constraints.              |
| --show-managed-fields                                                                                                                                                                   |

|                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                                                                                                             |
| --template string                                                                                                                                                                                                                                         |
| Template string or path to template file to use when -o=go-template, -o=go-template-file. The template format is go lang templates [ <a href="http://golang.org/pkg/text/template/#pkg-overview">http://golang.org/pkg/text/template/#pkg-overview</a> ]. |
| --as string                                                                                                                                                                                                                                               |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace.                                                                                                                                              |
| --as-group strings                                                                                                                                                                                                                                        |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                                                                                                                                                             |
| --as-uid string                                                                                                                                                                                                                                           |
| UID to impersonate for the operation.                                                                                                                                                                                                                     |
| --cache-dir string   Default: "\$HOME/.kube/cache"                                                                                                                                                                                                        |
| Default cache directory                                                                                                                                                                                                                                   |
| --certificate-authority string                                                                                                                                                                                                                            |
| Path to a cert file for the certificate authority                                                                                                                                                                                                         |
| --client-certificate string                                                                                                                                                                                                                               |
| Path to a client certificate file for TLS                                                                                                                                                                                                                 |
| --client-key string                                                                                                                                                                                                                                       |
| Path to a client key file for TLS                                                                                                                                                                                                                         |

# kubectl logs

## Synopsis

Print the logs for a container in a pod or specified resource. If the pod has only one container, the container name is optional.

```
kubectl logs [-f] [-p] (POD | TYPE/NAME) [-c CONTAINER]
```

## Examples

```
Return snapshot logs from pod nginx with only one container
kubectl logs nginx
```

```
Return snapshot logs from pod nginx with multi containers
kubectl logs nginx --all-containers=true
```

```
Return snapshot logs from all containers in pods defined by label app=nginx
kubectl logs -l app=nginx --all-containers=true
```

```
Return snapshot of previous terminated ruby container logs from pod web-1
kubectl logs -p -c ruby web-1
```

```
Begin streaming the logs of the ruby container in pod web-1
kubectl logs -f -c ruby web-1
```

```
Begin streaming the logs from all containers in pods defined by label app=nginx
kubectl logs -f -l app=nginx --all-containers=true
```

```
Display only the most recent 20 lines of output in pod nginx
kubectl logs --tail=20 nginx
```

```
Show all logs from pod nginx written in the last hour
kubectl logs --since=1h nginx
```

```
Show logs from a kubelet with an expired serving certificate
kubectl logs --insecure-skip-tls-verify-backend nginx
```

```
Return snapshot logs from first container of a job named hello
kubectl logs job/hello
```

```
Return snapshot logs from container nginx-1 of a deployment named nginx
kubectl logs deployment/nginx -c nginx-1
```

## Options

|                                    |                                                                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --all-containers                   |                                                                                                                                                                                                                       |
|                                    | Get all containers' logs in the pod(s).                                                                                                                                                                               |
| -c, --container string             |                                                                                                                                                                                                                       |
|                                    | Print the logs of this container                                                                                                                                                                                      |
| -f, --follow                       |                                                                                                                                                                                                                       |
|                                    | Specify if the logs should be streamed.                                                                                                                                                                               |
| -h, --help                         |                                                                                                                                                                                                                       |
|                                    | help for logs                                                                                                                                                                                                         |
| --ignore-errors                    |                                                                                                                                                                                                                       |
|                                    | If watching / following pod logs, allow for any errors that occur to be non-fatal                                                                                                                                     |
| --insecure-skip-tls-verify-backend |                                                                                                                                                                                                                       |
|                                    | Skip verifying the identity of the kubelet that logs are requested from. In theory, an attacker could provide invalid log content back. You might want to use this if your kubelet serving certificates have expired. |
| --limit-bytes int                  |                                                                                                                                                                                                                       |
|                                    | Maximum bytes of logs to return. Defaults to no limit.                                                                                                                                                                |
| --max-log-requests int             | Default: 5                                                                                                                                                                                                            |
|                                    | Specify maximum number of concurrent logs to follow when using by a selector. Defaults to 5.                                                                                                                          |
| --pod-running-timeout duration     | Default: 20s                                                                                                                                                                                                          |
|                                    | The length of time (like 5s, 2m, or 3h, higher than zero) to wait until at least one pod is running                                                                                                                   |
| --prefix                           |                                                                                                                                                                                                                       |

