Return data at any resource version. The newest available resource version is preferred, but strong consistency is not required; data at any resource version may be served. It is possible for the request to return data at a much older resource version that the client has previously observed, particularly in high availability configurations, due to partitions or stale caches. Clients that cannot tolerate this should not use this semantic.

Most recent

Return data at the most recent resource version. The returned data must be consistent (in detail: served from etcd via a quorum read).

Not older than

Return data at least as new as the provided `resourceVersion`. The newest available data is preferred, but any data not older than the provided `resourceVersion` may be served. For **list** requests to servers that honor the `resourceVersionMatch` parameter, this guarantees that the collection's `.metadata.resourceVersion` is not older than the requested `resourceVersion`, but does not make any guarantee about the `.metadata.resourceVersion` of any of the items in that collection.

Exact

Return data at the exact resource version provided. If the provided `resourceVersion` is unavailable, the server responds with HTTP 410 "Gone". For **list** requests to servers that honor the `resourceVersionMatch` parameter, this guarantees that the collection's `.metadata.resourceVersion` is the same as the `resourceVersion` you requested in the query string. That guarantee does not apply to the `.metadata.resourceVersion` of any items within that collection.

Continue Token, Exact

Return data at the resource version of the initial paginated **list** call. The returned *continue tokens* are responsible for keeping track of the initially provided resource version for all paginated **list** calls after the initial paginated **list**.

**Note:**

When you **list** resources and receive a collection response, the response includes the [list metadata](#) of the collection as well as [object metadata](#) for each item in that collection. For individual objects found within a collection response, `.metadata.resourceVersion` tracks when that object was last updated, and not how up-to-date the object is when served.

When using `resourceVersionMatch=NotOlderThan` and `limit` is set, clients must handle HTTP 410 "Gone" responses. For example, the client might retry with a newer `resourceVersion` or fall back to `resourceVersion=""`.

When using `resourceVersionMatch=Exact` and `limit` is unset, clients must verify that the collection's `.metadata.resourceVersion` matches the requested `resourceVersion`, and handle the case where it does not. For example, the client might fall back to a request with `limit` set.

## Semantics for watch

For **watch**, the semantics of resource version are:

### watch:

resourceVersion for watch

| resourceVersion unset              | resourceVersion="0"        | resourceVersion="{value other than 0}" |
|------------------------------------|----------------------------|----------------------------------------|
| Get State and Start at Most Recent | Get State and Start at Any | Start at Exact                         |

The meaning of those **watch** semantics are:

Get State and Start at Any

### Caution:

Watches initialized this way may return arbitrarily stale data. Please review this semantic before using it, and favor the other semantics where possible.

Start a **watch** at any resource version; the most recent resource version available is preferred, but not required. Any starting resource version is allowed. It is possible for the **watch** to start at a much older resource version that the client has previously observed, particularly in high availability configurations, due to partitions or stale caches. Clients that cannot tolerate this apparent rewinding should not start a **watch** with this semantic. To establish initial state, the **watch** begins with synthetic "Added" events for all resource instances that exist at the starting resource version. All following watch events are for all changes that occurred after the resource version the **watch** started at.

Get State and Start at Most Recent

Start a **watch** at the most recent resource version, which must be consistent (in detail: served from etcd via a quorum read). To establish initial state, the **watch** begins with synthetic "Added" events of all resources instances that exist at the starting resource version. All following watch events are for all changes that occurred after the resource version the **watch** started at.

Start at Exact

Start a **watch** at an exact resource version. The watch events are for all changes after the provided resource version. Unlike "Get State and Start at Most Recent" and "Get State and Start at Any", the **watch** is not started with synthetic "Added" events for the provided resource version. The client is assumed to already have the initial state at the starting resource version since the client provided the resource version.

## "410 Gone" responses

Servers are not required to serve all older resource versions and may return a HTTP 410 (Gone) status code if a client requests a `resourceVersion` older than the server has retained. Clients must be able to tolerate 410 (Gone) responses. See [Efficient detection of changes](#) for details on how to handle 410 (Gone) responses when watching resources.

If you request a resourceVersion outside the applicable limit then, depending on whether a request is served from cache or not, the API server may reply with a 410 Gone HTTP response.

## Unavailable resource versions

Servers are not required to serve unrecognized resource versions. If you request **list** or **get** for a resource version that the API server does not recognize, then the API server may either:

- wait briefly for the resource version to become available, then timeout with a 504 (Gateway Timeout) if the provided resource versions does not become available in a reasonable amount of time;
- respond with a Retry-After response header indicating how many seconds a client should wait before retrying the request.

If you request a resource version that an API server does not recognize, the kube-apiserver additionally identifies its error responses with a "Too large resource version" message.

If you make a **watch** request for an unrecognized resource version, the API server may wait indefinitely (until the request timeout) for the resource version to become available.

# Server-Side Apply

FEATURE STATE: Kubernetes v1.22 [stable]

Kubernetes supports multiple appliers collaborating to manage the fields of a single [object](#).

Server-Side Apply provides an optional mechanism for your cluster's control plane to track changes to an object's fields. At the level of a specific resource, Server-Side Apply records and tracks information about control over the fields of that object.

Server-Side Apply helps users and [controllers](#) manage their resources through declarative configuration. Clients can create and modify [objects](#) declaratively by submitting their *fully specified intent*.

A fully specified intent is a partial object that only includes the fields and values for which the user has an opinion. That intent either creates a new object (using default values for unspecified fields), or is [combined](#), by the API server, with the existing object.

[Comparison with Client-Side Apply](#) explains how Server-Side Apply differs from the original, client-side kubectl apply implementation.

## Field management

The Kubernetes API server tracks *managed fields* for all newly created objects.

When trying to apply an object, fields that have a different value and are owned by another [manager](#) will result in a [conflict](#). This is done in order to signal that the operation might undo another collaborator's changes. Writes to objects with managed fields can be forced, in which case the value of any conflicted field will be overridden, and the ownership will be transferred.

Whenever a field's value does change, ownership moves from its current manager to the manager making the change.

Apply checks if there are any other field managers that also own the field. If the field is not owned by any other field managers, that field is set to its default value (if there is one), or otherwise is deleted from the object. The same rule applies to fields that are lists, associative lists, or maps.

For a user to manage a field, in the Server-Side Apply sense, means that the user relies on and expects the value of the field not to change. The user who last made an assertion about the value of a field will be recorded as the current field manager. This can be done by changing the field manager details explicitly using HTTP POST (**create**), PUT (**update**), or non-apply PATCH (**patch**). You can also declare and record a field manager by including a value for that field in a Server-Side Apply operation.

A Server-Side Apply **patch** request requires the client to provide its identity as a [field manager](#). When using Server-Side Apply, trying to change a field that is controlled by a different manager results in a rejected request unless the client forces an override. For details of overrides, see [Conflicts](#).

When two or more appliers set a field to the same value, they share ownership of that field. Any subsequent attempt to change the value of the shared field, by any of the appliers, results in a conflict. Shared field owners may give up ownership of a field by making a Server-Side Apply **patch** request that doesn't include that field.

Field management details are stored in a `managedFields` field that is part of an object's [metadata](#).

If you remove a field from a manifest and apply that manifest, Server-Side Apply checks if there are any other field managers that also own the field. If the field is not owned by any other field managers, it is either deleted from the live object or reset to its default value, if it has one. The same rule applies to associative list or map items.

Compared to the (legacy) [kubectrl.kubernetes.io/last-applied-configuration](https://kubernetes.io/docs/concepts/configuration/last-applied-configuration/) annotation managed by kubectrl, Server-Side Apply uses a more declarative approach, that tracks a user's (or client's) field management, rather than a user's last applied state. As a side effect of using Server-Side Apply, information about which field manager manages each field in an object also becomes available.

## Example

A simple example of an object created using Server-Side Apply could look like this:

```

apiVersion: v1
kind: ConfigMap
metadata:
 name: test-cm
 namespace: default
 labels:
 test-label: test
 managedFields:
 - manager: kubectrl
 operation: Apply # note capitalization: "Apply" (or "Update")
 apiVersion: v1
 time: "2010-10-10T0:00:00Z"
```

```
fieldsType: FieldsV1
fieldsV1:
 f:metadata:
 f:labels:
 f:test-label: {}
 f:data:
 f:key: {}
data:
 key: some value
```

That example ConfigMap object contains a single field management record in `.metadata.managedFields`. The field management record consists of basic information about the managing entity itself, plus details about the fields being managed and the relevant operation (Apply or Update). If the request that last changed that field was a Server-Side Apply **patch** then the value of operation is Apply; otherwise, it is Update.

There is another possible outcome. A client could submit an invalid request body. If the fully specified intent does not produce a valid object, the request fails.

It is however possible to change `.metadata.managedFields` through an **update**, or through a **patch** operation that does not use Server-Side Apply. Doing so is highly discouraged, but might be a reasonable option to try if, for example, the `.metadata.managedFields` get into an inconsistent state (which should not happen in normal operations).

The format of managedFields is [described](#) in the Kubernetes API reference.

### Caution:

The `.metadata.managedFields` field is managed by the API server. You should avoid updating it manually.

## Conflicts

A *conflict* is a special status error that occurs when an Apply operation tries to change a field that another manager also claims to manage. This prevents an applier from unintentionally overwriting the value set by another user. When this occurs, the applier has 3 options to resolve the conflicts:

- **Overwrite value, become sole manager:** If overwriting the value was intentional (or if the applier is an automated process like a controller) the applier should set the force query parameter to true (for kubectl apply, you use the `--force-conflicts` command line parameter), and make the request again. This forces the operation to succeed, changes the value of the field, and removes the field from all other managers' entries in managedFields.
- **Don't overwrite value, give up management claim:** If the applier doesn't care about the value of the field any more, the applier can remove it from their local model of the resource, and make a new request with that particular field omitted. This leaves the value unchanged, and causes the field to be removed from the applier's entry in managedFields.
- **Don't overwrite value, become shared manager:** If the applier still cares about the value of a field, but doesn't want to overwrite it, they can change the value of that field in their local model of the resource so as to match the value of the object on the server, and

then make a new request that takes into account that local update. Doing so leaves the value unchanged, and causes that field's management to be shared by the applier along with all other field managers that already claimed to manage it.

## Field managers

Managers identify distinct workflows that are modifying the object (especially useful on conflicts!), and can be specified through the [fieldManager](#) query parameter as part of a modifying request. When you Apply to a resource, the `fieldManager` parameter is required. For other updates, the API server infers a field manager identity from the "User-Agent:" HTTP header (if present).

When you use the `kubectl` tool to perform a Server-Side Apply operation, `kubectl` sets the manager identity to "kubectl" by default.

## Serialization

At the protocol level, Kubernetes represents Server-Side Apply message bodies as [YAML](#), with the media type `application/apply-patch+yaml`.

### Note:

Whether you are submitting JSON data or YAML data, use `application/apply-patch+yaml` as the Content-Type header value.

All JSON documents are valid YAML. However, Kubernetes has a bug where it uses a YAML parser that does not fully implement the YAML specification. Some JSON escapes may not be recognized.

The serialization is the same as for Kubernetes objects, with the exception that clients are not required to send a complete object.

Here's an example of a Server-Side Apply message body (fully specified intent):

```
{
 "apiVersion": "v1",
 "kind": "ConfigMap"
}
```

(this would make a no-change update, provided that it was sent as the body of a **patch** request to a valid `v1/configmaps` resource, and with the appropriate request Content-Type).

## Operations in scope for field management

The Kubernetes API operations where field management is considered are:

1. Server-Side Apply (HTTP PATCH, with content type `application/apply-patch+yaml`)
2. Replacing an existing object (**update** to Kubernetes; PUT at the HTTP level)

Both operations update `.metadata.managedFields`, but behave a little differently.

Unless you specify a forced override, an apply operation that encounters field-level conflicts always fails; by contrast, if you make a change using **update** that would affect a managed field, a conflict never provokes failure of the operation.

All Server-Side Apply **patch** requests are required to identify themselves by providing a `fieldManager` query parameter, while the query parameter is optional for **update** operations. Finally, when using the Apply operation you cannot define `managedFields` in the body of the request that you submit.

An example object with multiple managers could look like this:

```

apiVersion: v1
kind: ConfigMap
metadata:
 name: test-cm
 namespace: default
 labels:
 test-label: test
 managedFields:
 - manager: kubectl
 operation: Apply
 apiVersion: v1
 fields:
 f:metadata:
 f:labels:
 f:test-label: {}
 - manager: kube-controller-manager
 operation: Update
 apiVersion: v1
 time: '2019-03-30T16:00:00.000Z'
 fields:
 f:data:
 f:key: {}
data:
 key: new value
```

In this example, a second operation was run as an **update** by the manager called `kube-controller-manager`. The update request succeeded and changed a value in the `data` field, which caused that field's management to change to the `kube-controller-manager`.

If this update has instead been attempted using Server-Side Apply, the request would have failed due to conflicting ownership.

## Merge strategy

The merging strategy, implemented with Server-Side Apply, provides a generally more stable object lifecycle. Server-Side Apply tries to merge fields based on the actor who manages them instead of overruling based on values. This way multiple actors can update the same object without causing unexpected interference.

When a user sends a *fully-specified intent* object to the Server-Side Apply endpoint, the server merges it with the live object favoring the value from the request body if it is specified in both

places. If the set of items present in the applied config is not a superset of the items applied by the same user last time, each missing item not managed by any other appliers is removed. For more information about how an object's schema is used to make decisions when merging, see [sigs.k8s.io/structured-merge-diff](https://sigs.k8s.io/structured-merge-diff).

The Kubernetes API (and the Go code that implements that API for Kubernetes) allows defining *merge strategy markers*. These markers describe the merge strategy supported for fields within Kubernetes objects. For a [CustomResourceDefinition](#), you can set these markers when you define the custom resource.

| Golang marker | OpenAPI extension          | Possible values                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| //+listType   | x-kubernetes-list-type     | atomic/set/map                                 | Applicable to lists. set applies to lists that include only scalar elements. These elements must be unique. map applies to lists of nested types only. The key values (see listMapKey) must be unique in the list. atomic can apply to any list. If configured as atomic, the entire list is replaced during merge. At any point in time, a single manager owns the list. If set or map, different managers can manage entries separately. |
| //+listMapKey | x-kubernetes-list-map-keys | List of field names, e.g. ["port", "protocol"] | Only applicable when +listType=map. A list of field names whose values uniquely identify entries in the list. While there can be multiple keys, listMapKey is singular because keys need to be specified individually in the Go type. The key fields must be scalars.                                                                                                                                                                      |
| //+mapType    | x-kubernetes-map-type      | atomic/granular                                | Applicable to maps. atomic means that the map can only be entirely replaced by a single manager. granular means that the map supports separate managers updating individual fields.                                                                                                                                                                                                                                                        |
| //+structType | x-kubernetes-map-type      | atomic/granular                                | Applicable to structs; otherwise same usage and OpenAPI annotation as //+mapType.                                                                                                                                                                                                                                                                                                                                                          |

If listType is missing, the API server interprets a patchStrategy=merge marker as a listType=map and the corresponding patchMergeKey marker as a listMapKey.

The atomic list type is recursive.

(In the [Go](#) code for Kubernetes, these markers are specified as comments and code authors need not repeat them as field tags).

## Custom resources and Server-Side Apply

By default, Server-Side Apply treats custom resources as unstructured data. All keys are treated the same as struct fields, and all lists are considered atomic.

If the CustomResourceDefinition defines a [schema](#) that contains annotations as defined in the previous [Merge Strategy](#) section, these annotations will be used when merging objects of this type.

## Compatibility across topology changes

On rare occurrences, the author for a CustomResourceDefinition (CRD) or built-in may want to change the specific topology of a field in their resource, without incrementing its API version. Changing the topology of types, by upgrading the cluster or updating the CRD, has different consequences when updating existing objects. There are two categories of changes: when a field goes from map/set/granular to atomic, and the other way around.

When the listType, mapType, or structType changes from map/set/granular to atomic, the whole list, map, or struct of existing objects will end-up being owned by actors who owned an element of these types. This means that any further change to these objects would cause a conflict.

When a listType, mapType, or structType changes from atomic to map/set/granular, the API server is unable to infer the new ownership of these fields. Because of that, no conflict will be produced when objects have these fields updated. For that reason, it is not recommended to change a type from atomic to map/set/granular.

Take for example, the custom resource:

```

apiVersion: example.com/v1
kind: Foo
metadata:
 name: foo-sample
 managedFields:
 - manager: "manager-one"
 operation: Apply
 apiVersion: example.com/v1
 fields:
 f:spec:
 f:data: {}
spec:
 data:
 key1: val1
 key2: val2
```

Before spec.data gets changed from atomic to granular, manager-one owns the field spec.data, and all the fields within it (key1 and key2). When the CRD gets changed to make spec.data granular, manager-one continues to own the top-level field spec.data (meaning no other managers can delete the map called data without a conflict), but it no longer owns key1 and key2, so another manager can then modify or delete those fields without conflict.

## Using Server-Side Apply in a controller

As a developer of a controller, you can use Server-Side Apply as a way to simplify the update logic of your controller. The main differences with a read-modify-write and/or patch are the following:

- the applied object must contain all the fields that the controller cares about.
- there is no way to remove fields that haven't been applied by the controller before (controller can still send a **patch** or **update** for these use-cases).

- the object doesn't have to be read beforehand; resourceVersion doesn't have to be specified.

It is strongly recommended for controllers to always force conflicts on objects that they own and manage, since they might not be able to resolve or act on these conflicts.

## Transferring ownership

In addition to the concurrency controls provided by [conflict resolution](#), Server-Side Apply provides ways to perform coordinated field ownership transfers from users to controllers.

This is best explained by example. Let's look at how to safely transfer ownership of the replicas field from a user to a controller while enabling automatic horizontal scaling for a Deployment, using the HorizontalPodAutoscaler resource and its accompanying controller.

Say a user has defined Deployment with replicas set to the desired value:

[application/ssa/nginx-deployment.yaml](#)

```
apiVersion: apps/v1
kind: Deployment
metadata:
 name: nginx-deployment
 labels:
 app: nginx
spec:
 replicas: 3
 selector:
 matchLabels:
 app: nginx
 template:
 metadata:
 labels:
 app: nginx
 spec:
 containers:
 - name: nginx
 image: nginx:1.14.2
```

And the user has created the Deployment using Server-Side Apply, like so:

```
kubectl apply -f https://k8s.io/examples/application/ssa/nginx-deployment.yaml --server-side
```

Then later, automatic scaling is enabled for the Deployment; for example:

```
kubectl autoscale deployment nginx-deployment --cpu-percent=50 --min=1 --max=10
```

Now, the user would like to remove replicas from their configuration, so they don't accidentally fight with the HorizontalPodAutoscaler (HPA) and its controller. However, there is a race: it might take some time before the HPA feels the need to adjust .spec.replicas; if the user removes .spec.replicas before the HPA writes to the field and becomes its owner, then the API server would set .spec.replicas to 1 (the default replica count for Deployment). This is not what the user wants to happen, even temporarily - it might well degrade a running workload.

There are two solutions:

- (basic) Leave replicas in the configuration; when the HPA eventually writes to that field, the system gives the user a conflict over it. At that point, it is safe to remove from the configuration.
- (more advanced) If, however, the user doesn't want to wait, for example because they want to keep the cluster legible to their colleagues, then they can take the following steps to make it safe to remove replicas from their configuration:

First, the user defines a new manifest containing only the replicas field:

```
Save this file as 'nginx-deployment-replicas-only.yaml'.
apiVersion: apps/v1
kind: Deployment
metadata:
 name: nginx-deployment
spec:
 replicas: 3
```

**Note:**

The YAML file for SSA in this case only contains the fields you want to change. You are not supposed to provide a fully compliant Deployment manifest if you only want to modify the spec.replicas field using SSA.

The user applies that manifest using a private field manager name. In this example, the user picked handover-to-hpa:

```
kubectl apply -f nginx-deployment-replicas-only.yaml \
--server-side --field-manager=handover-to-hpa \
--validate=false
```

If the apply results in a conflict with the HPA controller, then do nothing. The conflict indicates the controller has claimed the field earlier in the process than it sometimes does.

At this point the user may remove the replicas field from their manifest:

[application/ssa/nginx-deployment-no-replicas.yaml](#)

```
apiVersion: apps/v1
kind: Deployment
metadata:
 name: nginx-deployment
labels:
 app: nginx
spec:
 selector:
 matchLabels:
 app: nginx
 template:
 metadata:
 labels:
 app: nginx
```

```
spec:
 containers:
 - name: nginx
 image: nginx:1.14.2
```

Note that whenever the HPA controller sets the `replicas` field to a new value, the temporary field manager will no longer own any fields and will be automatically deleted. No further clean up is required.

## Transferring ownership between managers

Field managers can transfer ownership of a field between each other by setting the field to the same value in both of their applied configurations, causing them to share ownership of the field. Once the managers share ownership of the field, one of them can remove the field from their applied configuration to give up ownership and complete the transfer to the other field manager.

## Comparison with Client-Side Apply

Server-Side Apply is meant both as a replacement for the original client-side implementation of the `kubectl apply` subcommand, and as simple and effective mechanism for [controllers](#) to enact their changes.

Compared to the last-applied annotation managed by `kubectl`, Server-Side Apply uses a more declarative approach, which tracks an object's field management, rather than a user's last applied state. This means that as a side effect of using Server-Side Apply, information about which field manager manages each field in an object also becomes available.

A consequence of the conflict detection and resolution implemented by Server-Side Apply is that an applier always has up to date field values in their local state. If they don't, they get a conflict the next time they apply. Any of the three options to resolve conflicts results in the applied configuration being an up to date subset of the object on the server's fields.

This is different from Client-Side Apply, where outdated values which have been overwritten by other users are left in an applier's local config. These values only become accurate when the user updates that specific field, if ever, and an applier has no way of knowing whether their next apply will overwrite other users' changes.

Another difference is that an applier using Client-Side Apply is unable to change the API version they are using, but Server-Side Apply supports this use case.

## Migration between client-side and server-side apply

### Upgrading from client-side apply to server-side apply

Client-side apply users who manage a resource with `kubectl apply` can start using server-side apply with the following flag.

```
kubectl apply --server-side [--dry-run=server]
```

By default, field management of the object transfers from client-side apply to `kubectl server-side apply`, without encountering conflicts.

## Caution:

Keep the `last-applied-configuration` annotation up to date. The annotation infers client-side applies managed fields. Any fields not managed by client-side apply raise conflicts.

For example, if you used `kubectl scale` to update the `replicas` field after client-side apply, then this field is not owned by client-side apply and creates conflicts on `kubectl apply --server-side`.

This behavior applies to server-side apply with the `kubectl` field manager. As an exception, you can opt-out of this behavior by specifying a different, non-default field manager, as seen in the following example. The default field manager for `kubectl` server-side apply is `kubectl`.

```
kubectl apply --server-side --field-manager=my-manager [--dry-run=server]
```

## Downgrading from server-side apply to client-side apply

If you manage a resource with `kubectl apply --server-side`, you can downgrade to client-side apply directly with `kubectl apply`.

Downgrading works because `kubectl` Server-Side Apply keeps the `last-applied-configuration` annotation up-to-date if you use `kubectl apply`.

This behavior applies to Server-Side Apply with the `kubectl` field manager. As an exception, you can opt-out of this behavior by specifying a different, non-default field manager, as seen in the following example. The default field manager for `kubectl` server-side apply is `kubectl`.

```
kubectl apply --server-side --field-manager=my-manager [--dry-run=server]
```

## API implementation

The `PATCH` verb for a resource that supports Server-Side Apply can accept the unofficial `application/apply-patch+yaml` content type. Users of Server-Side Apply can send partially specified objects as YAML as the body of a `PATCH` request to the URI of a resource. When applying a configuration, you should always include all the fields that are important to the outcome (such as a desired state) that you want to define.

All JSON messages are valid YAML. Some clients specify Server-Side Apply requests using YAML request bodies that are also valid JSON.

## Access control and permissions

Since Server-Side Apply is a type of `PATCH`, a principal (such as a Role for Kubernetes [RBAC](#)) requires the **patch** permission to edit existing resources, and also needs the **create** verb permission in order to create new resources with Server-Side Apply.

## Clearing managedFields

It is possible to strip all `managedFields` from an object by overwriting them using a **patch** (JSON Merge Patch, Strategic Merge Patch, JSON Patch), or through an **update** (HTTP PUT); in other words, through every write operation other than **apply**. This can be done by overwriting the `managedFields` field with an empty entry. Two examples are:

```
PATCH /api/v1/namespaces/default/configmaps/example-cm
Accept: application/json
Content-Type: application/merge-patch+json
```

```
{
 "metadata": {
 "managedFields": [
 {}
]
 }
}
```

```
PATCH /api/v1/namespaces/default/configmaps/example-cm
Accept: application/json
Content-Type: application/json-patch+json
If-Match: 1234567890123456789
```

```
[{"op": "replace", "path": "/metadata/managedFields", "value": [{}]}]
```

This will overwrite the managedFields with a list containing a single empty entry that then results in the managedFields being stripped entirely from the object. Note that setting the managedFields to an empty list will not reset the field. This is on purpose, so managedFields never get stripped by clients not aware of the field.

In cases where the reset operation is combined with changes to other fields than the managedFields, this will result in the managedFields being reset first and the other changes being processed afterwards. As a result the applier takes ownership of any fields updated in the same request.

#### **Note:**

Server-Side Apply does not correctly track ownership on sub-resources that don't receive the resource object type. If you are using Server-Side Apply with such a sub-resource, the changed fields may not be tracked.

## **What's next**

You can read about managedFields within the Kubernetes API reference for the [metadata](#) top level field.

## **Client Libraries**

This page contains an overview of the client libraries for using the Kubernetes API from various programming languages.

To write applications using the [Kubernetes REST API](#), you do not need to implement the API calls and request/response types yourself. You can use a client library for the programming language you are using.

Client libraries often handle common tasks such as authentication for you. Most client libraries can discover and use the Kubernetes Service Account to authenticate if the API client is

running inside the Kubernetes cluster, or can understand the [kubeconfig file](#) format to read the credentials and the API Server address.

## Officially-supported Kubernetes client libraries

The following client libraries are officially maintained by [Kubernetes SIG API Machinery](#).

| Language   | Client Library                                                                                        | Sample Programs        |
|------------|-------------------------------------------------------------------------------------------------------|------------------------|
| C          | <a href="https://github.com/kubernetes-client/c">github.com/kubernetes-client/c</a>                   | <a href="#">browse</a> |
| dotnet     | <a href="https://github.com/kubernetes-client/csharp">github.com/kubernetes-client/csharp</a>         | <a href="#">browse</a> |
| Go         | <a href="https://github.com/kubernetes/client-go/">github.com/kubernetes/client-go/</a>               | <a href="#">browse</a> |
| Haskell    | <a href="https://github.com/kubernetes-client/haskell">github.com/kubernetes-client/haskell</a>       | <a href="#">browse</a> |

# Common Expression Language in Kubernetes

The [Common Expression Language \(CEL\)](#) is used in the Kubernetes API to declare validation rules, policy rules, and other constraints or conditions.

CEL expressions are evaluated directly in the [API server](#), making CEL a convenient alternative to out-of-process mechanisms, such as webhooks, for many extensibility use cases. Your CEL expressions continue to execute so long as the control plane's API server component remains available.

## Language overview

The [CEL language](#) has a straightforward syntax that is similar to the expressions in C, C++, Java, JavaScript and Go.

CEL was designed to be embedded into applications. Each CEL "program" is a single expression that evaluates to a single value. CEL expressions are typically short "one-liners" that inline well into the string fields of Kubernetes API resources.

Inputs to a CEL program are "variables". Each Kubernetes API field that contains CEL declares in the API documentation which variables are available to use for that field. For example, in the `x-kubernetes-validations[i].rules` field of CustomResourceDefinitions, the `self` and `oldSelf` variables are available and refer to the previous and current state of the custom resource data to be validated by the CEL expression. Other Kubernetes API fields may declare different variables. See the API documentation of the API fields to learn which variables are available for that field.

Example CEL expressions:

Examples of CEL expressions and the purpose of each

| Rule                                                                                                  | Purpose                                                                           |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>self.minReplicas &lt;= self.replicas &amp;&amp; self.replicas &lt;= self.maxReplicas</code>     | Validate that the three fields defining replicas are ordered appropriately        |
| <code>'Available' in self.stateCounts</code>                                                          | Validate that an entry with the 'Available' key exists in a map                   |
| <code>(self.list1.size() == 0) != (self.list2.size() == 0)</code>                                     | Validate that one of two lists is non-empty, but not both                         |
| <code>self.envvars.filter(e, e.name == 'MY_ENV').all(e, e.value.matches('[a-zA-Z]*\$'))</code>        | Validate the 'value' field of a listMap entry where key field 'name' is 'MY_ENV'  |
| <code>has(self.expired) &amp;&amp; self.created + self.ttl &lt; self.expired</code>                   | Validate that 'expired' date is after a 'create' date plus a 'ttl' duration       |
| <code>self.health.startsWith('ok')</code>                                                             | Validate a 'health' string field has the prefix 'ok'                              |
| <code>self.widgets.exists(w, w.key == 'x' &amp;&amp; w.foo &lt; 10)</code>                            | Validate that the 'foo' property of a listMap item with a key 'x' is less than 10 |
| <code>type(self) == string ? self == '99%' : self == 42</code>                                        | Validate an int-or-string field for both the int and string cases                 |
| <code>self.metadata.name == 'singleton'</code>                                                        | Validate that an object's name matches a specific value (making it a singleton)   |
| <code>self.set1.all(e, !(e in self.set2))</code>                                                      | Validate that two listSets are disjoint                                           |
| <code>self.names.size() == self.details.size() &amp;&amp; self.names.all(n, n in self.details)</code> | Validate the 'details' map is keyed by the items in the 'names' listSet           |
| <code>self.details.all(key, key.matches('[a-zA-Z]*\$'))</code>                                        | Validate the keys of the 'details' map                                            |
| <code>self.details.all(key, self.details[key].matches('[a-zA-Z]*\$'))</code>                          | Validate the values of the 'details' map                                          |

## CEL options, language features, and libraries

CEL is configured with the following options, libraries and language features, introduced at the specified Kubernetes versions:

| CEL option, library or language feature        | Included                                                                                                                     |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">Standard macros</a>                | <code>has</code> , <code>all</code> , <code>exists</code> , <code>exists_one</code> , <code>map</code> , <code>filter</code> |
| <a href="#">Standard functions</a>             | See <a href="#">official list of standard definitions</a>                                                                    |
| <a href="#">Homogeneous Aggregate Literals</a> |                                                                                                                              |
| <a href="#">Default UTC Time Zone</a>          |                                                                                                                              |
| <a href="#">Eagerly Validate Declarations</a>  |                                                                                                                              |

| CEL option, library or language feature              | Included                                                                                    |
|------------------------------------------------------|---------------------------------------------------------------------------------------------|

| Kubernetes regex library                             | See <a href="#">Kubernetes regex library</a>                                                |
| Kubernetes URL library                               | See <a href="#">Kubernetes URL library</a>                                                  |
| Kubernetes authorizer library                        | See <a href="#">Kubernetes authorizer library</a>                                           |
| Kubernetes quantity library                          | See <a href="#">Kubernetes quantity library</a>                                             |
| CEL optional types                                   | See <a href="#">CEL optional types</a>                                                      |
| CEL CrossTypeNumericComparisons                      | See <a href="#">CEL CrossTypeNumericComparisons</a>                                         |

CEL functions, features and language settings support Kubernetes control plane rollbacks. For example, *CEL Optional Values* was introduced at Kubernetes 1.29 and so only API servers at that version or newer will accept write requests to CEL expressions that use *CEL Optional Values*. However, when a cluster is rolled back to Kubernetes 1.28 CEL expressions using "CEL Optional Values" that are already stored in API resources will continue to evaluate correctly.

## Kubernetes CEL libraries

In addition to the CEL community libraries, Kubernetes includes CEL libraries that are available everywhere CEL is used in Kubernetes.

### Kubernetes list library

The list library includes `indexOf` and `lastIndexOf`, which work similar to the strings functions of the same names. These functions either the first or last positional index of the provided element in the list.

The list library also includes `min`, `max` and `sum`. Sum is supported on all number types as well as the duration type. Min and max are supported on all comparable types.

`isSorted` is also provided as a convenience function and is supported on all comparable types.

Examples:

Examples of CEL expressions using list library functions

| CEL Expression                                                                                   | Purpose                                                   |
|--------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| <code>names.isSorted()</code>                                                                    | Verify that a list of names is kept in alphabetical order |
| <code>items.map(x, x.weight).sum() == 1.0</code>                                                 | Verify that the "weights" of a list of objects sum to 1.0 |
| <code>lowPriorities.map(x, x.priority).max() &lt; highPriorities.map(x, x.priority).min()</code> | Verify that two sets of priorities do not overlap         |
| <code>names.indexOf('should-be-first') == 1</code>                                               | Require that the first name in a list if a specific value |

See the [Kubernetes List Library](#) godoc for more information.

## Kubernetes regex library

In addition to the `matches` function provided by the CEL standard library, the regex library provides `find` and `findAll`, enabling a much wider range of regex operations.

Examples:

Examples of CEL expressions using regex library functions

| CEL Expression                                                            | Purpose                                                  |
|---------------------------------------------------------------------------|----------------------------------------------------------|
| <code>"abc 123".find('[0-9]*')</code>                                     | Find the first number in a string                        |
| <code>"1, 2, 3, 4".findAll('[0-9]*').map(x, int(x)).sum() &lt; 100</code> | Verify that the numbers in a string sum to less than 100 |

See the [Kubernetes regex library](#) godoc for more information.

## Kubernetes URL library

To make it easier and safer to process URLs, the following functions have been added:

- `isURL(string)` checks if a string is a valid URL according to the [Go's net/url](#) package. The string must be an absolute URL.
- `url(string)` URL converts a string to a URL or results in an error if the string is not a valid URL.

Once parsed via the `url` function, the resulting URL object has `getScheme`, `getHost`, `getHostname`, `getPort`, `getEscapedPath` and `getQuery` accessors.

Examples:

Examples of CEL expressions using URL library functions

| CEL Expression                                                             | Purpose                                        |
|----------------------------------------------------------------------------|------------------------------------------------|
| <code>url('https://example.com:80/').getHost()</code>                      | Get the 'example.com:80' host part of the URL. |
| <code>url('https://example.com/path with spaces/').getEscapedPath()</code> | Returns '/path%20with%20spaces/'               |

See the [Kubernetes URL library](#) godoc for more information.

## Kubernetes authorizer library

For CEL expressions in the API where a variable of type `Authorizer` is available, the authorizer may be used to perform authorization checks for the principal (authenticated user) of the request.

API resource checks are performed as follows:

1. Specify the group and resource to check: `Authorizer.group(string).resource(string) ResourceCheck`
2. Optionally call any combination of the following builder functions to further narrow the authorization check. Note that these functions return the receiver type and can be chained:
  - `ResourceCheck.subresource(string) ResourceCheck`
  - `ResourceCheck.namespace(string) ResourceCheck`
  - `ResourceCheck.name(string) ResourceCheck`
1. Call `ResourceCheck.check(verb string) Decision` to perform the authorization check.
2. Call `allowed() bool` or `reason() string` to inspect the result of the authorization check.

Non-resource authorization performed are used as follows:

1. specify only a path: `Authorizer.path(string) PathCheck`
2. Call `PathCheck.check(httpVerb string) Decision` to perform the authorization check.
3. Call `allowed() bool` or `reason() string` to inspect the result of the authorization check.

To perform an authorization check for a service account:

- `Authorizer.serviceAccount(namespace string, name string) Authorizer`

Examples of CEL expressions using URL library functions

| CEL Expression                                                                                    | Purpose                                                                                                    |
|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <code>authorizer.group('').resource('pods').namespace('default').check('create').allowed()</code> | Returns true if the principal (user or service account) is allowed create pods in the 'default' namespace. |
| <code>authorizer.path('/healthz').check('get').allowed()</code>                                   | Checks if the principal (user or service account) is authorized to make HTTP GET requests to the /         |

| CEL Expression                                                                                                          | Purpose                                                            |
|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
|                                                                                                                         | healthz API path.                                                  |
| <code>authorizer.serviceAccount('default', 'myserviceaccount').resource('deployments').check('delete').allowed()</code> | Checks if the service account is authorized to delete deployments. |

See the [Kubernetes Authz library](#) godoc for more information.

## Kubernetes quantity library

Kubernetes 1.28 adds support for manipulating quantity strings (ex 1.5G, 512k, 20Mi)

- `isQuantity(string)` checks if a string is a valid Quantity according to [Kubernetes' resource.Quantity](#).
- `quantity(string)` Quantity converts a string to a Quantity or results in an error if the string is not a valid quantity.

Once parsed via the quantity function, the resulting Quantity object has the following library of member functions:

Available member functions of a Quantity

| Member Function                              | CEL Return Value | Description                                                                                                                                                           |
|----------------------------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>isInteger()</code>                     | bool             | returns true if and only if <code>asInteger</code> is safe to call without an error                                                                                   |
| <code>asInteger()</code>                     | int              | returns a representation of the current value as an int64 if possible or results in an error if conversion would result in overflow or loss of precision.             |
| <code>asApproximateFloat()</code>            | float            | returns a float64 representation of the quantity which may lose precision. If the value of the quantity is outside the range of a float64 +Inf/-Inf will be returned. |
| <code>sign()</code>                          | int              | Returns 1 if the quantity is positive, -1 if it is negative. 0 if it is zero                                                                                          |
| <code>add(&lt;Quantity&gt;)</code>           | Quantity         | Returns sum of two quantities                                                                                                                                         |
| <code>add(&lt;int&gt;)</code>                | Quantity         | Returns sum of quantity and an integer                                                                                                                                |
| <code>sub(&lt;Quantity&gt;)</code>           | Quantity         | Returns difference between two quantities                                                                                                                             |
| <code>sub(&lt;int&gt;)</code>                | Quantity         | Returns difference between a quantity and an integer                                                                                                                  |
| <code>isLessThan(&lt;Quantity&gt;)</code>    | bool             | Returns true if and only if the receiver is less than the operand                                                                                                     |
| <code>isGreaterThan(&lt;Quantity&gt;)</code> | bool             | Returns true if and only if the receiver is greater than the operand                                                                                                  |
| <code>compareTo(&lt;Quantity&gt;)</code>     | int              | Compares receiver to operand and returns 0 if they are equal, 1 if the receiver is greater, or -1 if the receiver is less than the operand                            |

Examples:

### Examples of CEL expressions using URL library functions

[illegible]

# Type checking

CEL is a gradually typed language.

Some Kubernetes API fields contain fully type checked CEL expressions. For example, [CustomResourceDefinitions Validation Rules](#) are fully type checked.

Some Kubernetes API fields contain partially type checked CEL expressions. A partially type checked expression is an expressions where some of the variables are statically typed but others are dynamically typed. For example, in the CEL expressions of [ValidatingAdmissionPolicies](#) the request variable is typed, but the object variable is dynamically typed. As a result, an expression containing request.name would fail type checking because the name field is not defined. However, object.name would pass type checking even when the name field is not defined for the resource kinds that object refers to, because object is dynamically typed.

The `has()` macro in CEL may be used in CEL expressions to check if a field of a dynamically typed variable is accessible before attempting to access the field's value. For example:

```
has(object.namex) ? object.namex == 'special' : request.name == 'special'
```

# Type system integration

Table showing the relationship between OpenAPIv3 types and CEL types

| OpenAPIv3 type                                     | CEL type                                                                                                                     |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| 'object' with Properties                           | object / "message type" (type(<object>) evaluates to selfType<uniqueNumber>.path.to.object.from.self                         |
| 'object' with AdditionalProperties                 | map                                                                                                                          |
| 'object' with x-kubernetes-embedded-type           | object / "message type", 'apiVersion', 'kind', 'metadata.name' and 'metadata.generateName' are implicitly included in schema |
| 'object' with x-kubernetes-preserve-unknown-fields | object / "message type", unknown fields are NOT accessible in CEL expression                                                 |
| x-kubernetes-int-or-string                         | union of int or string, self.intOrString < 100    self.intOrString == '50%' evaluates to true for both 50 and "50%"          |
| 'array'                                            | list                                                                                                                         |
| 'array' with x-kubernetes-list-type=map            | list with map based Equality & unique key guarantees                                                                         |
| 'array' with x-kubernetes-list-type=set            | list with set based Equality & unique entry guarantees                                                                       |
| 'boolean'                                          | boolean                                                                                                                      |
| 'number' (all formats)                             | double                                                                                                                       |
| 'integer' (all formats)                            | int (64)                                                                                                                     |
| <i>no equivalent</i>                               | uint (64)                                                                                                                    |
| 'null'                                             | null_type                                                                                                                    |
| 'string'                                           | string                                                                                                                       |
| 'string' with format=byte (base64 encoded)         | bytes                                                                                                                        |
| 'string' with format=date                          | timestamp (google.protobuf.Timestamp)                                                                                        |
| 'string' with format=datetime                      | timestamp (google.protobuf.Timestamp)                                                                                        |
| 'string' with format=duration                      | duration (google.protobuf.Duration)                                                                                          |

Also see: [CEL types](#), [OpenAPI types](#), [Kubernetes Structural Schemas](#).

Equality comparison for arrays with x-kubernetes-list-type of set or map ignores element order. For example `[1, 2] == [2, 1]` if the arrays represent Kubernetes set values.

Concatenation on arrays with x-kubernetes-list-type use the semantics of the list type:

- set: `X + Y` performs a union where the array positions of all elements in X are preserved and non-intersecting elements in Y are appended, retaining their partial order.
- map: `X + Y` performs a merge where the array positions of all keys in X are preserved but the values are overwritten by values in Y when the key sets of X and Y intersect. Elements in Y with non-intersecting keys are appended, retaining their partial order.

# Escaping

Only Kubernetes resource property names of the form `[a-zA-Z_./][a-zA-Z0-9_./]*` are accessible from CEL. Accessible property names are escaped according to the following rules when accessed in the expression:

Table of CEL identifier escaping rules

| escape sequence              | property name equivalent             |
|------------------------------|--------------------------------------|
| <code>__underscores__</code> | <code>__</code>                      |
| <code>__dot__</code>         | <code>.</code>                       |
| <code>__dash__</code>        | <code>-</code>                       |
| <code>__slash__</code>       | <code>/</code>                       |
| <code>__{keyword}__</code>   | <a href="#">CEL RESERVED keyword</a> |

When you escape any of CEL's **RESERVED** keywords you need to match the exact property name use the underscore escaping (for example, `int` in the word `sprint` would not be escaped and nor would it need to be).

Examples on escaping:

Examples escaped CEL identifiers

| property name          | rule with escaped property name                 |
|------------------------|-------------------------------------------------|
| <code>namespace</code> | <code>self.__namespace__ &gt; 0</code>          |
| <code>x-prop</code>    | <code>self.x__dash__prop &gt; 0</code>          |
| <code>redact_d</code>  | <code>self.redact__underscores__d &gt; 0</code> |
| <code>string</code>    | <code>self.startsWith('kube')</code>            |

## Resource constraints

CEL is non-Turing complete and offers a variety of production safety controls to limit execution time. CEL's *resource constraint* features provide feedback to developers about expression complexity and help protect the API server from excessive resource consumption during evaluation. CEL's resource constraint features are used to prevent CEL evaluation from consuming excessive API server resources.

A key element of the resource constraint features is a *cost unit* that CEL defines as a way of tracking CPU utilization. Cost units are independent of system load and hardware. Cost units are also deterministic; for any given CEL expression and input data, evaluation of the expression by the CEL interpreter will always result in the same cost.

Many of CEL's core operations have fixed costs. The simplest operations, such as comparisons (e.g. `<`) have a cost of 1. Some have a higher fixed cost, for example list literal declarations have a fixed base cost of 40 cost units.

Calls to functions implemented in native code approximate cost based on the time complexity of the operation. For example: operations that use regular expressions, such as `match` and `find`, are estimated using an approximated cost of `length(regexString)*length(inputString)`. The approximated cost reflects the worst case time complexity of Go's RE2 implementation.

## Runtime cost budget

All CEL expressions evaluated by Kubernetes are constrained by a runtime cost budget. The runtime cost budget is an estimate of actual CPU utilization computed by incrementing a cost unit counter while interpreting a CEL expression. If the CEL interpreter executes too many instructions, the runtime cost budget will be exceeded, execution of the expressions will be halted, and an error will result.

Some Kubernetes resources define an additional runtime cost budget that bounds the execution of multiple expressions. If the sum total of the cost of expressions exceed the budget, execution of the expressions will be halted, and an error will result. For example the validation of a custom resource has a *per-validation* runtime cost budget for all [Validation Rules](#) evaluated to validate the custom resource.

## Estimated cost limits

For some Kubernetes resources, the API server may also check if worst case estimated running time of CEL expressions would be prohibitively expensive to execute. If so, the API server prevent the CEL expression from being written to API resources by rejecting create or update operations containing the CEL expression to the API resources. This feature offers a stronger assurance that CEL expressions written to the API resource will be evaluate at runtime without exceeding the runtime cost budget.

# Kubernetes Deprecation Policy

This document details the deprecation policy for various facets of the system.

Kubernetes is a large system with many components and many contributors. As with any such software, the feature set naturally evolves over time, and sometimes a feature may need to be removed. This could include an API, a flag, or even an entire feature. To avoid breaking existing users, Kubernetes follows a deprecation policy for aspects of the system that are slated to be removed.

## Deprecating parts of the API

Since Kubernetes is an API-driven system, the API has evolved over time to reflect the evolving understanding of the problem space. The Kubernetes API is actually a set of APIs, called "API groups", and each API group is independently versioned. [API versions](#) fall into 3 main tracks, each of which has different policies for deprecation:

| Example  | Track                            |
|----------|----------------------------------|
| v1       | GA (generally available, stable) |
| v1beta1  | Beta (pre-release)               |
| v1alpha1 | Alpha (experimental)             |

A given release of Kubernetes can support any number of API groups and any number of versions of each.

The following rules govern the deprecation of elements of the API. This includes:

- REST resources (aka API objects)
- Fields of REST resources
- Annotations on REST resources, including "beta" annotations but not including "alpha" annotations.
- Enumerated or constant values
- Component config structures

These rules are enforced between official releases, not between arbitrary commits to master or release branches.