|                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Prefix each log line with the log source (pod name and container name)                                                                                                                   |
| <code>-p, --previous</code>                                                                                                                                                              |
| If true, print the logs for the previous instance of the container in a pod if it exists.                                                                                                |
| <code>-l, --selector string</code>                                                                                                                                                       |
| Selector (label query) to filter on, supports '=', '==', and '!='.(e.g. <code>-l key1=value1,key2=value2</code> ). Matching objects must satisfy all of the specified label constraints. |
| <code>--since duration</code>                                                                                                                                                            |
| Only return logs newer than a relative duration like 5s, 2m, or 3h. Defaults to all logs. Only one of since-time / since may be used.                                                    |
| <code>--since-time string</code>                                                                                                                                                         |
| Only return logs after a specific date (RFC3339). Defaults to all logs. Only one of since-time / since may be used.                                                                      |
| <code>--tail int</code> Default: -1                                                                                                                                                      |
| Lines of recent log file to display. Defaults to -1 with no selector, showing all log lines otherwise 10, if a selector is provided.                                                     |
| <code>--timestamps</code>                                                                                                                                                                |
| Include timestamps on each line in the log output                                                                                                                                        |

|                                                                                                              |
|--------------------------------------------------------------------------------------------------------------|
| <code>--as string</code>                                                                                     |
| Username to impersonate for the operation. User could be a regular user or a service account in a namespace. |
| <code>--as-group strings</code>                                                                              |
| Group to impersonate for the operation, this flag can be repeated to specify multiple groups.                |
| <code>--as-uid string</code>                                                                                 |
| UID to impersonate for the operation.                                                                        |
| <code>--cache-dir string</code> Default: "\$HOME/.kube/cache"                                                |
| Default cache directory                                                                                      |
| <code>--certificate-authority string</code>                                                                  |

| Require server version to match client version                                                                                                                                                    |
| <code>-n, --namespace string</code>                                                                                                                                                               |
| If present, the namespace scope for this CLI request                                                                                                                                              |
| <code>--password string</code>                                                                                                                                                                    |
| Password for basic authentication to the API server                                                                                                                                               |
| <code>--profile string</code> Default: "none"                                                                                                                                                     |
| Name of profile to capture. One of (none cpu heap goroutine threadcreate block mutex)                                                                                                             |
| <code>--profile-output string</code> Default: "profile.pprof"                                                                                                                                     |
| Name of the file to write the profile to                                                                                                                                                          |
| <code>--request-timeout string</code> Default: "0"                                                                                                                                                |
| The length of time to wait before giving up on a single server request. Non-zero values should contain a corresponding time unit (e.g. 1s, 2m, 3h). A value of zero means don't timeout requests. |
| <code>-s, --server string</code>                                                                                                                                                                  |
| The address and port of the Kubernetes API server                                                                                                                                                 |
| <code>--storage-driver-buffer-duration duration</code> Default: 1m0s                                                                                                                              |
| Writes in the storage driver will be buffered for this duration, and committed to the non memory backends as a single transaction                                                                 |
| <code>--storage-driver-db string</code> Default: "cadvisor"                                                                                                                                       |
| database name                                                                                                                                                                                     |
| <code>--storage-driver-host string</code> Default: "localhost:8086"                                                                                                                               |
| database host:port                                                                                                                                                                                |
| <code>--storage-driver-password string</code> Default: "root"                                                                                                                                     |
| database password                                                                                                                                                                                 |
| <code>--storage-driver-secure</code>                                                                                                                                                              |
| use secure connection with database                                                                                                                                                               |
| <code>--storage-driver-table string</code> Default: "stats"                                                                                                                                       |

|                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------|
| table name                                                                                                                   |
| --storage-driver-user string    Default: "root"                                                                              |
| database username                                                                                                            |
| --tls-server-name string                                                                                                     |
| Server name to use for server certificate validation. If it is not provided, the hostname used to contact the server is used |
| --token string                                                                                                               |
| Bearer token for authentication to the API server                                                                            |
| --user string                                                                                                                |
| The name of the kubeconfig user to use                                                                                       |
| --username string                                                                                                            |
| Username for basic authentication to the API server                                                                          |
| --version version[=true]                                                                                                     |
| --version, --version=raw prints version information and quits; --version=vX.Y.Z... sets the reported version                 |
| --warnings-as-errors                                                                                                         |
| Treat warnings received from the server as errors and exit with a non-zero exit code                                         |