**Rule #1: API elements may only be removed by incrementing the version of the API group.**

Once an API element has been added to an API group at a particular version, it can not be removed from that version or have its behavior significantly changed, regardless of track.

**Note:**

For historical reasons, there are 2 "monolithic" API groups - "core" (no group name) and "extensions". Resources will incrementally be moved from these legacy API groups into more domain-specific API groups.

**Rule #2: API objects must be able to round-trip between API versions in a given release without information loss, with the exception of whole REST resources that do not exist in some versions.**

For example, an object can be written as v1 and then read back as v2 and converted to v1, and the resulting v1 resource will be identical to the original. The representation in v2 might be different from v1, but the system knows how to convert between them in both directions. Additionally, any new field added in v2 must be able to round-trip to v1 and back, which means v1 might have to add an equivalent field or represent it as an annotation.

**Rule #3: An API version in a given track may not be deprecated in favor of a less stable API version.**

- GA API versions can replace beta and alpha API versions.
- Beta API versions can replace earlier beta and alpha API versions, but *may not* replace GA API versions.
- Alpha API versions can replace earlier alpha API versions, but *may not* replace GA or beta API versions.

**Rule #4a: API lifetime is determined by the API stability level**

- GA API versions may be marked as deprecated, but must not be removed within a major version of Kubernetes
- Beta API versions are deprecated no more than 9 months or 3 minor releases after introduction (whichever is longer), and are no longer served 9 months or 3 minor releases after deprecation (whichever is longer)
- Alpha API versions may be removed in any release without prior deprecation notice

This ensures beta API support covers the [maximum supported version skew of 2 releases](#), and that APIs don't stagnate on unstable beta versions, accumulating production usage that will be disrupted when support for the beta API ends.

**Note:**

There are no current plans for a major version revision of Kubernetes that removes GA APIs.

**Note:**

Until [#52185](#) is resolved, no API versions that have been persisted to storage may be removed. Serving REST endpoints for those versions may be disabled (subject to the deprecation timelines in this document), but the API server must remain capable of decoding/converting previously persisted data from storage.

**Rule #4b: The "preferred" API version and the "storage version" for a given group may not advance until after a release has been made that supports both the new version and the previous version**

Users must be able to upgrade to a new release of Kubernetes and then roll back to a previous release, without converting anything to the new API version or suffering breakages (unless they explicitly used features only available in the newer version). This is particularly evident in the stored representation of objects.

All of this is best illustrated by examples. Imagine a Kubernetes release, version X, which introduces a new API group. A new Kubernetes release is made every approximately 4 months (3 per year). The following table describes which API versions are supported in a series of subsequent releases.

| Release | API Versions                                   | Preferred/<br>Storage Version | Notes                                                                                              |
|---------|------------------------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------|
| X       | v1alpha1                                       | v1alpha1                      |                                                                                                    |
| X+1     | v1alpha2                                       | v1alpha2                      | <ul style="list-style-type: none"><li>• v1alpha1 is removed, "action required" relnote</li></ul>   |
| X+2     | v1beta1                                        | v1beta1                       | <ul style="list-style-type: none"><li>• v1alpha2 is removed, "action required" relnote</li></ul>   |
| X+3     | v1beta2, v1beta1 (deprecated)                  | v1beta1                       | <ul style="list-style-type: none"><li>• v1beta1 is deprecated, "action required" relnote</li></ul> |
| X+4     | v1beta2, v1beta1 (deprecated)                  | v1beta2                       |                                                                                                    |
| X+5     | v1, v1beta1 (deprecated), v1beta2 (deprecated) | v1beta2                       | <ul style="list-style-type: none"><li>• v1beta2 is deprecated, "action required" relnote</li></ul> |
| X+6     | v1, v1beta2 (deprecated)                       | v1                            | <ul style="list-style-type: none"><li>• v1beta1 is removed, "action required" relnote</li></ul>    |

| Release | API Versions                                                    | Preferred/<br>Storage Version | Notes                                                                                                                                                                |
|---------|-----------------------------------------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X+7     | v1, v1beta2 (deprecated)                                        | v1                            |                                                                                                                                                                      |
| X+8     | v2alpha1, v1                                                    | v1                            | <ul style="list-style-type: none"> <li>v1beta2 is removed, "action required" relnote</li> </ul>                                                                      |
| X+9     | v2alpha2, v1                                                    | v1                            | <ul style="list-style-type: none"> <li>v2alpha1 is removed, "action required" relnote</li> </ul>                                                                     |
| X+10    | v2beta1, v1                                                     | v1                            | <ul style="list-style-type: none"> <li>v2alpha2 is removed, "action required" relnote</li> </ul>                                                                     |
| X+11    | v2beta2, v2beta1 (deprecated), v1                               | v1                            | <ul style="list-style-type: none"> <li>v2beta1 is deprecated, "action required" relnote</li> </ul>                                                                   |
| X+12    | v2, v2beta2 (deprecated), v2beta1 (deprecated), v1 (deprecated) | v1                            | <ul style="list-style-type: none"> <li>v2beta2 is deprecated, "action required" relnote</li> <li>v1 is deprecated in favor of v2, but will not be removed</li> </ul> |
| X+13    | v2, v2beta1 (deprecated), v2beta2 (deprecated), v1 (deprecated) | v2                            |                                                                                                                                                                      |
| X+14    | v2, v2beta2 (deprecated), v1 (deprecated)                       | v2                            | <ul style="list-style-type: none"> <li>v2beta1 is removed, "action required" relnote</li> </ul>                                                                      |
| X+15    | v2, v1 (deprecated)                                             | v2                            | <ul style="list-style-type: none"> <li>v2beta2 is removed, "action required" relnote</li> </ul>                                                                      |

## REST resources (aka API objects)

Consider a hypothetical REST resource named Widget, which was present in API v1 in the above timeline, and which needs to be deprecated. We document and [announce](#) the deprecation in sync with release X+1. The Widget resource still exists in API version v1 (deprecated) but not in v2alpha1. The Widget resource continues to exist and function in releases up to and including X+8. Only in release X+9, when API v1 has aged out, does the Widget resource cease to exist, and the behavior get removed.

Starting in Kubernetes v1.19, making an API request to a deprecated REST API endpoint:

1. Returns a Warning header (as defined in [RFC7234, Section 5.5](#)) in the API response.
2. Adds a "k8s.io/deprecated":"true" annotation to the [audit event](#) recorded for the request.

- Sets an `apiserver_requested_deprecated_apis` gauge metric to 1 in the kube-apiserver process. The metric has labels for group, version, resource, subresource that can be joined to the `apiserver_request_total` metric, and a `removed_release` label that indicates the Kubernetes release in which the API will no longer be served. The following Prometheus query returns information about requests made to deprecated APIs which will be removed in v1.22:

```
apiserver_requested_deprecated_apis{removed_release="1.22"} * on(group,version,resource,subresource) group_right() apiserver_request_total
```

## Fields of REST resources

As with whole REST resources, an individual field which was present in API v1 must exist and function until API v1 is removed. Unlike whole resources, the v2 APIs may choose a different representation for the field, as long as it can be round-tripped. For example a v1 field named "magnitude" which was deprecated might be named "deprecatedMagnitude" in API v2. When v1 is eventually removed, the deprecated field can be removed from v2.

## Enumerated or constant values

As with whole REST resources and fields thereof, a constant value which was supported in API v1 must exist and function until API v1 is removed.

## Component config structures

Component configs are versioned and managed similar to REST resources.

## Future work

Over time, Kubernetes will introduce more fine-grained API versions, at which point these rules will be adjusted as needed.

## Deprecating a flag or CLI

The Kubernetes system is comprised of several different programs cooperating. Sometimes, a Kubernetes release might remove flags or CLI commands (collectively "CLI elements") in these programs. The individual programs naturally sort into two main groups - user-facing and admin-facing programs, which vary slightly in their deprecation policies. Unless a flag is explicitly prefixed or documented as "alpha" or "beta", it is considered GA.

CLI elements are effectively part of the API to the system, but since they are not versioned in the same way as the REST API, the rules for deprecation are as follows:

**Rule #5a: CLI elements of user-facing components (e.g. kubectl) must function after their announced deprecation for no less than:**

- **GA: 12 months or 2 releases (whichever is longer)**
- **Beta: 3 months or 1 release (whichever is longer)**
- **Alpha: 0 releases**

**Rule #5b: CLI elements of admin-facing components (e.g. kubelet) must function after their announced deprecation for no less than:**

- GA: 6 months or 1 release (whichever is longer)
- Beta: 3 months or 1 release (whichever is longer)
- Alpha: 0 releases

**Rule #5c: Command line interface (CLI) elements cannot be deprecated in favor of less stable CLI elements**

Similar to the Rule #3 for APIs, if an element of a command line interface is being replaced with an alternative implementation, such as by renaming an existing element, or by switching to use configuration sourced from a file instead of a command line argument, that recommended alternative must be of the same or higher stability level.

**Rule #6: Deprecated CLI elements must emit warnings (optionally disable) when used.**

## Deprecating a feature or behavior

Occasionally a Kubernetes release needs to deprecate some feature or behavior of the system that is not controlled by the API or CLI. In this case, the rules for deprecation are as follows:

**Rule #7: Deprecated behaviors must function for no less than 1 year after their announced deprecation.**

If the feature or behavior is being replaced with an alternative implementation that requires work to adopt the change, there should be an effort to simplify the transition whenever possible. If an alternative implementation is under Kubernetes organization control, the following rules apply:

**Rule #8: The feature or behavior must not be deprecated in favor of an alternative implementation that is less stable**

For example, a generally available feature cannot be deprecated in favor of a Beta replacement. The Kubernetes project does, however, encourage users to adopt and transitions to alternative implementations even before they reach the same maturity level. This is particularly important for exploring new use cases of a feature or getting an early feedback on the replacement.

Alternative implementations may sometimes be external tools or products, for example a feature may move from the kubelet to container runtime that is not under Kubernetes project control. In such cases, the rule cannot be applied, but there must be an effort to ensure that there is a transition path that does not compromise on components' maturity levels. In the example with container runtimes, the effort may involve trying to ensure that popular container runtimes have versions that offer the same level of stability while implementing that replacement behavior.

Deprecation rules for features and behaviors do not imply that all changes to the system are governed by this policy. These rules applies only to significant, user-visible behaviors which impact the correctness of applications running on Kubernetes or that impact the administration of Kubernetes clusters, and which are being removed entirely.

An exception to the above rule is *feature gates*. Feature gates are key=value pairs that allow for users to enable/disable experimental features.

Feature gates are intended to cover the development life cycle of a feature - they are not intended to be long-term APIs. As such, they are expected to be deprecated and removed after a feature becomes GA or is dropped.

As a feature moves through the stages, the associated feature gate evolves. The feature life cycle matched to its corresponding feature gate is:

- Alpha: the feature gate is disabled by default and can be enabled by the user.
- Beta: the feature gate is enabled by default and can be disabled by the user.
- GA: the feature gate is deprecated (see "[Deprecation](#)") and becomes non-operational.
- GA, deprecation window complete: the feature gate is removed and calls to it are no longer accepted.

## Deprecation

Features can be removed at any point in the life cycle prior to GA. When features are removed prior to GA, their associated feature gates are also deprecated.

When an invocation tries to disable a non-operational feature gate, the call fails in order to avoid unsupported scenarios that might otherwise run silently.

In some cases, removing pre-GA features requires considerable time. Feature gates can remain operational until their associated feature is fully removed, at which point the feature gate itself can be deprecated.

When removing a feature gate for a GA feature also requires considerable time, calls to feature gates may remain operational if the feature gate has no effect on the feature, and if the feature gate causes no errors.

Features intended to be disabled by users should include a mechanism for disabling the feature in the associated feature gate.

Versioning for feature gates is different from the previously discussed components, therefore the rules for deprecation are as follows:

**Rule #9: Feature gates must be deprecated when the corresponding feature they control transitions a lifecycle stage as follows. Feature gates must function for no less than:**

- Beta feature to GA: 6 months or 2 releases (whichever is longer)
- Beta feature to EOL: 3 months or 1 release (whichever is longer)
- Alpha feature to EOL: 0 releases

**Rule #10: Deprecated feature gates must respond with a warning when used. When a feature gate is deprecated it must be documented in both in the release notes and the corresponding CLI help. Both warnings and documentation must indicate whether a feature gate is non-operational.**

## Deprecating a metric

Each component of the Kubernetes control-plane exposes metrics (usually the /metrics endpoint), which are typically ingested by cluster administrators. Not all metrics are the same: some metrics are commonly used as SLIs or used to determine SLOs, these tend to have greater

import. Other metrics are more experimental in nature or are used primarily in the Kubernetes development process.

Accordingly, metrics fall under three stability classes (ALPHA, BETA, STABLE); this impacts removal of a metric during a Kubernetes release. These classes are determined by the perceived importance of the metric. The rules for deprecating and removing a metric are as follows:

**Rule #11a: Metrics, for the corresponding stability class, must function for no less than:**

- **STABLE: 4 releases or 12 months (whichever is longer)**
- **BETA: 2 releases or 8 months (whichever is longer)**
- **ALPHA: 0 releases**

**Rule #11b: Metrics, after their *announced deprecation*, must function for no less than:**

- **STABLE: 3 releases or 9 months (whichever is longer)**
- **BETA: 1 releases or 4 months (whichever is longer)**
- **ALPHA: 0 releases**

Deprecated metrics will have their description text prefixed with a deprecation notice string '(Deprecated from x.y)' and a warning log will be emitted during metric registration. Like their stable undeprecated counterparts, deprecated metrics will be automatically registered to the metrics endpoint and therefore visible.

On a subsequent release (when the metric's `deprecatedVersion` is equal to `current_kubernetes_version - 3`), a deprecated metric will become a *hidden* metric. **Unlike** their deprecated counterparts, hidden metrics will *no longer* be automatically registered to the metrics endpoint (hence hidden). However, they can be explicitly enabled through a command line flag on the binary (`--show-hidden-metrics-for-version=`). This provides cluster admins an escape hatch to properly migrate off of a deprecated metric, if they were not able to react to the earlier deprecation warnings. Hidden metrics should be deleted after one release.

## Exceptions

No policy can cover every possible situation. This policy is a living document, and will evolve over time. In practice, there will be situations that do not fit neatly into this policy, or for which this policy becomes a serious impediment. Such situations should be discussed with SIGs and project leaders to find the best solutions for those specific cases, always bearing in mind that Kubernetes is committed to being a stable system that, as much as possible, never breaks users. Exceptions will always be announced in all relevant release notes.

## Deprecated API Migration Guide

As the Kubernetes API evolves, APIs are periodically reorganized or upgraded. When APIs evolve, the old API is deprecated and eventually removed. This page contains information you need to know when migrating from deprecated API versions to newer and more stable API versions.

# Removed APIs by release

## v1.32

The **v1.32** release will stop serving the following deprecated API versions:

### Flow control resources

The **flowcontrol.apiserver.k8s.io/v1beta3** API version of FlowSchema and PriorityLevelConfiguration will no longer be served in v1.32.

- Migrate manifests and API clients to use the **flowcontrol.apiserver.k8s.io/v1** API version, available since v1.29.
- All existing persisted objects are accessible via the new API
- Notable changes in **flowcontrol.apiserver.k8s.io/v1**:
  - The PriorityLevelConfiguration spec.limited.nominalConcurrencyShares field only defaults to 30 when unspecified, and an explicit value of 0 is not changed to 30.

## v1.29

The **v1.29** release stopped serving the following deprecated API versions:

### Flow control resources

The **flowcontrol.apiserver.k8s.io/v1beta2** API version of FlowSchema and PriorityLevelConfiguration is no longer served as of v1.29.

- Migrate manifests and API clients to use the **flowcontrol.apiserver.k8s.io/v1** API version, available since v1.29, or the **flowcontrol.apiserver.k8s.io/v1beta3** API version, available since v1.26.
- All existing persisted objects are accessible via the new API
- Notable changes in **flowcontrol.apiserver.k8s.io/v1**:
  - The PriorityLevelConfiguration spec.limited.assuredConcurrencyShares field is renamed to spec.limited.nominalConcurrencyShares and only defaults to 30 when unspecified, and an explicit value of 0 is not changed to 30.
- Notable changes in **flowcontrol.apiserver.k8s.io/v1beta3**:
  - The PriorityLevelConfiguration spec.limited.assuredConcurrencyShares field is renamed to spec.limited.nominalConcurrencyShares

## v1.27

The **v1.27** release stopped serving the following deprecated API versions:

### CSIStorageCapacity

The **storage.k8s.io/v1beta1** API version of CSIStorageCapacity is no longer served as of v1.27.

- Migrate manifests and API clients to use the **storage.k8s.io/v1** API version, available since v1.24.
- All existing persisted objects are accessible via the new API
- No notable changes

## v1.26

The **v1.26** release stopped serving the following deprecated API versions:

### Flow control resources

The **flowcontrol.apiserver.k8s.io/v1beta1** API version of FlowSchema and PriorityLevelConfiguration is no longer served as of v1.26.

- Migrate manifests and API clients to use the **flowcontrol.apiserver.k8s.io/v1beta2** API version.
- All existing persisted objects are accessible via the new API
- No notable changes

### HorizontalPodAutoscaler

The **autoscaling/v2beta2** API version of HorizontalPodAutoscaler is no longer served as of v1.26.

- Migrate manifests and API clients to use the **autoscaling/v2** API version, available since v1.23.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - targetAverageUtilization is replaced with target.averageUtilization and target.type: Utilization. See [Autoscaling on multiple metrics and custom metrics](#).

## v1.25

The **v1.25** release stopped serving the following deprecated API versions:

### CronJob

The **batch/v1beta1** API version of CronJob is no longer served as of v1.25.

- Migrate manifests and API clients to use the **batch/v1** API version, available since v1.21.
- All existing persisted objects are accessible via the new API
- No notable changes

### EndpointSlice

The **discovery.k8s.io/v1beta1** API version of EndpointSlice is no longer served as of v1.25.

- Migrate manifests and API clients to use the **discovery.k8s.io/v1** API version, available since v1.21.
- All existing persisted objects are accessible via the new API
- Notable changes in **discovery.k8s.io/v1**:
  - use per Endpoint nodeName field instead of deprecated topology["kubernetes.io/hostname"] field
  - use per Endpoint zone field instead of deprecated topology["topology.kubernetes.io/zone"] field
  - topology is replaced with the deprecatedTopology field which is not writable in v1

## Event

The **events.k8s.io/v1beta1** API version of Event is no longer served as of v1.25.

- Migrate manifests and API clients to use the **events.k8s.io/v1** API version, available since v1.19.
- All existing persisted objects are accessible via the new API
- Notable changes in **events.k8s.io/v1**:
  - type is limited to Normal and Warning
  - involvedObject is renamed to regarding
  - action, reason, reportingController, and reportingInstance are required when creating new **events.k8s.io/v1** Events
  - use eventTime instead of the deprecated firstTimestamp field (which is renamed to deprecatedFirstTimestamp and not permitted in new **events.k8s.io/v1** Events)
  - use series.lastObservedTime instead of the deprecated lastTimestamp field (which is renamed to deprecatedLastTimestamp and not permitted in new **events.k8s.io/v1** Events)
  - use series.count instead of the deprecated count field (which is renamed to deprecatedCount and not permitted in new **events.k8s.io/v1** Events)
  - use reportingController instead of the deprecated source.component field (which is renamed to deprecatedSource.component and not permitted in new **events.k8s.io/v1** Events)
  - use reportingInstance instead of the deprecated source.host field (which is renamed to deprecatedSource.host and not permitted in new **events.k8s.io/v1** Events)

## HorizontalPodAutoscaler

The **autoscaling/v2beta1** API version of HorizontalPodAutoscaler is no longer served as of v1.25.

- Migrate manifests and API clients to use the **autoscaling/v2** API version, available since v1.23.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - targetAverageUtilization is replaced with target.averageUtilization and target.type: Utilization. See [Autoscaling on multiple metrics and custom metrics](#).

## PodDisruptionBudget

The **policy/v1beta1** API version of PodDisruptionBudget is no longer served as of v1.25.

- Migrate manifests and API clients to use the **policy/v1** API version, available since v1.21.
- All existing persisted objects are accessible via the new API
- Notable changes in **policy/v1**:
  - an empty spec.selector ({} ) written to a policy/v1 PodDisruptionBudget selects all pods in the namespace (in policy/v1beta1 an empty spec.selector selected no pods). An unset spec.selector selects no pods in either API version.

## PodSecurityPolicy

PodSecurityPolicy in the **policy/v1beta1** API version is no longer served as of v1.25, and the PodSecurityPolicy admission controller will be removed.

Migrate to [Pod Security Admission](#) or a [3rd party admission webhook](#). For a migration guide, see [Migrate from PodSecurityPolicy to the Built-In PodSecurity Admission Controller](#). For more information on the deprecation, see [PodSecurityPolicy Deprecation: Past, Present, and Future](#).

## RuntimeClass

RuntimeClass in the **node.k8s.io/v1beta1** API version is no longer served as of v1.25.

- Migrate manifests and API clients to use the **node.k8s.io/v1** API version, available since v1.20.
- All existing persisted objects are accessible via the new API
- No notable changes

## v1.22

The **v1.22** release stopped serving the following deprecated API versions:

### Webhook resources

The **admissionregistration.k8s.io/v1beta1** API version of MutatingWebhookConfiguration and ValidatingWebhookConfiguration is no longer served as of v1.22.

- Migrate manifests and API clients to use the **admissionregistration.k8s.io/v1** API version, available since v1.16.
- All existing persisted objects are accessible via the new APIs
- Notable changes:
  - `webhooks[*].failurePolicy` default changed from Ignore to Fail for v1
  - `webhooks[*].matchPolicy` default changed from Exact to Equivalent for v1
  - `webhooks[*].timeoutSeconds` default changed from 30s to 10s for v1
  - `webhooks[*].sideEffects` default value is removed, and the field made required, and only None and NoneOnDryRun are permitted for v1
  - `webhooks[*].admissionReviewVersions` default value is removed and the field made required for v1 (supported versions for AdmissionReview are v1 and v1beta1)
  - `webhooks[*].name` must be unique in the list for objects created via `admissionregistration.k8s.io/v1`

## CustomResourceDefinition

The **apiextensions.k8s.io/v1beta1** API version of CustomResourceDefinition is no longer served as of v1.22.

- Migrate manifests and API clients to use the **apiextensions.k8s.io/v1** API version, available since v1.16.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - `spec.scope` is no longer defaulted to Namespaced and must be explicitly specified
  - `spec.version` is removed in v1; use `spec.versions` instead
  - `spec.validation` is removed in v1; use `spec.versions[*].schema` instead
  - `spec.subresources` is removed in v1; use `spec.versions[*].subresources` instead
  - `spec.additionalPrinterColumns` is removed in v1; use `spec.versions[*].additionalPrinterColumns` instead

- `spec.conversion.webhookClientConfig` is moved to `spec.conversion.webhook.clientConfig` in v1
- `spec.conversion.conversionReviewVersions` is moved to `spec.conversion.webhook.conversionReviewVersions` in v1
- `spec.versions[*].schema.openAPIV3Schema` is now required when creating v1 `CustomResourceDefinition` objects, and must be a [structural schema](#)
- `spec.preserveUnknownFields: true` is disallowed when creating v1 `CustomResourceDefinition` objects; it must be specified within schema definitions as `x-kubernetes-preserve-unknown-fields: true`
- In additionalPrinterColumns items, the JSONPath field was renamed to `jsonPath` in v1 (fixes [#66531](#))

## APIService

The **apiregistration.k8s.io/v1beta1** API version of APIService is no longer served as of v1.22.

- Migrate manifests and API clients to use the **apiregistration.k8s.io/v1** API version, available since v1.10.
- All existing persisted objects are accessible via the new API
- No notable changes

## TokenReview

The **authentication.k8s.io/v1beta1** API version of TokenReview is no longer served as of v1.22.

- Migrate manifests and API clients to use the **authentication.k8s.io/v1** API version, available since v1.6.
- No notable changes

## SubjectAccessReview resources

The **authorization.k8s.io/v1beta1** API version of LocalSubjectAccessReview, SelfSubjectAccessReview, SubjectAccessReview, and SelfSubjectRulesReview is no longer served as of v1.22.

- Migrate manifests and API clients to use the **authorization.k8s.io/v1** API version, available since v1.6.
- Notable changes:
  - `spec.group` was renamed to `spec.groups` in v1 (fixes [#32709](#))

## CertificateSigningRequest

The **certificates.k8s.io/v1beta1** API version of CertificateSigningRequest is no longer served as of v1.22.

- Migrate manifests and API clients to use the **certificates.k8s.io/v1** API version, available since v1.19.
- All existing persisted objects are accessible via the new API

- Notable changes in `certificates.k8s.io/v1`:
  - For API clients requesting certificates:
    - `spec.signerName` is now required (see [known Kubernetes signers](#)), and requests for `kubernetes.io/legacy-unknown` are not allowed to be created via the `certificates.k8s.io/v1` API
    - `spec.usages` is now required, may not contain duplicate values, and must only contain known usages
  - For API clients approving or signing certificates:
    - `status.conditions` may not contain duplicate types
    - `status.conditions[*].status` is now required
    - `status.certificate` must be PEM-encoded, and contain only CERTIFICATE blocks

## Lease

The **`coordination.k8s.io/v1beta1`** API version of Lease is no longer served as of v1.22.

- Migrate manifests and API clients to use the **`coordination.k8s.io/v1`** API version, available since v1.14.
- All existing persisted objects are accessible via the new API
- No notable changes

## Ingress

The **`extensions/v1beta1`** and **`networking.k8s.io/v1beta1`** API versions of Ingress is no longer served as of v1.22.

- Migrate manifests and API clients to use the **`networking.k8s.io/v1`** API version, available since v1.19.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - `spec.backend` is renamed to `spec.defaultBackend`
  - The backend `serviceName` field is renamed to `service.name`
  - Numeric backend `servicePort` fields are renamed to `service.port.number`
  - String backend `servicePort` fields are renamed to `service.port.name`
  - `pathType` is now required for each specified path. Options are `Prefix`, `Exact`, and `ImplementationSpecific`. To match the undefined v1beta1 behavior, use `ImplementationSpecific`.

## IngressClass

The **`networking.k8s.io/v1beta1`** API version of IngressClass is no longer served as of v1.22.

- Migrate manifests and API clients to use the **`networking.k8s.io/v1`** API version, available since v1.19.
- All existing persisted objects are accessible via the new API
- No notable changes

## RBAC resources

The **rbac.authorization.k8s.io/v1beta1** API version of ClusterRole, ClusterRoleBinding, Role, and RoleBinding is no longer served as of v1.22.

- Migrate manifests and API clients to use the **rbac.authorization.k8s.io/v1** API version, available since v1.8.
- All existing persisted objects are accessible via the new APIs
- No notable changes

## PriorityClass

The **scheduling.k8s.io/v1beta1** API version of PriorityClass is no longer served as of v1.22.

- Migrate manifests and API clients to use the **scheduling.k8s.io/v1** API version, available since v1.14.
- All existing persisted objects are accessible via the new API
- No notable changes

## Storage resources

The **storage.k8s.io/v1beta1** API version of CSIDriver, CSINode, StorageClass, and VolumeAttachment is no longer served as of v1.22.

- Migrate manifests and API clients to use the **storage.k8s.io/v1** API version
  - CSIDriver is available in **storage.k8s.io/v1** since v1.19.
  - CSINode is available in **storage.k8s.io/v1** since v1.17
  - StorageClass is available in **storage.k8s.io/v1** since v1.6
  - VolumeAttachment is available in **storage.k8s.io/v1** v1.13
- All existing persisted objects are accessible via the new APIs
- No notable changes

## v1.16

The **v1.16** release stopped serving the following deprecated API versions:

### NetworkPolicy

The **extensions/v1beta1** API version of NetworkPolicy is no longer served as of v1.16.

- Migrate manifests and API clients to use the **networking.k8s.io/v1** API version, available since v1.8.
- All existing persisted objects are accessible via the new API

### DaemonSet

The **extensions/v1beta1** and **apps/v1beta2** API versions of DaemonSet are no longer served as of v1.16.

- Migrate manifests and API clients to use the **apps/v1** API version, available since v1.9.
- All existing persisted objects are accessible via the new API

- Notable changes:
  - `spec.templateGeneration` is removed
  - `spec.selector` is now required and immutable after creation; use the existing template labels as the selector for seamless upgrades
  - `spec.updateStrategy.type` now defaults to `RollingUpdate` (the default in `extensions/v1beta1` was `OnDelete`)

## Deployment

The **`extensions/v1beta1`**, **`apps/v1beta1`**, and **`apps/v1beta2`** API versions of `Deployment` are no longer served as of v1.16.

- Migrate manifests and API clients to use the **`apps/v1`** API version, available since v1.9.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - `spec.rollbackTo` is removed
  - `spec.selector` is now required and immutable after creation; use the existing template labels as the selector for seamless upgrades
  - `spec.progressDeadlineSeconds` now defaults to 600 seconds (the default in `extensions/v1beta1` was no deadline)
  - `spec.revisionHistoryLimit` now defaults to 10 (the default in `apps/v1beta1` was 2, the default in `extensions/v1beta1` was to retain all)
  - `maxSurge` and `maxUnavailable` now default to 25% (the default in `extensions/v1beta1` was 1)

## StatefulSet

The **`apps/v1beta1`** and **`apps/v1beta2`** API versions of `StatefulSet` are no longer served as of v1.16.

- Migrate manifests and API clients to use the **`apps/v1`** API version, available since v1.9.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - `spec.selector` is now required and immutable after creation; use the existing template labels as the selector for seamless upgrades
  - `spec.updateStrategy.type` now defaults to `RollingUpdate` (the default in `apps/v1beta1` was `OnDelete`)

## ReplicaSet

The **`extensions/v1beta1`**, **`apps/v1beta1`**, and **`apps/v1beta2`** API versions of `ReplicaSet` are no longer served as of v1.16.

- Migrate manifests and API clients to use the **`apps/v1`** API version, available since v1.9.
- All existing persisted objects are accessible via the new API
- Notable changes:
  - `spec.selector` is now required and immutable after creation; use the existing template labels as the selector for seamless upgrades

## PodSecurityPolicy

The **extensions/v1beta1** API version of PodSecurityPolicy is no longer served as of v1.16.

- Migrate manifests and API client to use the **policy/v1beta1** API version, available since v1.10.
- Note that the **policy/v1beta1** API version of PodSecurityPolicy will be removed in v1.25.

## What to do

### Test with deprecated APIs disabled

You can test your clusters by starting an API server with specific API versions disabled to simulate upcoming removals. Add the following flag to the API server startup arguments:

```
--runtime-config=<group>/<version>=false
```

For example:

```
--runtime-config=admissionregistration.k8s.io/v1beta1=false,apiextensions.k8s.io/v1beta1,...
```

### Locate use of deprecated APIs

Use [client warnings, metrics, and audit information available in 1.19+](#) to locate use of deprecated APIs.

### Migrate to non-deprecated APIs

- Update custom integrations and controllers to call the non-deprecated APIs
- Change YAML files to reference the non-deprecated APIs

You can use the `kubectl convert` command to automatically convert an existing object:

```
kubectl convert -f <file> --output-version <group>/<version>.
```

For example, to convert an older Deployment to `apps/v1`, you can run:

```
kubectl convert -f ./my-deployment.yaml --output-version apps/v1
```

This conversion may use non-ideal default values. To learn more about a specific resource, check the Kubernetes [API reference](#).

#### Note:

The `kubectl convert` tool is not installed by default, although in fact it once was part of `kubectl` itself. For more details, you can read the [deprecation and removal issue](#) for the built-in subcommand.

To learn how to set up `kubectl convert` on your computer, visit the page that is right for your operating system: [Linux](#), [macOS](#), or [Windows](#).

# Kubernetes API health endpoints

The Kubernetes [API server](#) provides API endpoints to indicate the current status of the API server. This page describes these API endpoints and explains how you can use them.

## API endpoints for health

The Kubernetes API server provides 3 API endpoints (healthz, livez and readyz) to indicate the current status of the API server. The healthz endpoint is deprecated (since Kubernetes v1.16), and you should use the more specific livez and readyz endpoints instead. The livez endpoint can be used with the `--livez-grace-period` [flag](#) to specify the startup duration. For a graceful shutdown you can specify the `--shutdown-delay-duration` [flag](#) with the `/readyz` endpoint. Machines that check the healthz/livez/readyz of the API server should rely on the HTTP status code. A status code 200 indicates the API server is healthy/live/ready, depending on the called endpoint. The more verbose options shown below are intended to be used by human operators to debug their cluster or understand the state of the API server.

The following examples will show how you can interact with the health API endpoints.

For all endpoints, you can use the `verbose` parameter to print out the checks and their status. This can be useful for a human operator to debug the current status of the API server, it is not intended to be consumed by a machine:

```
curl -k https://localhost:6443/livez?verbose
```

or from a remote host with authentication:

```
kubectl get --raw='/readyz?verbose'
```

The output will look like this:

```
[+]ping ok
[+]log ok
[+]etcd ok
[+]poststarthook/start-kube-apiserver-admission-initializer ok
[+]poststarthook/generic-apiserver-start-informers ok
[+]poststarthook/start-apiextensions-informers ok
[+]poststarthook/start-apiextensions-controllers ok
[+]poststarthook/crd-informer-synced ok
[+]poststarthook/bootstrap-controller ok
[+]poststarthook/rbac/bootstrap-roles ok
[+]poststarthook/scheduling/bootstrap-system-priority-classes ok
[+]poststarthook/start-cluster-authentication-info-controller ok
[+]poststarthook/start-kube-aggregator-informers ok
[+]poststarthook/apiservice-registration-controller ok
[+]poststarthook/apiservice-status-available-controller ok
[+]poststarthook/kube-apiserver-autoregistration ok
[+]autoregister-completion ok
[+]poststarthook/apiservice-openapi-controller ok
healthz check passed
```

The Kubernetes API server also supports to exclude specific checks. The query parameters can also be combined like in this example:

```
curl -k 'https://localhost:6443/readyz?verbose&exclude=etcd'
```

The output show that the etcd check is excluded:

```
[+]ping ok
[+]log ok
[+]etcd excluded: ok
[+]poststarthook/start-kube-apiserver-admission-initializer ok
[+]poststarthook/generic-apiserver-start-informers ok
[+]poststarthook/start-apiextensions-informers ok
[+]poststarthook/start-apiextensions-controllers ok
[+]poststarthook/crd-informer-synced ok
[+]poststarthook/bootstrap-controller ok
[+]poststarthook/rbac/bootstrap-roles ok
[+]poststarthook/scheduling/bootstrap-system-priority-classes ok
[+]poststarthook/start-cluster-authentication-info-controller ok
[+]poststarthook/start-kube-aggregator-informers ok
[+]poststarthook/apiservice-registration-controller ok
[+]poststarthook/apiservice-status-available-controller ok
[+]poststarthook/kube-apiserver-autoregistration ok
[+]autoregister-completion ok
[+]poststarthook/apiservice-openapi-controller ok
[+]shutdown ok
healthz check passed
```

## Individual health checks

FEATURE STATE: Kubernetes v1.30 [alpha]

Each individual health check exposes an HTTP endpoint and can be checked individually. The schema for the individual health checks is `/livez/<healthcheck-name>` or `/readyz/<healthcheck-name>`, where `livez` and `readyz` can be used to indicate if you want to check the liveness or the readiness of the API server, respectively. The `<healthcheck-name>` path can be discovered using the `verbose` flag from above and take the path between `[+]` and `ok`. These individual health checks should not be consumed by machines but can be helpful for a human operator to debug a system:

```
curl -k https://localhost:6443/livez/etcd
```

## API Access Control

For an introduction to how Kubernetes implements and controls API access, read [Controlling Access to the Kubernetes API](#).

# Authenticating

This page provides an overview of authentication.

## Users in Kubernetes

All Kubernetes clusters have two categories of users: service accounts managed by Kubernetes, and normal users.

It is assumed that a cluster-independent service manages normal users in the following ways:

- an administrator distributing private keys
- a user store like Keystone or Google Accounts
- a file with a list of usernames and passwords

In this regard, *Kubernetes does not have objects which represent normal user accounts*. Normal users cannot be added to a cluster through an API call.

Even though a normal user cannot be added via an API call, any user that presents a valid certificate signed by the cluster's certificate authority (CA) is considered authenticated. In this configuration, Kubernetes determines the username from the common name field in the 'subject' of the cert (e.g., "/CN=bob"). From there, the role based access control (RBAC) sub-system would determine whether the user is authorized to perform a specific operation on a resource. For more details, refer to the normal users topic in [certificate request](#) for more details about this.

In contrast, service accounts are users managed by the Kubernetes API. They are bound to specific namespaces, and created automatically by the API server or manually through API calls. Service accounts are tied to a set of credentials stored as Secrets, which are mounted into pods allowing in-cluster processes to talk to the Kubernetes API.

API requests are tied to either a normal user or a service account, or are treated as [anonymous requests](#). This means every process inside or outside the cluster, from a human user typing kubectl on a workstation, to kubelets on nodes, to members of the control plane, must authenticate when making requests to the API server, or be treated as an anonymous user.

# Authentication strategies

Kubernetes uses client certificates, bearer tokens, or an authenticating proxy to authenticate API requests through authentication plugins. As HTTP requests are made to the API server, plugins attempt to associate the following attributes with the request:

- Username: a string which identifies the end user. Common values might be kube-admin or jane@example.com.
- UID: a string which identifies the end user and attempts to be more consistent and unique than username.
- Groups: a set of strings, each of which indicates the user's membership in a named logical collection of users. Common values might be system:masters or devops-team.
- Extra fields: a map of strings to list of strings which holds additional information authorizers may find useful.

All values are opaque to the authentication system and only hold significance when interpreted by an [authorizer](#).

You can enable multiple authentication methods at once. You should usually use at least two methods:

- service account tokens for service accounts
- at least one other method for user authentication.

When multiple authenticator modules are enabled, the first module to successfully authenticate the request short-circuits evaluation. The API server does not guarantee the order authenticators run in.

The `system:authenticated` group is included in the list of groups for all authenticated users.

Integrations with other authentication protocols (LDAP, SAML, Kerberos, alternate x509 schemes, etc) can be accomplished using an [authenticating proxy](#) or the [authentication webhook](#).

## X509 client certificates

Client certificate authentication is enabled by passing the `--client-ca-file=SOMEFILE` option to API server. The referenced file must contain one or more certificate authorities to use to validate client certificates presented to the API server. If a client certificate is presented and verified, the common name of the subject is used as the user name for the request. As of Kubernetes 1.4, client certificates can also indicate a user's group memberships using the certificate's organization fields. To include multiple group memberships for a user, include multiple organization fields in the certificate.

For example, using the openssl command line tool to generate a certificate signing request:

```
openssl req -new -key jbeda.pem -out jbeda-csr.pem -subj "/CN=jbeda/O=app1/O=app2"
```

This would create a CSR for the username "jbeda", belonging to two groups, "app1" and "app2".

See [Managing Certificates](#) for how to generate a client cert.

## Static token file

The API server reads bearer tokens from a file when given the `--token-auth-file=SOMEFILE` option on the command line. Currently, tokens last indefinitely, and the token list cannot be changed without restarting the API server.

The token file is a csv file with a minimum of 3 columns: token, user name, user uid, followed by optional group names.

### Note:

If you have more than one group the column must be double quoted e.g.

```
token,user,uid,"group1,group2,group3"
```

## Putting a bearer token in a request

When using bearer token authentication from an http client, the API server expects an Authorization header with a value of Bearer <token>. The bearer token must be a character sequence that can be put in an HTTP header value using no more than the encoding and quoting facilities of HTTP. For example: if the bearer token is 31ada4fd-adec-460c-809a-9e56ceb75269 then it would appear in an HTTP header as shown below.

```
Authorization: Bearer 31ada4fd-adec-460c-809a-9e56ceb75269
```

## Bootstrap tokens

FEATURE STATE: Kubernetes v1.18 [stable]

To allow for streamlined bootstrapping for new clusters, Kubernetes includes a dynamically-managed Bearer token type called a *Bootstrap Token*. These tokens are stored as Secrets in the kube-system namespace, where they can be dynamically managed and created. Controller Manager contains a TokenCleaner controller that deletes bootstrap tokens as they expire.

The tokens are of the form [a-z0-9]{6}.[a-z0-9]{16}. The first component is a Token ID and the second component is the Token Secret. You specify the token in an HTTP header as follows:

```
Authorization: Bearer 781292.db7bc3a58fc5f07e
```

You must enable the Bootstrap Token Authenticator with the `--enable-bootstrap-token-auth` flag on the API Server. You must enable the TokenCleaner controller via the `--controllers` flag on the Controller Manager. This is done with something like `--controllers=*,tokencleaner`. kubeadm will do this for you if you are using it to bootstrap a cluster.

The authenticator authenticates as `system:bootstrap:<Token ID>`. It is included in the `system:bootstrappers` group. The naming and groups are intentionally limited to discourage users from using these tokens past bootstrapping. The user names and group can be used (and are used by kubeadm) to craft the appropriate authorization policies to support bootstrapping a cluster.

Please see [Bootstrap Tokens](#) for in depth documentation on the Bootstrap Token authenticator and controllers along with how to manage these tokens with kubeadm.

## Service account tokens

A service account is an automatically enabled authenticator that uses signed bearer tokens to verify requests. The plugin takes two optional flags:

- `--service-account-key-file` File containing PEM-encoded x509 RSA or ECDSA private or public keys, used to verify ServiceAccount tokens. The specified file can contain multiple keys, and the flag can be specified multiple times with different files. If unspecified, `--tls-private-key-file` is used.
- `--service-account-lookup` If enabled, tokens which are deleted from the API will be revoked.

Service accounts are usually created automatically by the API server and associated with pods running in the cluster through the ServiceAccount [Admission Controller](#). Bearer tokens are mounted into pods at well-known locations, and allow in-cluster processes to talk to the API server. Accounts may be explicitly associated with pods using the `serviceAccountName` field of a PodSpec.

### Note:

`serviceAccountName` is usually omitted because this is done automatically.

```
apiVersion: apps/v1 # this apiVersion is relevant as of Kubernetes 1.9
kind: Deployment
metadata:
 name: nginx-deployment
 namespace: default
spec:
 replicas: 3
 template:
 metadata:
 # ...
 spec:
 serviceAccountName: bob-the-bot
 containers:
 - name: nginx
 image: nginx:1.14.2
```

Service account bearer tokens are perfectly valid to use outside the cluster and can be used to create identities for long standing jobs that wish to talk to the Kubernetes API. To manually create a service account, use the `kubectl create serviceaccount (NAME)` command. This creates a service account in the current namespace.

```
kubectl create serviceaccount jenkins
```

```
serviceaccount/jenkins created
```

Create an associated token:

```
kubectl create token jenkins
```

```
eyJhbGciOiJSUzI1NiIsImtp...
```

The created token is a signed JSON Web Token (JWT).

The signed JWT can be used as a bearer token to authenticate as the given service account. See [above](#) for how the token is included in a request. Normally these tokens are mounted into pods for in-cluster access to the API server, but can be used from outside the cluster as well.

Service accounts authenticate with the username `system:serviceaccount:(NAMESPACE):(SERVICEACCOUNT)`, and are assigned to the groups `system:serviceaccounts` and `system:serviceaccounts:(NAMESPACE)`.

### Warning:

Because service account tokens can also be stored in Secret API objects, any user with write access to Secrets can request a token, and any user with read access to those Secrets can authenticate as the service account. Be cautious when granting permissions to service accounts and read or write capabilities for Secrets.

## OpenID Connect Tokens

[OpenID Connect](#) is a flavor of OAuth2 supported by some OAuth2 providers, notably Microsoft Entra ID, Salesforce, and Google. The protocol's main extension of OAuth2 is an additional field returned with the access token called an [ID Token](#). This token is a JSON Web Token (JWT) with well known fields, such as a user's email, signed by the server.

To identify the user, the authenticator uses the `id_token` (not the `access_token`) from the OAuth2 [token response](#) as a bearer token. See [above](#) for how the token is included in a request.

```
sequenceDiagram
 participant user as User

*JavaScript must be [enabled](#) to view this content*

1. Log in to your identity provider
2. Your identity provider will provide you with an `access_token`, `id_token` and a `refresh_token`
3. When using `kubectl`, use your `id_token` with the `--token` flag or add it directly to your `kubeconfig`
4. `kubectl` sends your `id_token` in a header called `Authorization` to the API server
5. The API server will make sure the JWT signature is valid
6. Check to make sure the `id_token` hasn't expired
  1. Perform claim and/or user validation if CEL expressions are configured with `AuthenticationConfiguration`.
7. Make sure the user is authorized
8. Once authorized the API server returns a response to `kubectl`
9. `kubectl` provides feedback to the user

Since all of the data needed to validate who you are is in the `id_token`, Kubernetes doesn't need to "phone home" to the identity provider. In a model where every request is stateless this provides a very scalable solution for authentication. It does offer a few challenges:

1. Kubernetes has no "web interface" to trigger the authentication process. There is no browser or interface to collect credentials which is why you need to authenticate to your identity provider first.
2. The `id_token` can't be revoked, it's like a certificate so it should be short-lived (only a few minutes) so it can be very annoying to have to get a new token every few minutes.
3. To authenticate to the Kubernetes dashboard, you must use the `kubectl proxy` command or a reverse proxy that injects the `id_token`.

## Configuring the API Server

### Using flags

To enable the plugin, configure the following flags on the API server:

| Parameter                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Example                                                                                                                                                                                    | Required |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|
| <code>--oidc-issuer-url</code>      | URL of the provider that allows the API server to discover public signing keys. Only URLs that use the <code>https://</code> scheme are accepted. This is typically the provider's discovery URL, changed to have an empty path                                                                                                                                                                                                                                                                                         | If the issuer's OIDC discovery URL is <code>https://accounts.provider.example/.well-known/openid-configuration</code> , the value should be <code>https://accounts.provider.example</code> | Yes      |
| <code>--oidc-client-id</code>       | A client id that all tokens must be issued for.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | kubernetes                                                                                                                                                                                 | Yes      |
| <code>--oidc-username-claim</code>  | JWT claim to use as the user name. By default <code>sub</code> , which is expected to be a unique identifier of the end user. Admins can choose other claims, such as email or name, depending on their provider. However, claims other than email will be prefixed with the issuer URL to prevent naming clashes with other plugins.                                                                                                                                                                                   | <code>sub</code>                                                                                                                                                                           | No       |
| <code>--oidc-username-prefix</code> | Prefix prepended to username claims to prevent clashes with existing names (such as <code>system:users</code> ). For example, the value <code>oidc:</code> will create usernames like <code>oidc:jane.doe</code> . If this flag isn't provided and <code>--oidc-username-claim</code> is a value other than email the prefix defaults to <code>( Issuer URL )#</code> where <code>( Issuer URL )</code> is the value of <code>--oidc-issuer-url</code> . The value <code>-</code> can be used to disable all prefixing. | <code>oidc:</code>                                                                                                                                                                         | No       |

| Parameter                          | Description                                                                                                                                                                                                                          | Example                       | Required |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|----------|
| <code>--oidc-groups-claim</code>   | JWT claim to use as the user's group. If the claim is present it must be an array of strings.                                                                                                                                        | groups                        | No       |
| <code>--oidc-groups-prefix</code>  | Prefix prepended to group claims to prevent clashes with existing names (such as system: groups). For example, the value <code>oidc:</code> will create group names like <code>oidc:engineering</code> and <code>oidc:infra</code> . | oidc:                         | No       |
| <code>--oidc-required-claim</code> | A key=value pair that describes a required claim in the ID Token. If set, the claim is verified to be present in the ID Token with a matching value. Repeat this flag to specify multiple claims.                                    | claim=value                   | No       |
| <code>--oidc-ca-file</code>        | The path to the certificate for the CA that signed your identity provider's web certificate. Defaults to the host's root CAs.                                                                                                        | /etc/kubernetes/ssl/kc-ca.pem | No       |
| <code>--oidc-signing-algs</code>   | The signing algorithms accepted. Default is "RS256".                                                                                                                                                                                 | RS512                         | No       |

#### Authentication configuration from a file

FEATURE STATE: Kubernetes v1.30 [beta]

JWT Authenticator is an authenticator to authenticate Kubernetes users using JWT compliant tokens. The authenticator will attempt to parse a raw ID token, verify it's been signed by the configured issuer. The public key to verify the signature is discovered from the issuer's public endpoint using OIDC discovery.

The minimum valid JWT payload must contain the following claims:

```
{
 "iss": "https://example.com", // must match the issuer.url
 "aud": ["my-app"], // at least one of the entries in issuer.audiences must match the
 // "aud" claim in presented JWTs.
 "exp": 1234567890, // token expiration as Unix time (the number of seconds elapsed
 // since January 1, 1970 UTC)
 "<username-claim>": "user" // this is the username claim configured in the
 // claimMappings.username.claim or claimMappings.username.expression
}
```

The configuration file approach allows you to configure multiple JWT authenticators, each with a unique issuer.url and issuer.discoveryURL. The configuration file even allows you to specify [CEL](#) expressions to map claims to user attributes, and to validate claims and user information. The API server also automatically reloads the authenticators when the configuration file is modified. You can use `apiserver_authentication_config_controller_automatic_reload_last_timestamp_seconds` metric to monitor the last time the configuration was reloaded by the API server.

You must specify the path to the authentication configuration using the `--authentication-config` flag on the API server. If you want to use command line flags instead of the configuration file, those will continue to work as-is. To access the new capabilities like configuring multiple authenticators, setting multiple audiences for an issuer, switch to using the configuration file.

For Kubernetes v1.30, the structured authentication configuration file format is beta-level, and the mechanism for using that configuration is also beta. Provided you didn't specifically disable the StructuredAuthenticationConfiguration [feature gate](#) for your cluster, you can turn on structured authentication by specifying the `--authentication-config` command line argument to the kube-apiserver. An example of the structured authentication configuration file is shown below.

#### Note:

If you specify `--authentication-config` along with any of the `--oidc-*` command line arguments, this is a misconfiguration. In this situation, the API server reports an error and then immediately exits. If you want to switch to using structured authentication configuration, you have to remove the `--oidc-*` command line arguments, and use the configuration file instead.

```

#
CAUTION: this is an example configuration.
Do not use this for your own cluster!
#
apiVersion: apiserver.config.k8s.io/v1beta1
kind: AuthenticationConfiguration
list of authenticators to authenticate Kubernetes users using JWT compliant tokens.
the maximum number of allowed authenticators is 64.
jwt:
- issuer:
 # url must be unique across all authenticators.
 # url must not conflict with issuer configured in --service-account-issuer.
 url: https://example.com # Same as --oidc-issuer-url.
 # discoveryURL, if specified, overrides the URL used to fetch discovery
 # information instead of using "{url}/.well-known/openid-configuration".
 # The exact value specified is used, so "/.well-known/openid-configuration"
 # must be included in discoveryURL if needed.
 #
 # The "issuer" field in the fetched discovery information must match the "issuer.url" field
 # in the AuthenticationConfiguration and will be used to validate the "iss" claim in the
presented JWT.
 # This is for scenarios where the well-known and jwks endpoints are hosted at a different
 # location than the issuer (such as locally in the cluster).
 # discoveryURL must be different from url if specified and must be unique across all
authenticators.
 discoveryURL: https://discovery.example.com/.well-known/openid-configuration
 # PEM encoded CA certificates used to validate the connection when fetching
 # discovery information. If not set, the system verifier will be used.
 # Same value as the content of the file referenced by the --oidc-ca-file flag.
 certificateAuthority: <PEM encoded CA certificates>
 # audiences is the set of acceptable audiences the JWT must be issued to.
 # At least one of the entries must match the "aud" claim in presented JWTs.
 audiences:
```

- my-app # Same as --oidc-client-id.
- my-other-app
- # this is required to be set to "MatchAny" when multiple audiences are specified.
- audienceMatchPolicy: MatchAny
- # rules applied to validate token claims to authenticate users.
- claimValidationRules:
  - # Same as --oidc-required-claim key=value.
- claim: hd
  - requiredValue: example.com
  - # Instead of claim and requiredValue, you can use expression to validate the claim.
  - # expression is a CEL expression that evaluates to a boolean.
  - # all the expressions must evaluate to true for validation to succeed.
- expression: 'claims.hd == "example.com"'
  - # Message customizes the error message seen in the API server logs when the validation fails.
  - message: the hd claim must be set to example.com
- expression: 'claims.exp - claims.nbf <= 86400'
  - message: total token lifetime must not exceed 24 hours
- claimMappings:
  - # username represents an option for the username attribute.
  - # This is the only required attribute.
  - username:
    - # Same as --oidc-username-claim. Mutually exclusive with username.expression.
    - claim: "sub"
    - # Same as --oidc-username-prefix. Mutually exclusive with username.expression.
    - # if username.claim is set, username.prefix is required.
    - # Explicitly set it to "" if no prefix is desired.
    - prefix: ""
    - # Mutually exclusive with username.claim and username.prefix.
    - # expression is a CEL expression that evaluates to a string.
    - #
    - # 1. If username.expression uses 'claims.email', then 'claims.email\_verified' must be used in username.expression or extra[\*].valueExpression or claimValidationRules[\*].expression.
    - # An example claim validation rule expression that matches the validation automatically applied when username.claim is set to 'email' is 'claims.?email\_verified.orValue(true)'.
    - # 2. If the username asserted based on username.expression is the empty string, the
- authentication
  - # request will fail.
  - expression: 'claims.username + ":external-user"'
  - # groups represents an option for the groups attribute.
  - groups:
    - # Same as --oidc-groups-claim. Mutually exclusive with groups.expression.
    - claim: "sub"
    - # Same as --oidc-groups-prefix. Mutually exclusive with groups.expression.
    - # if groups.claim is set, groups.prefix is required.
    - # Explicitly set it to "" if no prefix is desired.
    - prefix: ""
    - # Mutually exclusive with groups.claim and groups.prefix.
    - # expression is a CEL expression that evaluates to a string or a list of strings.
    - expression: 'claims.roles.split(",")'
  - # uid represents an option for the uid attribute.
  - uid:
    - # Mutually exclusive with uid.expression.
    - claim: 'sub'

```

Mutually exclusive with uid.claim
expression is a CEL expression that evaluates to a string.
expression: 'claims.sub'
extra attributes to be added to the UserInfo object. Keys must be domain-prefix path and
must be unique.
extra:
- key: 'example.com/tenant'
 # valueExpression is a CEL expression that evaluates to a string or a list of strings.
 valueExpression: 'claims.tenant'
validation rules applied to the final user object.
userValidationRules:
expression is a CEL expression that evaluates to a boolean.
all the expressions must evaluate to true for the user to be valid.
- expression: "!user.username.startsWith('system:')"
Message customizes the error message seen in the API server logs when the validation fails.
message: 'username cannot used reserved system: prefix'
- expression: "user.groups.all(group, !group.startsWith('system:'))"
message: 'groups cannot used reserved system: prefix'

```

- Claim validation rule expression

`jwt.claimValidationRules[i].expression` represents the expression which will be evaluated by CEL. CEL expressions have access to the contents of the token payload, organized into claims CEL variable. `claims` is a map of claim names (as strings) to claim values (of any type).

- User validation rule expression

`jwt.userValidationRules[i].expression` represents the expression which will be evaluated by CEL. CEL expressions have access to the contents of `userInfo`, organized into user CEL variable. Refer to the [UserInfo](#) API documentation for the schema of user.

- Claim mapping expression

`jwt.claimMappings.username.expression`, `jwt.claimMappings.groups.expression`, `jwt.claimMappings.uid.expression` `jwt.claimMappings.extra[i].valueExpression` represents the expression which will be evaluated by CEL. CEL expressions have access to the contents of the token payload, organized into claims CEL variable. `claims` is a map of claim names (as strings) to claim values (of any type).

To learn more, see the [Documentation on CEL](#)

Here are examples of the `AuthenticationConfiguration` with different token payloads.

and expression will evaluate to false, so validation will fail.
 message: 'username cannot used reserved system: prefix'
```

TOKEN=eyJhbGciOiJSUzI1NiIsImtpZCI6ImY3dF9tOEROWmFTQk1oWGW5QXZTWGhBUC04Y0JmZ0JVbFVpTG5oQkgxdXMiLCJ0eXAiOiJKV1QiQifQ.eyJhdWQiOiJrdWJlcm5ldGVzLiwiaXhwIjoxNzAzMjMyOTQ5LCJoZCI6ImV4YW1wbGUuY29tIiwiaWF0IjoxNzAxMTEzMjA5MTA5LCJpc3MiOiJodHRwczovL2V4YW1wbGUuY29tIiwianRpIjoieyJyViMDY1MjM3MmNmMjBlMzQ1YjZmZGZmY2RjMjE4MWY0YWZkNmYyNTlhYW10YjdlMzU4ODEyMzdKmjkyMjBiYyIsIm5iZil6MTcwMTExMzEwMSwicm9sZXMiOiJ1c2VyLGFKbWluIiwic3ViIjoieXV0aCIsInRlbmFudCI6IjcyZjk4OGJmLTg2ZjEtNDZhZi05MWFhLTIjkn2NkMDExZW50YSIsbnVzZXJuYW1lIjoieyJmZm9vIn0.fgPJBYLobo9jnbHreooBlvpgeEcSPWnKfX6dc0IvdLRBF0dCcgy91oCJeK\_aBk-8zh5AKUXoFTllnfLckPivMOJqMECA1YTrMUwt\_IVqwb116AqihfByUYIIqzmjvUbthtbpleHQm2ff0HbrUqa\_Q0uaYwgy8mD807h7sBcUMjNd215ff\_nFIHss-9zegH8GI1d9fiBf-g6zjkr1j987EP748khpqh9IxPjMJbsgg\_uH5x80YFuqgEWwq-aYJPQxxX6FatP96a2EAan7wfppGlPrT0HcBOvq5pCnudgcgfvgiojiLr\_7robQu4T1bis0W75VPEvwWtgFcLnvcOx0JWg

where the token payload is:

```
{
 "aud": "kubernetes",
 "exp": 1703232949,
 "hd": "example.com",
 "iat": 1701113101,
 "iss": "https://example.com",
 "jti": "b5b0652372cd20e345b6fdffcdc2181f4afd6f259aab4b7e35881237d29220bc",
 "nbf": 1701113101,
 "roles": "user,admin",
 "sub": "auth",
 "tenant": "72f988bf-86f1-41af-91ab-2d7cd011db4a",
 "username": "foo"
}
```

The token with the above AuthenticationConfiguration will produce the following UserInfo object:

```
{
 "username": "system:foo",
 "uid": "auth",
 "groups": [
 "user",
 "admin"
],
 "extra": {
 "example.com/tenant": "72f988bf-86f1-41af-91ab-2d7cd011db4a"
 }
}
```

which will fail user validation because the username starts with `system:`. The API server will return 401 Unauthorized error.

#### Limitations

1. Distributed claims do not work via [CEL](#) expressions.
2. Egress selector configuration is not supported for calls to `issuer.url` and `issuer.discoveryURL`.

Kubernetes does not provide an OpenID Connect Identity Provider. You can use an existing public OpenID Connect Identity Provider (such as Google, or [others](#)). Or, you can run your own Identity Provider, such as [dex](#), [Keycloak](#), CloudFoundry [UAA](#), or Tremolo Security's [OpenUnison](#).

For an identity provider to work with Kubernetes it must:

1. Support [OpenID connect discovery](#)

The public key to verify the signature is discovered from the issuer's public endpoint using OIDC discovery. If you're using the authentication configuration file, the identity provider doesn't need to publicly expose the discovery endpoint. You can host the

discovery endpoint at a different location than the issuer (such as locally in the cluster) and specify the issuer.discoveryURL in the configuration file.

2. Run in TLS with non-obsolete ciphers

3. Have a CA signed certificate (even if the CA is not a commercial CA or is self signed)

A note about requirement #3 above, requiring a CA signed certificate. If you deploy your own identity provider (as opposed to one of the cloud providers like Google or Microsoft) you **MUST** have your identity provider's web server certificate signed by a certificate with the CA flag set to TRUE, even if it is self signed. This is due to GoLang's TLS client implementation being very strict to the standards around certificate validation. If you don't have a CA handy, you can use the [gencert script](#) from the Dex team to create a simple CA and a signed certificate and key pair. Or you can use [this similar script](#) that generates SHA256 certs with a longer life and larger key size.

Setup instructions for specific systems:

- [UAA](#)
- [Dex](#)
- [OpenUnison](#)

## Using kubectl

### Option 1 - OIDC Authenticator

The first option is to use the kubectl oidc authenticator, which sets the id\_token as a bearer token for all requests and refreshes the token once it expires. After you've logged into your provider, use kubectl to add your id\_token, refresh\_token, client\_id, and client\_secret to configure the plugin.

Providers that don't return an id\_token as part of their refresh token response aren't supported by this plugin and should use "Option 2" below.

```
kubectl config set-credentials USER_NAME \
--auth-provider=oidc \
--auth-provider-arg=idp-issuer-url=(issuer url) \
--auth-provider-arg=client-id=(your client id) \
--auth-provider-arg=client-secret=(your client secret) \
--auth-provider-arg=refresh-token=(your refresh token) \
--auth-provider-arg=idp-certificate-authority=(path to your ca certificate) \
--auth-provider-arg=id-token=(your id_token)
```

As an example, running the below command after authenticating to your identity provider:

```
kubectl config set-credentials mmosley \
--auth-provider=oidc \
--auth-provider-arg=idp-issuer-url=https://oidcidp.tremolo.lan:8443/auth/idp/OidcIdP \
--auth-provider-arg=client-id=kubernetes \
--auth-provider-arg=client-secret=1db158f6-177d-4d9c-8a8b-d36869918ec5 \
--auth-provider-arg=refresh-token=q1bKLFOyUiosTfawzA93TzZIDzH2TNa2SMm0zEiPKT
UwME6BkEo6Sql5yUWVBSWpKUGphaWpxSVAfekBOZbBhaEW+VIFUeVRGcluyVF5JT4+haZ
mPsluFoFu5XkpXk5BXqHega4GAXlF+ma+vmYpFcHe5eZR+slBFpZKtQA= \

```

```
--auth-provider-arg=idp-certificate-authority=/root/ca.pem \
--auth-provider-arg=id-token=eyJraWQiOiJDTj1vaWRjaWRwLnRyZW1vbG8ubGFuLCBPVT1EZW1vLCBPPVRybWVvbG8gU2VjdXJpdHksIEw9QXJsaW5ndG9uLCBTVD1WaXJnaW5pYSwgQz1VUy1DTj1rdWJlLWNhLTEyMDIxNDc5MjEwMzYwNzMyMTUyIiwiaWF0IjoiUlMyNTYifQ.eyJpc3MiOiJodHRwczovL29pZG9pZHAudHJlbW9sby5sYW46ODQ0My9hdXRoL2lkC9PaWRjSWRQIiwiaXVkJjoia3ViZXJuZXRlcyIsImV4cCI6MTQ4MzU0OTUxMSwianRpIjoiaMm96US15TXdFcHV4WDIHZUhQdy1hZyIsImhhdCI6MTQ4MzU0OTQ1MSwibmJmIjoxNDgzNTQ5MzMxLCJzdWIiOiI0YWViMzdiYS1iNjQ1LTQ4ZmQtYWZlMC0xYTAxZWU0MWUyMTgifQ.w6p4J_6qQ1HzTG9nrEOrubxIMb9K5hzcMPxc9IxPx2K4xO9l-oFiUw93daH3m5pluP6K7eOE6txBuRVfEcpJSwlelsOsW8gb8VJcnzMS9EnZpeA0tW_p-mnkFc3VcfyXuhe5R3G7aa5d8uHv70yJ9Y3-UhjiN9EhpMdfPAoEB9fYKKkJRzF7utTTIPGrSaSU6d2pcpfYKaxIwePzEkT4DfcQthoZdy9ucNvvLoi1DIC-UocFD8HLs8LYKEqSxQvOcvnThbObJ9af71EwmuE21fO5KzMW20KtAeget1gnldOosPtz1G5EwvaQ401-RPQzPGMVBld0_zMCAwZttJ4knw
```

Which would produce the below configuration:

```
users:
- name: mmosley
 user:
 auth-provider:
 config:
 client-id: kubernetes
 client-secret: 1db158f6-177d-4d9c-8a8b-d36869918ec5
 id-token: eyJraWQiOiJDTj1vaWRjaWRwLnRyZW1vbG8ubGFuLCBPPVT1EZW1vLCBPPVRybWVvbG8gU2VjdXJpdHksIEw9QXJsaW5ndG9uLCBTVD1WaXJnaW5pYSwgQz1VUy1DTj1rdWJlLWNhLTEyMDIxNDc5MjEwMzYwNzMyMTUyIiwiaWF0IjoiUlMyNTYifQ.eyJpc3MiOiJodHRwczovL29pZG9pZHAudHJlbW9sby5sYW46ODQ0My9hdXRoL2lkC9PaWRjSWRQIiwiaXVkJjoia3ViZXJuZXRlcyIsImV4cCI6MTQ4MzU0OTUxMSwianRpIjoiaMm96US15TXdFcHV4WDIHZUhQdy1hZyIsImhhdCI6MTQ4MzU0OTQ1MSwibmJmIjoxNDgzNTQ5MzMxLCJzdWIiOiI0YWViMzdiYS1iNjQ1LTQ4ZmQtYWZlMC0xYTAxZWU0MWUyMTgifQ.w6p4J_6qQ1HzTG9nrEOrubxIMb9K5hzcMPxc9IxPx2K4xO9l-oFiUw93daH3m5pluP6K7eOE6txBuRVfEcpJSwlelsOsW8gb8VJcnzMS9EnZpeA0tW_p-mnkFc3VcfyXuhe5R3G7aa5d8uHv70yJ9Y3-UhjiN9EhpMdfPAoEB9fYKKkJRzF7utTTIPGrSaSU6d2pcpfYKaxIwePzEkT4DfcQthoZdy9ucNvvLoi1DIC-UocFD8HLs8LYKEqSxQvOcvnThbObJ9af71EwmuE21fO5KzMW20KtAeget1gnldOosPtz1G5EwvaQ401-RPQzPGMVBld0_zMCAwZttJ4knw
 idp-certificate-authority: /root/ca.pem
 idp-issuer-url: https://oidcidp.tremolo.lan:8443/auth/idp/OidcIdP
 refresh-token: q1bKLFOyUiosTfawzA93TzZIDzH2TNa2SMm0zEiPKTUwME6BkEo6Sql5yUWVBSWpKUGphaWpxSVAfekBOZbBhaEW+VIFUeVRGcluyVF5JT4+haZmPsluFoFu5XkpXk5BXq
 name: oidc
```

Once your `id_token` expires, `kubectl` will attempt to refresh your `id_token` using your `refresh_token` and `client_secret` storing the new values for the `refresh_token` and `id_token` in your `.kube/config`.

## Option 2 - Use the --token Option

The `kubectl` command lets you pass in a token using the `--token` option. Copy and paste the `id_token` into this option:

```
kubectl --token=eyJhbGciOiJSUzI1NiJ9.eyJpc3MiOiJodHRwczovL21sYi50cmVtb2xvLmxhbjo4MDQzL2F1dGgvaWRwL29pZGMiLCJhdWQiOiJrdWJlcm5ldGVzliwiZXhwIjoxNDc0NTk2NjY5LCJqdGkiOiI2RDUzNXoxUEpFNjJlbnR3QXaWVYIm9RliwiaWF0IjoxNDc0NTk2MzY5LCJmYmYiOiE0NzQ1OTYyNDksInN1YiI6Im13aW5kdSIsInVzZXJfcm9sZSI6WyJ1c2VycyIsIm5ldy1uYW1lc3BhY2Utdmld2VyIl0sImVtYWlsIjoibXdpbmR1QG5vbW9yZWplZGkuY29tIn0.f2As579n9VNoaKzoF-dOQGmXkFKf1FMyNV0-va_B63jn-_n9LGSCca_6IVMP8pO-Zb4KvRqGyTP0r3HkHxYy5c81Anlh8ijarruczl-TK_yF5akjSTHFZD-0gRzlevBDiH8Q79NAr-ky0P4iIXS8lY9Vnjch5MF74Zx0c3alKJHJUnnpjIACByfF2SCaYzbWFMUNat-K1PaUk5-ujMBG7yYnr95xD-63n8CO8teGUAaEMx6zRjzfhnhbzX-ajwZLGwGUBT4WqjMs70-6a7_8gZmLZb2az1cZynkFRj2BaCkVT3A2RrjeEwZEtGXlMqKJ1_I2ulrOVsYx01_yD35-rw get nodes
```

## Webhook Token Authentication

Webhook authentication is a hook for verifying bearer tokens.

- `--authentication-token-webhook-config-file` a configuration file describing how to access the remote webhook service.
- `--authentication-token-webhook-cache-ttl` how long to cache authentication decisions. Defaults to two minutes.
- `--authentication-token-webhook-version` determines whether to use `authentication.k8s.io/v1beta1` or `authentication.k8s.io/v1` `TokenReview` objects to send/receive information from the webhook. Defaults to `v1beta1`.

The configuration file uses the [kubernetes config](#) file format. Within the file, `clusters` refers to the remote service and `users` refers to the API server webhook. An example would be:

```
Kubernetes API version
apiVersion: v1
kind of the API object
kind: Config
clusters refers to the remote service.
clusters:
- name: name-of-remote-authn-service
 cluster:
 certificate-authority: /path/to/ca.pem # CA for verifying the remote service.
 server: https://authn.example.com/authenticate # URL of remote service to query. 'https'
recommended for production.

users refers to the API server's webhook configuration.
users:
- name: name-of-api-server
 user:
 client-certificate: /path/to/cert.pem # cert for the webhook plugin to use
 client-key: /path/to/key.pem # key matching the cert

kubeconfig files require a context. Provide one for the API server.
current-context: webhook
```

```
contexts:
- context:
 cluster: name-of-remote-authn-service
 user: name-of-api-server
 name: webhook
```

When a client attempts to authenticate with the API server using a bearer token as discussed [above](#), the authentication webhook POSTs a JSON-serialized TokenReview object containing the token to the remote service.

Note that webhook API objects are subject to the same [versioning compatibility rules](#) as other Kubernetes API objects. Implementers should check the `apiVersion` field of the request to ensure correct deserialization, and **must** respond with a TokenReview object of the same version as the request.

- [authentication.k8s.io/v1](#)
- [authentication.k8s.io/v1beta1](#)

#### Note:

The Kubernetes API server defaults to sending `authentication.k8s.io/v1beta1` token reviews for backwards compatibility. To opt into receiving `authentication.k8s.io/v1` token reviews, the API server must be started with `--authentication-token-webhook-version=v1`.

```
{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "TokenReview",
 "spec": {
 # Opaque bearer token sent to the API server
 "token": "014fbff9a07c...",

 # Optional list of the audience identifiers for the server the token was presented to.
 # Audience-aware token authenticators (for example, OIDC token authenticators)
 # should verify the token was intended for at least one of the audiences in this list,
 # and return the intersection of this list and the valid audiences for the token in the response
 status.
 # This ensures the token is valid to authenticate to the server it was presented to.
 # If no audiences are provided, the token should be validated to authenticate to the
 Kubernetes API server.
 "audiences": ["https://myserver.example.com", "https://myserver.internal.example.com"]
 }
}
```

```
{
 "apiVersion": "authentication.k8s.io/v1beta1",
 "kind": "TokenReview",
 "spec": {
 # Opaque bearer token sent to the API server
 "token": "014fbff9a07c...",

 # Optional list of the audience identifiers for the server the token was presented to.
 # Audience-aware token authenticators (for example, OIDC token authenticators)
 # should verify the token was intended for at least one of the audiences in this list,
```

```

and return the intersection of this list and the valid audiences for the token in the response
status.
This ensures the token is valid to authenticate to the server it was presented to.
If no audiences are provided, the token should be validated to authenticate to the
Kubernetes API server.
"audiences": ["https://myserver.example.com", "https://myserver.internal.example.com"]
}
}

```

The remote service is expected to fill the status field of the request to indicate the success of the login. The response body's spec field is ignored and may be omitted. The remote service must return a response using the same TokenReview API version that it received. A successful validation of the bearer token would return:

- [authentication.k8s.io/v1](https://kubernetes.io/api/authentication.k8s.io/v1)
- [authentication.k8s.io/v1beta1](https://kubernetes.io/api/authentication.k8s.io/v1beta1)

```

{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "TokenReview",
 "status": {
 "authenticated": true,
 "user": {
 # Required
 "username": "janedoe@example.com",
 # Optional
 "uid": "42",
 # Optional group memberships
 "groups": ["developers", "qa"],
 # Optional additional information provided by the authenticator.
 # This should not contain confidential data, as it can be recorded in logs
 # or API objects, and is made available to admission webhooks.
 "extra": {
 "extrafield1": [
 "extravalue1",
 "extravalue2"
]
 }
 },
 # Optional list audience-aware token authenticators can return,
 # containing the audiences from the `spec.audiences` list for which the provided token was
 valid.
 # If this is omitted, the token is considered to be valid to authenticate to the Kubernetes API
 server.
 "audiences": ["https://myserver.example.com"]
 }
}

```

```

{
 "apiVersion": "authentication.k8s.io/v1beta1",
 "kind": "TokenReview",
 "status": {
 "authenticated": true,

```

```

"user": {
 # Required
 "username": "janedoe@example.com",
 # Optional
 "uid": "42",
 # Optional group memberships
 "groups": ["developers", "qa"],
 # Optional additional information provided by the authenticator.
 # This should not contain confidential data, as it can be recorded in logs
 # or API objects, and is made available to admission webhooks.
 "extra": {
 "extrafield1": [
 "extravalue1",
 "extravalue2"
]
 }
},
Optional list audience-aware token authenticators can return,
containing the audiences from the `spec.audiences` list for which the provided token was
valid.
If this is omitted, the token is considered to be valid to authenticate to the Kubernetes API
server.
"audiences": ["https://myserver.example.com"]
}
}

```

An unsuccessful request would return:

- [authentication.k8s.io/v1](https://kubernetes.io/api/authentication.k8s.io/v1)
- [authentication.k8s.io/v1beta1](https://kubernetes.io/api/authentication.k8s.io/v1beta1)

```

{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "TokenReview",
 "status": {
 "authenticated": false,
 # Optionally include details about why authentication failed.
 # If no error is provided, the API will return a generic Unauthorized message.
 # The error field is ignored when authenticated=true.
 "error": "Credentials are expired"
 }
}

```

```

{
 "apiVersion": "authentication.k8s.io/v1beta1",
 "kind": "TokenReview",
 "status": {
 "authenticated": false,
 # Optionally include details about why authentication failed.
 # If no error is provided, the API will return a generic Unauthorized message.
 # The error field is ignored when authenticated=true.
 "error": "Credentials are expired"
 }
}

```

```
}
}
```

## Authenticating Proxy

The API server can be configured to identify users from request header values, such as X-Remote-User. It is designed for use in combination with an authenticating proxy, which sets the request header value.

- `--requestheader-username-headers` Required, case-insensitive. Header names to check, in order, for the user identity. The first header containing a value is used as the username.
- `--requestheader-group-headers` 1.6+. Optional, case-insensitive. "X-Remote-Group" is suggested. Header names to check, in order, for the user's groups. All values in all specified headers are used as group names.
- `--requestheader-extra-headers-prefix` 1.6+. Optional, case-insensitive. "X-Remote-Extra-" is suggested. Header prefixes to look for to determine extra information about the user (typically used by the configured authorization plugin). Any headers beginning with any of the specified prefixes have the prefix removed. The remainder of the header name is lowercased and [percent-decoded](#) and becomes the extra key, and the header value is the extra value.

### Note:

Prior to 1.11.3 (and 1.10.7, 1.9.11), the extra key could only contain characters which were [legal in HTTP header labels](#).

For example, with this configuration:

```
--requestheader-username-headers=X-Remote-User
--requestheader-group-headers=X-Remote-Group
--requestheader-extra-headers-prefix=X-Remote-Extra-
```

this request:

```
GET / HTTP/1.1
X-Remote-User: fido
X-Remote-Group: dogs
X-Remote-Group: dachshunds
X-Remote-Extra-Acme.com%2Fproject: some-project
X-Remote-Extra-Scopes: openid
X-Remote-Extra-Scopes: profile
```

would result in this user info:

```
name: fido
groups:
- dogs
- dachshunds
extra:
 acme.com/project:
 - some-project
scopes:
```

- openid
- profile

In order to prevent header spoofing, the authenticating proxy is required to present a valid client certificate to the API server for validation against the specified CA before the request headers are checked. WARNING: do **not** reuse a CA that is used in a different context unless you understand the risks and the mechanisms to protect the CA's usage.

- `--requestheader-client-ca-file` Required. PEM-encoded certificate bundle. A valid client certificate must be presented and validated against the certificate authorities in the specified file before the request headers are checked for user names.
- `--requestheader-allowed-names` Optional. List of Common Name values (CNs). If set, a valid client certificate with a CN in the specified list must be presented before the request headers are checked for user names. If empty, any CN is allowed.

## Anonymous requests

When enabled, requests that are not rejected by other configured authentication methods are treated as anonymous requests, and given a username of `system:anonymous` and a group of `system:unauthenticated`.

For example, on a server with token authentication configured, and anonymous access enabled, a request providing an invalid bearer token would receive a 401 Unauthorized error. A request providing no bearer token would be treated as an anonymous request.

In 1.5.1-1.5.x, anonymous access is disabled by default, and can be enabled by passing the `--anonymous-auth=true` option to the API server.

In 1.6+, anonymous access is enabled by default if an authorization mode other than `AlwaysAllow` is used, and can be disabled by passing the `--anonymous-auth=false` option to the API server. Starting in 1.6, the ABAC and RBAC authorizers require explicit authorization of the `system:anonymous` user or the `system:unauthenticated` group, so legacy policy rules that grant access to the `*` user or `*` group do not include anonymous users.

## User impersonation

A user can act as another user through impersonation headers. These let requests manually override the user info a request authenticates as. For example, an admin could use this feature to debug an authorization policy by temporarily impersonating another user and seeing if a request was denied.

Impersonation requests first authenticate as the requesting user, then switch to the impersonated user info.

- A user makes an API call with their credentials *and* impersonation headers.
- API server authenticates the user.
- API server ensures the authenticated users have impersonation privileges.
- Request user info is replaced with impersonation values.
- Request is evaluated, authorization acts on impersonated user info.

The following HTTP headers can be used to performing an impersonation request:

- `Impersonate-User`: The username to act as.

- **Impersonate-Group:** A group name to act as. Can be provided multiple times to set multiple groups. Optional. Requires "Impersonate-User".
- **Impersonate-Extra-( extra name ):** A dynamic header used to associate extra fields with the user. Optional. Requires "Impersonate-User". In order to be preserved consistently, ( extra name ) must be lower-case, and any characters which aren't [legal in HTTP header labels](#) MUST be utf8 and [percent-encoded](#).
- **Impersonate-Uid:** A unique identifier that represents the user being impersonated. Optional. Requires "Impersonate-User". Kubernetes does not impose any format requirements on this string.

**Note:**

Prior to 1.11.3 (and 1.10.7, 1.9.11), ( extra name ) could only contain characters which were [legal in HTTP header labels](#).

**Note:**

Impersonate-Uid is only available in versions 1.22.0 and higher.

An example of the impersonation headers used when impersonating a user with groups:

```
Impersonate-User: jane.doe@example.com
Impersonate-Group: developers
Impersonate-Group: admins
```

An example of the impersonation headers used when impersonating a user with a UID and extra fields:

```
Impersonate-User: jane.doe@example.com
Impersonate-Extra-dn: cn=jane,ou=engineers,dc=example,dc=com
Impersonate-Extra-acme.com%2Fproject: some-project
Impersonate-Extra-scopes: view
Impersonate-Extra-scopes: development
Impersonate-Uid: 06f6ce97-e2c5-4ab8-7ba5-7654dd08d52b
```

When using `kubectl` set the `--as` flag to configure the `Impersonate-User` header, set the `--as-group` flag to configure the `Impersonate-Group` header.

```
kubectl drain mynode
```

Error from server (Forbidden): User "clark" cannot get nodes at the cluster scope. (get nodes mynode)

Set the `--as` and `--as-group` flag:

```
kubectl drain mynode --as=superman --as-group=system:masters
```

```
node/mynode cordoned
node/mynode drained
```

**Note:**

`kubectl` cannot impersonate extra fields or UIDs.

To impersonate a user, group, user identifier (UID) or extra fields, the impersonating user must have the ability to perform the "impersonate" verb on the kind of attribute being impersonated ("user", "group", "uid", etc.). For clusters that enable the RBAC authorization plugin, the following ClusterRole encompasses the rules needed to set user and group impersonation headers:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: impersonator
rules:
- apiGroups: [""]
 resources: ["users", "groups", "serviceaccounts"]
 verbs: ["impersonate"]
```

For impersonation, extra fields and impersonated UIDs are both under the "authentication.k8s.io" apiGroup. Extra fields are evaluated as sub-resources of the resource "userextras". To allow a user to use impersonation headers for the extra field "scopes" and for UIDs, a user should be granted the following role:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: scopes-and-uid-impersonator
rules:
Can set "Impersonate-Extra-scopes" header and the "Impersonate-Uid" header.
- apiGroups: ["authentication.k8s.io"]

 verbs: ["impersonate"]
 resourceNames: ["developers", "admins"]

Can impersonate the extras field "scopes" with the values "view" and "development"
- apiGroups: ["authentication.k8s.io"]
 resources: ["userextras/scopes"]
```

```
verbs: ["impersonate"]
resourceNames: ["view", "development"]

Can impersonate the uid "06f6ce97-e2c5-4ab8-7ba5-7654dd08d52b"
- apiGroups: ["authentication.k8s.io"]
 resources: ["uids"]
 verbs: ["impersonate"]
 resourceNames: ["06f6ce97-e2c5-4ab8-7ba5-7654dd08d52b"]
```

#### Note:

Impersonating a user or group allows you to perform any action as if you were that user or group; for that reason, impersonation is not namespace scoped. If you want to allow impersonation using Kubernetes RBAC, this requires using a ClusterRole and a ClusterRoleBinding, not a Role and RoleBinding.

## client-go credential plugins

FEATURE STATE: Kubernetes v1.22 [stable]

k8s.io/client-go and tools using it such as kubectl and kubelet are able to execute an external command to receive user credentials.

This feature is intended for client side integrations with authentication protocols not natively supported by k8s.io/client-go (LDAP, Kerberos, OAuth2, SAML, etc.). The plugin implements the protocol specific logic, then returns opaque credentials to use. Almost all credential plugin use cases require a server side component with support for the [webhook token authenticator](#) to interpret the credential format produced by the client plugin.

#### Note:

Earlier versions of kubectl included built-in support for authenticating to AKS and GKE, but this is no longer present.

### Example use case

In a hypothetical use case, an organization would run an external service that exchanges LDAP credentials for user specific, signed tokens. The service would also be capable of responding to [webhook token authenticator](#) requests to validate the tokens. Users would be required to install a credential plugin on their workstation.

To authenticate against the API:

- The user issues a kubectl command.
- Credential plugin prompts the user for LDAP credentials, exchanges credentials with external service for a token.
- Credential plugin returns token to client-go, which uses it as a bearer token against the API server.
- API server uses the [webhook token authenticator](#) to submit a TokenReview to the external service.
- External service verifies the signature on the token and returns the user's username and groups.

## Configuration

Credential plugins are configured through [kubectl config files](#) as part of the user fields.

- [client.authentication.k8s.io/v1](#)
- [client.authentication.k8s.io/v1beta1](#)

```
apiVersion: v1
kind: Config
users:
- name: my-user
 user:
 exec:
 # Command to execute. Required.
 command: "example-client-go-exec-plugin"

 # API version to use when decoding the ExecCredentials resource. Required.
 #
 # The API version returned by the plugin MUST match the version listed here.
 #
 # To integrate with tools that support multiple versions (such as client.authentication.k8s.io/
v1beta1),

set an environment variable, pass an argument to the tool that indicates which version the
exec plugin expects,
or read the version from the ExecCredential object in the KUBERNETES_EXEC_INFO
environment variable.
 apiVersion: "client.authentication.k8s.io/v1"

 # Environment variables to set when executing the plugin. Optional.
 env:
 - name: "FOO"
 value: "bar"

 # Arguments to pass when executing the plugin. Optional.
 args:
 - "arg1"
 - "arg2"

 # Text shown to the user when the executable doesn't seem to be present. Optional.
 installHint: |
 example-client-go-exec-plugin is required to authenticate
 to the current cluster. It can be installed:

 On macOS: brew install example-client-go-exec-plugin

 On Ubuntu: apt-get install example-client-go-exec-plugin

 On Fedora: dnf install example-client-go-exec-plugin

 ...

 # Whether or not to provide cluster information, which could potentially contain
```

```

very large CA data, to this exec plugin as a part of the KUBERNETES_EXEC_INFO
environment variable.
provideClusterInfo: true

The contract between the exec plugin and the standard input I/O stream. If the
contract cannot be satisfied, this plugin will not be run and an error will be
returned. Valid values are "Never" (this exec plugin never uses standard input),
"IfAvailable" (this exec plugin wants to use standard input if it is available),
or "Always" (this exec plugin requires standard input to function). Required.
interactiveMode: Never

clusters:
- name: my-cluster
 cluster:
 server: "https://172.17.4.100:6443"
 certificate-authority: "/etc/kubernetes/ca.pem"
 extensions:
 - name: client.authentication.k8s.io/exec # reserved extension name for per cluster exec
 config
 extension:
 arbitrary: config
 this: can be provided via the KUBERNETES_EXEC_INFO environment variable upon
 setting provideClusterInfo
 you: ["can", "put", "anything", "here"]

Text shown to the user when the executable doesn't seem to be present. Optional.
installHint: |
 example-client-go-exec-plugin is required to authenticate
 to the current cluster. It can be installed:

 On macOS: brew install example-client-go-exec-plugin

 On Ubuntu: apt-get install example-client-go-exec-plugin

 On Fedora: dnf install example-client-go-exec-plugin

 ...

Whether or not to provide cluster information, which could potentially contain
very large CA data, to this exec plugin as a part of the KUBERNETES_EXEC_INFO
environment variable.
provideClusterInfo: true

The contract between the exec plugin and the standard input I/O stream. If the
contract cannot be satisfied, this plugin will not be run and an error will be
returned. Valid values are "Never" (this exec plugin never uses standard input),
"IfAvailable" (this exec plugin wants to use standard input if it is available),
or "Always" (this exec plugin requires standard input to function). Optional.
Defaults to "IfAvailable".
interactiveMode: Never

clusters:
- name: my-cluster
 cluster:
 server: "https://172.17.4.100:6443"
 certificate-authority: "/etc/kubernetes/ca.pem"
 extensions:
 - name: client.authentication.k8s.io/exec # reserved extension name for per cluster exec
 config
 extension:
 arbitrary: config
 this: can be provided via the KUBERNETES_EXEC_INFO environment variable upon
 setting provideClusterInfo
 you: ["can", "put", "anything", "here"]
 contexts:
 - name: my-cluster
 context:
 cluster: my-cluster
 user: my-user
 current-context: my-cluster

```

Relative command paths are interpreted as relative to the directory of the config file. If KUBECONFIG is set to /home/jane/kubeconfig and the exec command is ./bin/example-client-go-exec-plugin, the binary /home/jane/bin/example-client-go-exec-plugin is executed.

```
- name: my-user
 user:
 exec:
 # Path relative to the directory of the kubeconfig
 command: "./bin/example-client-go-exec-plugin"
 apiVersion: "client.authentication.k8s.io/v1"
 interactiveMode: Never
```

## Input and output formats

The executed command prints an ExecCredential object to stdout. k8s.io/client-go authenticates against the Kubernetes API using the returned credentials in the status. The executed command is passed an ExecCredential object as input via the KUBERNETES\_EXEC\_INFO environment variable. This input contains helpful information like the expected API version of the returned ExecCredential object and whether or not the plugin can use stdin to interact with the user.

When run from an interactive session (i.e., a terminal), stdin can be exposed directly to the plugin. Plugins should use the spec.interactive field of the input ExecCredential object from the KUBERNETES\_EXEC\_INFO environment variable in order to determine if stdin has been provided. A plugin's stdin requirements (i.e., whether stdin is optional, strictly required, or never used in order for the plugin to run successfully) is declared via the user.exec.interactiveMode field in the [kubeconfig](#) (see table below for valid values). The user.exec.interactiveMode field is optional in client.authentication.k8s.io/v1beta1 and required in client.authentication.k8s.io/v1.

interactiveMode values

| interactiveMode Value | Meaning                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Never                 | This exec plugin never needs to use standard input, and therefore the exec plugin will be run regardless of whether standard input is available for user input.                                                                                                                                                              |
| IfAvailable           | This exec plugin would like to use standard input if it is available, but can still operate if standard input is not available. Therefore, the exec plugin will be run regardless of whether stdin is available for user input. If standard input is available for user input, then it will be provided to this exec plugin. |
| Always                | This exec plugin requires standard input in order to run, and therefore the exec plugin will only be run if standard input is available for user input. If standard input is not available for user input, then the exec plugin will not be run and an error will be returned by the exec plugin runner.                     |

To use bearer token credentials, the plugin returns a token in the status of the [ExecCredential](#)

- [client.authentication.k8s.io/v1](#)
- [client.authentication.k8s.io/v1beta1](#)

```
{
 "apiVersion": "client.authentication.k8s.io/v1",
 "kind": "ExecCredential",
```

```

"status": {
 "token": "my-bearer-token"
}
}

```

```

{
 "apiVersion": "client.authentication.k8s.io/v1beta1",
 "kind": "ExecCredential",
 "status": {
 "token": "my-bearer-token"
 }
}

```

Alternatively, a PEM-encoded client certificate and key can be returned to use TLS client auth. If the plugin returns a different certificate and key on a subsequent call, k8s.io/client-go will close existing connections with the server to force a new TLS handshake.

If specified, clientKeyData and clientCertificateData must both be present.

clientCertificateData may contain additional intermediate certificates to send to the server.

- [client.authentication.k8s.io/v1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1-clientauthentication-k8s-io)
- [client.authentication.k8s.io/v1beta1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1beta1-clientauthentication-k8s-io)

```

{
 "apiVersion": "client.authentication.k8s.io/v1",
 "kind": "ExecCredential",
 "status": {
 "clientCertificateData": "-----BEGIN CERTIFICATE-----\n...\n-----END CERTIFICATE-----",
 "clientKeyData": "-----BEGIN RSA PRIVATE KEY-----\n...\n-----END RSA PRIVATE KEY-----"
 }
}

```

```

{
 "apiVersion": "client.authentication.k8s.io/v1beta1",
 "kind": "ExecCredential",
 "status": {
 "clientCertificateData": "-----BEGIN CERTIFICATE-----\n...\n-----END CERTIFICATE-----",
 "clientKeyData": "-----BEGIN RSA PRIVATE KEY-----\n...\n-----END RSA PRIVATE KEY-----"
 }
}

```

Optionally, the response can include the expiry of the credential formatted as a [RFC 3339](https://tools.ietf.org/html/rfc3339) timestamp.

Presence or absence of an expiry has the following impact:

- If an expiry is included, the bearer token and TLS credentials are cached until the expiry time is reached, or if the server responds with a 401 HTTP status code, or when the process exits.
  - If an expiry is omitted, the bearer token and TLS credentials are cached until the server responds with a 401 HTTP status code or until the process exits.
- [client.authentication.k8s.io/v1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1-clientauthentication-k8s-io)

- [client.authentication.k8s.io/v1beta1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1-client.authentication.k8s.io)

```
{
 "apiVersion": "client.authentication.k8s.io/v1",
 "kind": "ExecCredential",
 "status": {
 "token": "my-bearer-token",
 "expirationTimestamp": "2018-03-05T17:30:20-08:00"
 }
}
```

```
{
 "apiVersion": "client.authentication.k8s.io/v1beta1",
 "kind": "ExecCredential",
 "status": {
 "token": "my-bearer-token",
 "expirationTimestamp": "2018-03-05T17:30:20-08:00"
 }
}
```

To enable the exec plugin to obtain cluster-specific information, set `provideClusterInfo` on the `user.exec` field in the [kubeconfig](#). The plugin will then be supplied this cluster-specific information in the `KUBERNETES_EXEC_INFO` environment variable. Information from this environment variable can be used to perform cluster-specific credential acquisition logic. The following `ExecCredential` manifest describes a cluster information sample.

- [client.authentication.k8s.io/v1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1-client.authentication.k8s.io)
- [client.authentication.k8s.io/v1beta1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#execcredential-v1-client.authentication.k8s.io)

```
{
 "apiVersion": "client.authentication.k8s.io/v1",
 "kind": "ExecCredential",
 "spec": {
 "cluster": {
 "server": "https://172.17.4.100:6443",
 "certificate-authority-data": "LS0t...",
 "config": {
 "arbitrary": "config",
 "this": "can be provided via the KUBERNETES_EXEC_INFO environment variable upon setting provideClusterInfo",
 "you": ["can", "put", "anything", "here"]
 }
 },
 "interactive": true
 }
}
```

```
{
 "apiVersion": "client.authentication.k8s.io/v1beta1",
 "kind": "ExecCredential",
 "spec": {
 "cluster": {
 "server": "https://172.17.4.100:6443",
 "certificate-authority-data": "LS0t...",

```

```

 "config": {
 "arbitrary": "config",
 "this": "can be provided via the KUBERNETES_EXEC_INFO environment variable upon
setting provideClusterInfo",
 "you": ["can", "put", "anything", "here"]
 }
 },
 "interactive": true
}
}

```

## API access to authentication information for a client

FEATURE STATE: Kubernetes v1.28 [stable]

If your cluster has the API enabled, you can use the `SelfSubjectReview` API to find out how your Kubernetes cluster maps your authentication information to identify you as a client. This works whether you are authenticating as a user (typically representing a real person) or as a `ServiceAccount`.

`SelfSubjectReview` objects do not have any configurable fields. On receiving a request, the Kubernetes API server fills the status with the user attributes and returns it to the user.

Request example (the body would be a `SelfSubjectReview`):

POST `/apis/authentication.k8s.io/v1/selfsubjectreviews`

```

{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "SelfSubjectReview"
}

```

Response example:

```

{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "SelfSubjectReview",
 "status": {
 "userInfo": {
 "name": "jane.doe",
 "uid": "b6c7cfd4-f166-11ec-8ea0-0242ac120002",
 "groups": [
 "viewers",
 "editors",
 "system:authenticated"
],
 "extra": {
 "provider_id": ["token.company.example"]
 }
 }
 }
}

```

For convenience, the `kubectl auth whoami` command is present. Executing this command will produce the following output (yet different user attributes will be shown):

- Simple output example

| ATTRIBUTE | VALUE                  |
|-----------|------------------------|
| Username  | jane.doe               |
| Groups    | [system:authenticated] |

- Complex example including extra attributes

| ATTRIBUTE       | VALUE                                    |
|-----------------|------------------------------------------|
| Username        | jane.doe                                 |
| UID             | b79dbf30-0c6a-11ed-861d-0242ac120002     |
| Groups          | [students teachers system:authenticated] |
| Extra: skills   | [reading learning]                       |
| Extra: subjects | [math sports]                            |

By providing the output flag, it is also possible to print the JSON or YAML representation of the result:

- [JSON](#)
- [YAML](#)

```
{
 "apiVersion": "authentication.k8s.io/v1",
 "kind": "SelfSubjectReview",
 "status": {
 "userInfo": {
 "username": "jane.doe",
 "uid": "b79dbf30-0c6a-11ed-861d-0242ac120002",
 "groups": [
 "students",
 "teachers",
 "system:authenticated"
],
 "extra": {
 "skills": [
 "reading",
 "learning"
],
 "subjects": [
 "math",
 "sports"
]
 }
 }
 }
}
```

```
apiVersion: authentication.k8s.io/v1
kind: SelfSubjectReview
status:
 userInfo:
```

```
username: jane.doe
uid: b79dbf30-0c6a-11ed-861d-0242ac120002
groups:
- students
- teachers
- system:authenticated
extra:
skills:
- reading
- learning
subjects:
- math
- sports
```

This feature is extremely useful when a complicated authentication flow is used in a Kubernetes cluster, for example, if you use [webhook token authentication](#) or [authenticating proxy](#).

#### Note:

The Kubernetes API server fills the `userInfo` after all authentication mechanisms are applied, including [impersonation](#). If you, or an authentication proxy, make a `SelfSubjectReview` using impersonation, you see the user details and properties for the user that was impersonated.

By default, all authenticated users can create `SelfSubjectReview` objects when the `APISelfSubjectReview` feature is enabled. It is allowed by the `system:basic-user` cluster role.

#### Note:

You can only make `SelfSubjectReview` requests if:

- the `APISelfSubjectReview` [feature gate](#) is enabled for your cluster (not needed for Kubernetes 1.30, but older Kubernetes versions might not offer this feature gate, or might default it to be off)
- (if you are running a version of Kubernetes older than v1.28) the API server for your cluster has the `authentication.k8s.io/v1alpha1` or `authentication.k8s.io/v1beta1` [API group](#) enabled.

## What's next

- Read the [client authentication reference \(v1beta1\)](#)
- Read the [client authentication reference \(v1\)](#)

# Authenticating with Bootstrap Tokens

FEATURE STATE: Kubernetes v1.18 [stable]

Bootstrap tokens are a simple bearer token that is meant to be used when creating new clusters or joining new nodes to an existing cluster. It was built to support [kubeadm](#), but can be used in other contexts for users that wish to start clusters without `kubeadm`. It is also built to work, via RBAC policy, with the [Kubelet TLS Bootstrapping](#) system.

# Bootstrap Tokens Overview

Bootstrap Tokens are defined with a specific type (`bootstrap.kubernetes.io/token`) of secrets that lives in the `kube-system` namespace. These Secrets are then read by the Bootstrap Authenticator in the API Server. Expired tokens are removed with the TokenCleaner controller in the Controller Manager. The tokens are also used to create a signature for a specific ConfigMap used in a "discovery" process through a BootstrapSigner controller.

## Token Format

Bootstrap Tokens take the form of `abcdef.0123456789abcdef`. More formally, they must match the regular expression `[a-z0-9]{6}\.[a-z0-9]{16}`.

The first part of the token is the "Token ID" and is considered public information. It is used when referring to a token without leaking the secret part used for authentication. The second part is the "Token Secret" and should only be shared with trusted parties.

## Enabling Bootstrap Token Authentication

The Bootstrap Token authenticator can be enabled using the following flag on the API server:

```
--enable-bootstrap-token-auth
```

When enabled, bootstrapping tokens can be used as bearer token credentials to authenticate requests against the API server.

```
Authorization: Bearer 07401b.f395accd246ae52d
```

Tokens authenticate as the username `system:bootstrap:<token id>` and are members of the group `system:bootstrappers`. Additional groups may be specified in the token's Secret.

Expired tokens can be deleted automatically by enabling the `tokencleaner` controller on the controller manager.

```
--controllers=*,tokencleaner
```

## Bootstrap Token Secret Format

Each valid token is backed by a secret in the `kube-system` namespace. You can find the full design doc [here](#).

Here is what the secret looks like.

```
apiVersion: v1
kind: Secret
metadata:
 # Name MUST be of form "bootstrap-token-<token id>"
 name: bootstrap-token-07401b
 namespace: kube-system
Type MUST be 'bootstrap.kubernetes.io/token'
```

```
type: bootstrap.kubernetes.io/token
stringData:
 # Human readable description. Optional.
 description: "The default bootstrap token generated by 'kubeadm init'."

 # Token ID and secret. Required.
 token-id: 07401b
 token-secret: f395accd246ae52d

 # Expiration. Optional.
 expiration: 2017-03-10T03:22:11Z

 # Allowed usages.
 usage-bootstrap-authentication: "true"
 usage-bootstrap-signing: "true"

 # Extra groups to authenticate the token as. Must start with "system:bootstrappers:"
 auth-extra-groups: system:bootstrappers:worker,system:bootstrappers:ingress
```

The type of the secret must be `bootstrap.kubernetes.io/token` and the name must be `bootstrap-token-<token id>`. It must also exist in the `kube-system` namespace.

The `usage-bootstrap-*` members indicate what this secret is intended to be used for. A value must be set to `true` to be enabled.

- `usage-bootstrap-authentication` indicates that the token can be used to authenticate to the API server as a bearer token.
- `usage-bootstrap-signing` indicates that the token may be used to sign the cluster-info ConfigMap as described below.

The `expiration` field controls the expiry of the token. Expired tokens are rejected when used for authentication and ignored during ConfigMap signing. The expiry value is encoded as an absolute UTC time using RFC3339. Enable the `tokencleaner` controller to automatically delete expired tokens.

## Token Management with kubeadm

You can use the `kubeadm` tool to manage tokens on a running cluster. See the [kubeadm token docs](#) for details.

## ConfigMap Signing

In addition to authentication, the tokens can be used to sign a ConfigMap. This is used early in a cluster bootstrap process before the client trusts the API server. The signed ConfigMap can be authenticated by the shared token.

Enable ConfigMap signing by enabling the `bootstrapsigner` controller on the Controller Manager.

```
--controllers=*,bootstrapsigner
```

The ConfigMap that is signed is cluster-info in the kube-public namespace. The typical flow is that a client reads this ConfigMap while unauthenticated and ignoring TLS errors. It then validates the payload of the ConfigMap by looking at a signature embedded in the ConfigMap.

The ConfigMap may look like this:

```
apiVersion: v1
kind: ConfigMap
metadata:
 name: cluster-info
 namespace: kube-public
data:
 jws-kubeconfig-07401b: eyJhbGciOiJIUzI1NiIsImtpZCI6IjA3NDAxYiJ9..tYefbo6zDNo40MQE07aZcQX2m3EB2rO3NuXtxVMYm9U
 kubeconfig: |
 apiVersion: v1
 clusters:
 - cluster:
 certificate-authority-data: <really long certificate data>
 server: https://10.138.0.2:6443
 name: ""
 contexts: []
 current-context: ""
 kind: Config
 preferences: {}
 users: []
```

The kubeconfig member of the ConfigMap is a config file with only the cluster information filled out. The key thing being communicated here is the certificate-authority-data. This may be expanded in the future.

The signature is a JWS signature using the "detached" mode. To validate the signature, the user should encode the kubeconfig payload according to JWS rules (base64 encoded while discarding any trailing =). That encoded payload is then used to form a whole JWS by inserting it between the 2 dots. You can verify the JWS using the HS256 scheme (HMAC-SHA256) with the full token (e.g. 07401b.f395accd246ae52d) as the shared secret. Users *must* verify that HS256 is used.

### Warning:

Any party with a bootstrapping token can create a valid signature for that token. When using ConfigMap signing it's discouraged to share the same token with many clients, since a compromised client can potentially man-in-the middle another client relying on the signature to bootstrap TLS trust.

Consult the [kubeadm implementation details](#) section for more information.

## Authorization

Details of Kubernetes authorization mechanisms and supported authorization modes.

Kubernetes authorization takes place following [authentication](#). Usually, a client making a request must be authenticated (logged in) before its request can be allowed; however, Kubernetes also allows anonymous requests in some circumstances.

For an overview of how authorization fits into the wider context of API access control, read [Controlling Access to the Kubernetes API](#).

## Authorization verdicts

Kubernetes authorization of API requests takes place within the API server. The API server evaluates all of the request attributes against all policies, potentially also consulting external services, and then allows or denies the request.

All parts of an API request must be allowed by some authorization mechanism in order to proceed. In other words: access is denied by default.

### Note:

Access controls and policies that depend on specific fields of specific kinds of objects are handled by [admission controllers](#).

Kubernetes admission control happens after authorization has completed (and, therefore, only when the authorization decision was to allow the request).

When multiple [authorization modules](#) are configured, each is checked in sequence. If any authorizer *approves* or *denies* a request, that decision is immediately returned and no other authorizer is consulted. If all modules have *no opinion* on the request, then the request is denied. An overall deny verdict means that the API server rejects the request and responds with an HTTP 403 (Forbidden) status.

## Request attributes used in authorization

Kubernetes reviews only the following API request attributes:

- **user** - The user string provided during authentication.
- **group** - The list of group names to which the authenticated user belongs.
- **extra** - A map of arbitrary string keys to string values, provided by the authentication layer.
- **API** - Indicates whether the request is for an API resource.
- **Request path** - Path to miscellaneous non-resource endpoints like /api or /healthz.
- **API request verb** - API verbs like get, list, create, update, patch, watch, delete, and deletecollection are used for resource requests. To determine the request verb for a resource API endpoint, see [request verbs and authorization](#).
- **HTTP request verb** - Lowercased HTTP methods like get, post, put, and delete are used for non-resource requests.
- **Resource** - The ID or name of the resource that is being accessed (for resource requests only) -- For resource requests using get, update, patch, and delete verbs, you must provide the resource name.
- **Subresource** - The subresource that is being accessed (for resource requests only).
- **Namespace** - The namespace of the object that is being accessed (for namespaced resource requests only).

- **API group** - The [API Group](#) being accessed (for resource requests only). An empty string designates the *core* [API group](#).

## Request verbs and authorization

### Non-resource requests

Requests to endpoints other than `/api/v1/...` or `/apis/<group>/<version>/...` are considered *non-resource requests*, and use the lower-cased HTTP method of the request as the verb. For example, making a GET request using HTTP to endpoints such as `/api` or `/healthz` would use **get** as the verb.

### Resource requests

To determine the request verb for a resource API endpoint, Kubernetes maps the HTTP verb used and considers whether or not the request acts on an individual resource or on a collection of resources:

| HTTP verb | request verb                                                                                                                                                                       |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POST      | <b>create</b>                                                                                                                                                                      |
| GET, HEAD | <b>get</b> (for individual resources), <b>list</b> (for collections, including full object content), <b>watch</b> (for watching an individual resource or collection of resources) |
| PUT       | <b>update</b>                                                                                                                                                                      |
| PATCH     | <b>patch</b>                                                                                                                                                                       |
| DELETE    | <b>delete</b> (for individual resources), <b>deletecollection</b> (for collections)                                                                                                |

### Caution:

+The **get**, **list** and **watch** verbs can all return the full details of a resource. In terms of access to the returned data they are equivalent. For example, **list** on secrets will reveal the **data** attributes of any returned resources.

Kubernetes sometimes checks authorization for additional permissions using specialized verbs. For example:

- Special cases of [authentication](#)
  - **impersonate** verb on users, groups, and serviceaccounts in the core API group, and the userextras in the authentication.k8s.io API group.
- [Authorization of CertificateSigningRequests](#)
  - **approve** verb for CertificateSigningRequests, and **update** for revisions to existing approvals
- [RBAC](#)
  - **bind** and **escalate** verbs on roles and clusterroles resources in the rbac.authorization.k8s.io API group.

# Authorization context

Kubernetes expects attributes that are common to REST API requests. This means that Kubernetes authorization works with existing organization-wide or cloud-provider-wide access control systems which may handle other APIs besides the Kubernetes API.

## Authorization modes

The Kubernetes API server may authorize a request using one of several authorization modes:

### AlwaysAllow

This mode allows all requests, which brings [security risks](#). Use this authorization mode only if you do not require authorization for your API requests (for example, for testing).

### AlwaysDeny

This mode blocks all requests. Use this authorization mode only for testing.

### ABAC ([attribute-based access control](#))

Kubernetes ABAC mode defines an access control paradigm whereby access rights are granted to users through the use of policies which combine attributes together.

The policies can use any type of attributes (user attributes, resource attributes, object, environment attributes, etc).

### RBAC ([role-based access control](#))

Kubernetes RBAC is a method of regulating access to computer or network resources based on the roles of individual users within an enterprise. In this context, access is the ability of an individual user to perform a specific task, such as view, create, or modify a file.

In this mode, Kubernetes uses the `rbac.authorization.k8s.io` API group to drive authorization decisions, allowing you to dynamically configure permission policies through the Kubernetes API.

### Node

A special-purpose authorization mode that grants permissions to kubelets based on the pods they are scheduled to run. To learn more about the Node authorization mode, see [Node Authorization](#).

### Webhook

Kubernetes [webhook mode](#) for authorization makes a synchronous HTTP callout, blocking the request until the remote HTTP service responds to the query. You can write your own software to handle the callout, or use solutions from the ecosystem.

## Warning:

Enabling the AlwaysAllow mode bypasses authorization; do not use this on a cluster where you do not trust **all** potential API clients, including the workloads that you run.

Authorization mechanisms typically return either a *deny* or *no opinion* result; see [authorization verdicts](#) for more on this. Activating the AlwaysAllow means that if all other authorizers return “no opinion”, the request is allowed. For example, `--authorization-mode=AlwaysAllow,RBAC` has the same effect as `--authorization-mode=AlwaysAllow` because Kubernetes RBAC does not provide negative (deny) access rules.

You should not use the AlwaysAllow mode on a Kubernetes cluster where the API server is reachable from the public internet.

## Authorization mode configuration

You can configure the Kubernetes API server's authorizer chain using either [command line arguments](#) only or, as a beta feature, using a [configuration file](#).

You have to pick one of the two configuration approaches; setting both `--authorization-config` path and configuring an authorization webhook using the `--authorization-mode` and `--authorization-webhook-*` command line arguments is not allowed. If you try this, the API server reports an error message during startup, then exits immediately.

## Command line authorization mode configuration

FEATURE STATE: Kubernetes v1.8 [stable]

You can use the following modes:

- `--authorization-mode=ABAC` (Attribute-based access control mode)
- `--authorization-mode=RBAC` (Role-based access control mode)
- `--authorization-mode=Node` (Node authorizer)
- `--authorization-mode=Webhook` (Webhook authorization mode)
- `--authorization-mode=AlwaysAllow` (always allows requests; carries [security risks](#))
- `--authorization-mode=AlwaysDeny` (always denies requests)

You can choose more than one authorization mode; for example: `--authorization-mode=Node,Webhook`

Kubernetes checks authorization modules based on the order that you specify them on the API server's command line, so an earlier module has higher priority to allow or deny a request.

You cannot combine the `--authorization-mode` command line argument with the `--authorization-config` command line argument used for [configuring authorization using a local file](#).

For more information on command line arguments to the API server, read the [kube-apiserver reference](#).

## Configuring the API Server using an authorization config file

FEATURE STATE: Kubernetes v1.30 [beta]

As a beta feature, Kubernetes lets you configure authorization chains that can include multiple webhooks. The authorization items in that chain can have well-defined parameters that validate requests in a particular order, offering you fine-grained control, such as explicit Deny on failures.

The configuration file approach even allows you to specify [CEL](#) rules to pre-filter requests before they are dispatched to webhooks, helping you to prevent unnecessary invocations. The

API server also automatically reloads the authorizer chain when the configuration file is modified.

You specify the path to the authorization configuration using the `--authorization-config` command line argument.

If you want to use command line arguments instead of a configuration file, that's also a valid and supported approach. Some authorization capabilities (for example: multiple webhooks, webhook failure policy, and pre-filter rules) are only available if you use an authorization configuration file.

### Example configuration

```

#
DO NOT USE THE CONFIG AS IS. THIS IS AN EXAMPLE.
#
apiVersion: apiserver.config.k8s.io/v1beta1
kind: AuthorizationConfiguration
authorizers:
- type: Webhook
 # Name used to describe the authorizer
 # This is explicitly used in monitoring machinery for metrics
 # Note:
 # - Validation for this field is similar to how K8s labels are validated today.
 # Required, with no default
 name: webhook
 webhook:
 # The duration to cache 'authorized' responses from the webhook
 # authorizer.
 # Same as setting `--authorization-webhook-cache-authorized-ttl` flag
 # Default: 5m0s
 authorizedTTL: 30s
 # The duration to cache 'unauthorized' responses from the webhook
 # authorizer.
 # Same as setting `--authorization-webhook-cache-unauthorized-ttl` flag
 # Default: 30s
 unauthorizedTTL: 30s
 # Timeout for the webhook request
 # Maximum allowed is 30s.
 # Required, with no default.
 timeout: 3s
 # The API version of the authorization.k8s.io SubjectAccessReview to
 # send to and expect from the webhook.
 # Same as setting `--authorization-webhook-version` flag
 # Required, with no default
 # Valid values: v1beta1, v1
 subjectAccessReviewVersion: v1
 # MatchConditionSubjectAccessReviewVersion specifies the SubjectAccessReview
 # version the CEL expressions are evaluated against
 # Valid values: v1
 # Required, no default value
 matchConditionSubjectAccessReviewVersion: v1
```

```

Controls the authorization decision when a webhook request fails to
complete or returns a malformed response or errors evaluating
matchConditions.
Valid values:
- NoOpinion: continue to subsequent authorizers to see if one of
them allows the request
- Deny: reject the request without consulting subsequent authorizers
Required, with no default.
failurePolicy: Deny
connectionInfo:
 # Controls how the webhook should communicate with the server.
 # Valid values:
 # - KubeConfig: use the file specified in kubeConfigFile to locate the
 # server.
 # - InClusterConfig: use the in-cluster configuration to call the
 # SubjectAccessReview API hosted by kube-apiserver. This mode is not
 # allowed for kube-apiserver.
 type: KubeConfig
 # Path to KubeConfigFile for connection info
 # Required, if connectionInfo.Type is KubeConfig
 kubeConfigFile: /kube-system-authz-webhook.yaml
 # matchConditions is a list of conditions that must be met for a request to be sent to this
 # webhook. An empty list of matchConditions matches all requests.
 # There are a maximum of 64 match conditions allowed.
 #
 # The exact matching logic is (in order):
 # 1. If at least one matchCondition evaluates to FALSE, then the webhook is skipped.
 # 2. If ALL matchConditions evaluate to TRUE, then the webhook is called.
 # 3. If at least one matchCondition evaluates to an error (but none are FALSE):
 # - If failurePolicy=Deny, then the webhook rejects the request
 # - If failurePolicy=NoOpinion, then the error is ignored and the webhook is skipped
matchConditions:
expression represents the expression which will be evaluated by CEL. Must evaluate to
bool.
CEL expressions have access to the contents of the SubjectAccessReview in v1 version.
If version specified by subjectAccessReviewVersion in the request variable is v1beta1,
the contents would be converted to the v1 version before evaluating the CEL expression.
#
Documentation on CEL: https://kubernetes.io/docs/reference/using-api/cel/
#
only send resource requests to the webhook
- expression: has(request.resourceAttributes)
only intercept requests to kube-system
- expression: request.resourceAttributes.namespace == 'kube-system'
don't intercept requests from kube-system service accounts
- expression: !('system:serviceaccounts:kube-system' in request.user.groups)
- type: Node
 name: node
- type: RBAC
 name: rbac
- type: Webhook
 name: in-cluster-authorizer
webhook:

```

```
authorizedTTL: 5m
unauthorizedTTL: 30s
timeout: 3s
subjectAccessReviewVersion: v1
failurePolicy: NoOpinion
connectionInfo:
 type: InClusterConfig
```

When configuring the authorizer chain using a configuration file, make sure all the control plane nodes have the same file contents. Take a note of the API server configuration when upgrading / downgrading your clusters. For example, if upgrading from Kubernetes 1.29 to Kubernetes 1.30, you would need to make sure the config file is in a format that Kubernetes 1.30 can understand, before you upgrade the cluster. If you downgrade to 1.29, you would need to set the configuration appropriately.

## Authorization configuration and reloads

Kubernetes reloads the authorization configuration file when the API server observes a change to the file, and also on a 60 second schedule if no change events were observed.

### Note:

You must ensure that all non-webhook authorizer types remain unchanged in the file on reload.

A reload **must not** add or remove Node or RBAC authorizers (they can be reordered, but cannot be added or removed).

## Privilege escalation via workload creation or edits

Users who can create/edit pods in a namespace, either directly or through an object that enables indirect [workload management](#), may be able to escalate their privileges in that namespace. The potential routes to privilege escalation include Kubernetes [API extensions](#) and their associated [controllers](#).

### Caution:

As a cluster administrator, use caution when granting access to create or edit workloads. Some details of how these can be misused are documented in [escalation paths](#).

## Escalation paths

There are different ways that an attacker or untrustworthy user could gain additional privilege within a namespace, if you allow them to run arbitrary Pods in that namespace:

- Mounting arbitrary Secrets in that namespace
  - Can be used to access confidential information meant for other workloads
  - Can be used to obtain a more privileged ServiceAccount's service account token
- Using arbitrary ServiceAccounts in that namespace
  - Can perform Kubernetes API actions as another workload (impersonation)
  - Can perform any privileged actions that ServiceAccount has

- Mounting or using ConfigMaps meant for other workloads in that namespace
  - Can be used to obtain information meant for other workloads, such as database host names.
- Mounting volumes meant for other workloads in that namespace
  - Can be used to obtain information meant for other workloads, and change it.

### Caution:

As a system administrator, you should be cautious when deploying CustomResourceDefinitions that let users make changes to the above areas. These may open privilege escalations paths. Consider the consequences of this kind of change when deciding on your authorization controls.

## Checking API access

kubectl provides the `auth can-i` subcommand for quickly querying the API authorization layer. The command uses the `SelfSubjectAccessReview` API to determine if the current user can perform a given action, and works regardless of the authorization mode used.

```
kubectl auth can-i create deployments --namespace dev
```

The output is similar to this:

```
yes
```

```
kubectl auth can-i create deployments --namespace prod
```

The output is similar to this:

```
no
```

Administrators can combine this with [user impersonation](#) to determine what action other users can perform.

```
kubectl auth can-i list secrets --namespace dev --as dave
```

The output is similar to this:

```
no
```

Similarly, to check whether a ServiceAccount named `dev-sa` in Namespace `dev` can list Pods in the Namespace `target`:

```
kubectl auth can-i list pods \
 --namespace target \
 --as system:serviceaccount:dev:dev-sa
```

The output is similar to this:

```
yes
```

`SelfSubjectAccessReview` is part of the `authorization.k8s.io` API group, which exposes the API server authorization to external services. Other resources in this group include:

### SubjectAccessReview

Access review for any user, not only the current one. Useful for delegating authorization decisions to the API server. For example, the kubelet and extension API servers use this to determine user access to their own APIs.

### LocalSubjectAccessReview

Like SubjectAccessReview but restricted to a specific namespace.

### SelfSubjectRulesReview

A review which returns the set of actions a user can perform within a namespace. Useful for users to quickly summarize their own access, or for UIs to hide/show actions.

These APIs can be queried by creating normal Kubernetes resources, where the response status field of the returned object is the result of the query. For example:

```
kubectl create -f - -o yaml << EOF
apiVersion: authorization.k8s.io/v1
kind: SelfSubjectAccessReview
spec:
 resourceAttributes:
 group: apps
 resource: deployments
 verb: create
 namespace: dev
EOF
```

The generated SelfSubjectAccessReview is similar to:

```
apiVersion: authorization.k8s.io/v1
kind: SelfSubjectAccessReview
metadata:
 creationTimestamp: null
spec:
 resourceAttributes:
 group: apps
 resource: deployments
 namespace: dev
 verb: create
status:
 allowed: true
 denied: false
```

## What's next

- To learn more about Authentication, see [Authentication](#).
- For an overview, read [Controlling Access to the Kubernetes API](#).
- To learn more about Admission Control, see [Using Admission Controllers](#).
- Read more about [Common Expression Language in Kubernetes](#).

## Using RBAC Authorization

Role-based access control (RBAC) is a method of regulating access to computer or network resources based on the roles of individual users within your organization.

RBAC authorization uses the `rbac.authorization.k8s.io` [API group](#) to drive authorization decisions, allowing you to dynamically configure policies through the Kubernetes API.

To enable RBAC, start the [API server](#) with the `--authorization-mode` flag set to a comma-separated list that includes RBAC; for example:

```
kube-apiserver --authorization-mode=Example,RBAC --other-options --more-options
```

## API objects

The RBAC API declares four kinds of Kubernetes object: *Role*, *ClusterRole*, *RoleBinding* and *ClusterRoleBinding*. You can describe or amend the RBAC [objects](#) using tools such as `kubectl`, just like any other Kubernetes object.

### Caution:

These objects, by design, impose access restrictions. If you are making changes to a cluster as you learn, see [privilege escalation prevention and bootstrapping](#) to understand how those restrictions can prevent you making some changes.

## Role and ClusterRole

An RBAC *Role* or *ClusterRole* contains rules that represent a set of permissions. Permissions are purely additive (there are no "deny" rules).

A Role always sets permissions within a particular [namespace](#); when you create a Role, you have to specify the namespace it belongs in.

ClusterRole, by contrast, is a non-namespaced resource. The resources have different names (Role and ClusterRole) because a Kubernetes object always has to be either namespaced or not namespaced; it can't be both.

ClusterRoles have several uses. You can use a ClusterRole to:

1. define permissions on namespaced resources and be granted access within individual namespace(s)
2. define permissions on namespaced resources and be granted access across all namespaces
3. define permissions on cluster-scoped resources

If you want to define a role within a namespace, use a Role; if you want to define a role cluster-wide, use a ClusterRole.

### Role example

Here's an example Role in the "default" namespace that can be used to grant read access to [pods](#):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
 namespace: default
 name: pod-reader
```

rules:

```
- apiGroups: [""] # "" indicates the core API group
resources: ["pods"]
verbs: ["get", "watch", "list"]
```

## ClusterRole example

A ClusterRole can be used to grant the same permissions as a Role. Because ClusterRoles are cluster-scoped, you can also use them to grant access to:

- cluster-scoped resources (like [nodes](#))
- non-resource endpoints (like `/healthz`)
- namespaced resources (like Pods), across all namespaces

For example: you can use a ClusterRole to allow a particular user to run `kubectl get pods --all-namespaces`

Here is an example of a ClusterRole that can be used to grant read access to [secrets](#) in any particular namespace, or across all namespaces (depending on how it is [bound](#)):

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 # "namespace" omitted since ClusterRoles are not namespaced
 name: secret-reader
rules:
- apiGroups: [""]
 #
 # at the HTTP level, the name of the resource for accessing Secret
 # objects is "secrets"
 resources: ["secrets"]
 verbs: ["get", "watch", "list"]
```

The name of a Role or a ClusterRole object must be a valid [path segment name](#).

## RoleBinding and ClusterRoleBinding

A role binding grants the permissions defined in a role to a user or set of users. It holds a list of *subjects* (users, groups, or service accounts), and a reference to the role being granted. A RoleBinding grants permissions within a specific namespace whereas a ClusterRoleBinding grants that access cluster-wide.

A RoleBinding may reference any Role in the same namespace. Alternatively, a RoleBinding can reference a ClusterRole and bind that ClusterRole to the namespace of the RoleBinding. If you want to bind a ClusterRole to all the namespaces in your cluster, you use a ClusterRoleBinding.

The name of a RoleBinding or ClusterRoleBinding object must be a valid [path segment name](#).

## RoleBinding examples

Here is an example of a RoleBinding that grants the "pod-reader" Role to the user "jane" within the "default" namespace. This allows "jane" to read pods in the "default" namespace.

```
apiVersion: rbac.authorization.k8s.io/v1
This role binding allows "jane" to read pods in the "default" namespace.
You need to already have a Role named "pod-reader" in that namespace.
kind: RoleBinding
metadata:
 name: read-pods
 namespace: default
subjects:
You can specify more than one "subject"
- kind: User
 name: jane # "name" is case sensitive
 apiGroup: rbac.authorization.k8s.io
roleRef:
"roleRef" specifies the binding to a Role / ClusterRole
kind: Role #this must be Role or ClusterRole
name: pod-reader # this must match the name of the Role or ClusterRole you wish to bind to
apiGroup: rbac.authorization.k8s.io
```

A RoleBinding can also reference a ClusterRole to grant the permissions defined in that ClusterRole to resources inside the RoleBinding's namespace. This kind of reference lets you define a set of common roles across your cluster, then reuse them within multiple namespaces.

For instance, even though the following RoleBinding refers to a ClusterRole, "dave" (the subject, case sensitive) will only be able to read Secrets in the "development" namespace, because the RoleBinding's namespace (in its metadata) is "development".

```
apiVersion: rbac.authorization.k8s.io/v1
This role binding allows "dave" to read secrets in the "development" namespace.
You need to already have a ClusterRole named "secret-reader".
kind: RoleBinding
metadata:
 name: read-secrets
 #
 # The namespace of the RoleBinding determines where the permissions are granted.
 # This only grants permissions within the "development" namespace.
 namespace: development
subjects:
- kind: User
 name: dave # Name is case sensitive
 apiGroup: rbac.authorization.k8s.io
roleRef:
 kind: ClusterRole
 name: secret-reader
 apiGroup: rbac.authorization.k8s.io
```

## ClusterRoleBinding example

To grant permissions across a whole cluster, you can use a ClusterRoleBinding. The following ClusterRoleBinding allows any user in the group "manager" to read secrets in any namespace.

```
apiVersion: rbac.authorization.k8s.io/v1
This cluster role binding allows anyone in the "manager" group to read secrets in any
namespace.
kind: ClusterRoleBinding
metadata:
 name: read-secrets-global
subjects:
- kind: Group
 name: manager # Name is case sensitive
 apiGroup: rbac.authorization.k8s.io
roleRef:
 kind: ClusterRole
 name: secret-reader
 apiGroup: rbac.authorization.k8s.io
```

After you create a binding, you cannot change the Role or ClusterRole that it refers to. If you try to change a binding's roleRef, you get a validation error. If you do want to change the roleRef for a binding, you need to remove the binding object and create a replacement.

There are two reasons for this restriction:

1. Making roleRef immutable allows granting someone update permission on an existing binding object, so that they can manage the list of subjects, without being able to change the role that is granted to those subjects.
2. A binding to a different role is a fundamentally different binding. Requiring a binding to be deleted/recreated in order to change the roleRef ensures the full list of subjects in the binding is intended to be granted the new role (as opposed to enabling or accidentally modifying only the roleRef without verifying all of the existing subjects should be given the new role's permissions).

The `kubectl auth reconcile` command-line utility creates or updates a manifest file containing RBAC objects, and handles deleting and recreating binding objects if required to change the role they refer to. See [command usage and examples](#) for more information.

## Referring to resources

In the Kubernetes API, most resources are represented and accessed using a string representation of their object name, such as pods for a Pod. RBAC refers to resources using exactly the same name that appears in the URL for the relevant API endpoint. Some Kubernetes APIs involve a *subresource*, such as the logs for a Pod. A request for a Pod's logs looks like:

```
GET /api/v1/namespaces/{namespace}/pods/{name}/log
```

In this case, pods is the namespaced resource for Pod resources, and log is a subresource of pods. To represent this in an RBAC role, use a slash (/) to delimit the resource and subresource. To allow a subject to read pods and also access the log subresource for each of those Pods, you write:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
 namespace: default
 name: pod-and-pod-logs-reader
rules:
- apiGroups: [""]
 resources: ["pods", "pods/log"]
 verbs: ["get", "list"]
```

You can also refer to resources by name for certain requests through the `resourceNames` list. When specified, requests can be restricted to individual instances of a resource. Here is an example that restricts its subject to only get or update a [ConfigMap](#) named my-configmap:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
 namespace: default
 name: configmap-updater
rules:
- apiGroups: [""]
 #
 # at the HTTP level, the name of the resource for accessing ConfigMap
 # objects is "configmaps"
 resources: ["configmaps"]
 resourceNames: ["my-configmap"]
 verbs: ["update", "get"]
```

#### **Note:**

You cannot restrict create or delete requests by their resource name. For create, this limitation is because the name of the new object may not be known at authorization time. If you restrict list or watch by `resourceName`, clients must include a `metadata.name` field selector in their list or watch request that matches the specified `resourceName` in order to be authorized. For example, `kubectl get configmaps --field-selector=metadata.name=my-configmap`

Rather than referring to individual resources, `apiGroups`, and verbs, you can use the wildcard `*` symbol to refer to all such objects. For nonResourceURLs, you can use the wildcard `*` as a suffix glob match. For `resourceNames`, an empty set means that everything is allowed. Here is an example that allows access to perform any current and future action on all current and future resources in the example.com API group. This is similar to the built-in cluster-admin role.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
 namespace: default
 name: example.com-superuser # DO NOT USE THIS ROLE, IT IS JUST AN EXAMPLE
rules:
- apiGroups: ["example.com"]
 resources: ["*"]
 verbs: ["*"]
```

### Caution:

Using wildcards in resource and verb entries could result in overly permissive access being granted to sensitive resources. For instance, if a new resource type is added, or a new subresource is added, or a new custom verb is checked, the wildcard entry automatically grants access, which may be undesirable. The [principle of least privilege](#) should be employed, using specific resources and verbs to ensure only the permissions required for the workload to function correctly are applied.

## Aggregated ClusterRoles

You can *aggregate* several ClusterRoles into one combined ClusterRole. A controller, running as part of the cluster control plane, watches for ClusterRole objects with an aggregationRule set. The aggregationRule defines a label [selector](#) that the controller uses to match other ClusterRole objects that should be combined into the rules field of this one.

### Caution:

The control plane overwrites any values that you manually specify in the rules field of an aggregate ClusterRole. If you want to change or add rules, do so in the ClusterRole objects that are selected by the aggregationRule.

Here is an example aggregated ClusterRole:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: monitoring
aggregationRule:
 clusterRoleSelectors:
 - matchLabels:
 rbac.example.com/aggregate-to-monitoring: "true"
rules: [] # The control plane automatically fills in the rules
```

If you create a new ClusterRole that matches the label selector of an existing aggregated ClusterRole, that change triggers adding the new rules into the aggregated ClusterRole. Here is an example that adds rules to the "monitoring" ClusterRole, by creating another ClusterRole labeled rbac.example.com/aggregate-to-monitoring: true.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: monitoring-endpoints
labels:
 rbac.example.com/aggregate-to-monitoring: "true"
When you create the "monitoring-endpoints" ClusterRole,
the rules below will be added to the "monitoring" ClusterRole.
rules:
- apiGroups: [""]
 resources: ["services", "endpointslices", "pods"]
 verbs: ["get", "list", "watch"]
```

The [default user-facing roles](#) use ClusterRole aggregation. This lets you, as a cluster administrator, include rules for custom resources, such as those served by [CustomResourceDefinitions](#) or aggregated API servers, to extend the default roles.

For example: the following ClusterRoles let the "admin" and "edit" default roles manage the custom resource named CronTab, whereas the "view" role can perform only read actions on CronTab resources. You can assume that CronTab objects are named "crontabs" in URLs as seen by the API server.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: aggregate-cron-tabs-edit
 labels:
 # Add these permissions to the "admin" and "edit" default roles.
 rbac.authorization.k8s.io/aggregate-to-admin: "true"
 rbac.authorization.k8s.io/aggregate-to-edit: "true"
rules:
- apiGroups: ["stable.example.com"]
 resources: ["crontabs"]
 verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]

kind: ClusterRole
apiVersion: rbac.authorization.k8s.io/v1
metadata:
 name: aggregate-cron-tabs-view
 labels:
 # Add these permissions to the "view" default role.
 rbac.authorization.k8s.io/aggregate-to-view: "true"
rules:
- apiGroups: ["stable.example.com"]
 resources: ["crontabs"]
 verbs: ["get", "list", "watch"]
```

## Role examples

The following examples are excerpts from Role or ClusterRole objects, showing only the rules section.

Allow reading "pods" resources in the core [API Group](#):

```
rules:
- apiGroups: [""]
 #
 # at the HTTP level, the name of the resource for accessing Pod
 # objects is "pods"
 resources: ["pods"]
 verbs: ["get", "list", "watch"]
```

Allow reading/writing Deployments (at the HTTP level: objects with "deployments" in the resource part of their URL) in the "apps" API groups:

rules:

```
- apiGroups: ["apps"]
#
at the HTTP level, the name of the resource for accessing Deployment
objects is "deployments"
resources: ["deployments"]
verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Allow reading Pods in the core API group, as well as reading or writing Job resources in the "batch" API group:

rules:

```
- apiGroups: [""]
#
at the HTTP level, the name of the resource for accessing Pod
objects is "pods"
resources: ["pods"]
verbs: ["get", "list", "watch"]
- apiGroups: ["batch"]
#
at the HTTP level, the name of the resource for accessing Job
objects is "jobs"
resources: ["jobs"]
verbs: ["get", "list", "watch", "create", "update", "patch", "delete"]
```

Allow reading a ConfigMap named "my-config" (must be bound with a RoleBinding to limit to a single ConfigMap in a single namespace):

rules:

```
- apiGroups: [""]
#
at the HTTP level, the name of the resource for accessing ConfigMap
objects is "configmaps"
resources: ["configmaps"]
resourceNames: ["my-config"]
verbs: ["get"]
```

Allow reading the resource "nodes" in the core group (because a Node is cluster-scoped, this must be in a ClusterRole bound with a ClusterRoleBinding to be effective):

rules:

```
- apiGroups: [""]
#
at the HTTP level, the name of the resource for accessing Node
objects is "nodes"
resources: ["nodes"]
verbs: ["get", "list", "watch"]
```

Allow GET and POST requests to the non-resource endpoint `/healthz` and all subpaths (must be in a ClusterRole bound with a ClusterRoleBinding to be effective):

rules:

```
- nonResourceURLs: ["/healthz", "/healthz/*"] # '*' in a nonResourceURL is a suffix glob match
verbs: ["get", "post"]
```

## Referring to subjects

A RoleBinding or ClusterRoleBinding binds a role to subjects. Subjects can be groups, users or [ServiceAccounts](#).

Kubernetes represents usernames as strings. These can be: plain names, such as "alice"; email-style names, like "bob@example.com"; or numeric user IDs represented as a string. It is up to you as a cluster administrator to configure the [authentication modules](#) so that authentication produces usernames in the format you want.

### Caution:

The prefix `system:` is reserved for Kubernetes system use, so you should ensure that you don't have users or groups with names that start with `system:` by accident. Other than this special prefix, the RBAC authorization system does not require any format for usernames.

In Kubernetes, Authenticator modules provide group information. Groups, like users, are represented as strings, and that string has no format requirements, other than that the prefix `system:` is reserved.

[ServiceAccounts](#) have names prefixed with `system:serviceaccount:`, and belong to groups that have names prefixed with `system:serviceaccounts:`.

### Note:

- `system:serviceaccount:` (singular) is the prefix for service account usernames.
- `system:serviceaccounts:` (plural) is the prefix for service account groups.

## RoleBinding examples

The following examples are RoleBinding excerpts that only show the subjects section.

For a user named `alice@example.com`:

```
subjects:
- kind: User
 name: "alice@example.com"
 apiGroup: rbac.authorization.k8s.io
```

For a group named `frontend-admins`:

```
subjects:
- kind: Group
 name: "frontend-admins"
 apiGroup: rbac.authorization.k8s.io
```

For the default service account in the "kube-system" namespace:

```
subjects:
- kind: ServiceAccount
 name: default
 namespace: kube-system
```

For all service accounts in the "qa" namespace:

```
subjects:
- kind: Group
 name: system:serviceaccounts:qa
 apiGroup: rbac.authorization.k8s.io
```

For all service accounts in any namespace:

```
subjects:
- kind: Group
 name: system:serviceaccounts
 apiGroup: rbac.authorization.k8s.io
```

For all authenticated users:

```
subjects:
- kind: Group
 name: system:authenticated
 apiGroup: rbac.authorization.k8s.io
```

For all unauthenticated users:

```
subjects:
- kind: Group
 name: system:unauthenticated
 apiGroup: rbac.authorization.k8s.io
```

For all users:

```
subjects:
- kind: Group
 name: system:authenticated
 apiGroup: rbac.authorization.k8s.io
- kind: Group
 name: system:unauthenticated
 apiGroup: rbac.authorization.k8s.io
```

## Default roles and role bindings

API servers create a set of default ClusterRole and ClusterRoleBinding objects. Many of these are system: prefixed, which indicates that the resource is directly managed by the cluster control plane. All of the default ClusterRoles and ClusterRoleBindings are labeled with `kubernetes.io/bootstrapping=rbac-defaults`.

### Caution:

Take care when modifying ClusterRoles and ClusterRoleBindings with names that have a `system:` prefix. Modifications to these resources can result in non-functional clusters.

## Auto-reconciliation

At each start-up, the API server updates default cluster roles with any missing permissions, and updates default cluster role bindings with any missing subjects. This allows the cluster to repair accidental modifications, and helps to keep roles and role bindings up-to-date as permissions and subjects change in new Kubernetes releases.

To opt out of this reconciliation, set the `rbac.authorization.kubernetes.io/autoupdate` annotation on a default cluster role or rolebinding to false. Be aware that missing default permissions and subjects can result in non-functional clusters.

Auto-reconciliation is enabled by default if the RBAC authorizer is active.

## API discovery roles

Default role bindings authorize unauthenticated and authenticated users to read API information that is deemed safe to be publicly accessible (including CustomResourceDefinitions). To disable anonymous unauthenticated access, add `--anonymous-auth=false` to the API server configuration.

To view the configuration of these roles via `kubectl` run:

```
kubectl get clusterroles system:discovery -o yaml
```

### Note:

If you edit that ClusterRole, your changes will be overwritten on API server restart via [auto-reconciliation](#). To avoid that overwriting, either do not manually edit the role, or disable auto-reconciliation.

Kubernetes RBAC API discovery roles

| Default ClusterRole              | Default ClusterRoleBinding                                           | Description                                                                                                                                                                                   |
|----------------------------------|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>system:basic-user</b>         | <b>system:authenticated</b> group                                    | Allows a user read-only access to basic information about themselves. Prior to v1.14, this role was also bound to <code>system:unauthenticated</code> by default.                             |
| <b>system:discovery</b>          | <b>system:authenticated</b> group                                    | Allows read-only access to API discovery endpoints needed to discover and negotiate an API level. Prior to v1.14, this role was also bound to <code>system:unauthenticated</code> by default. |
| <b>system:public-info-viewer</b> | <b>system:authenticated</b> and <b>system:unauthenticated</b> groups | Allows read-only access to non-sensitive information about the cluster. Introduced in Kubernetes v1.14.                                                                                       |

## User-facing roles

Some of the default ClusterRoles are not `system:` prefixed. These are intended to be user-facing roles. They include super-user roles (cluster-admin), roles intended to be granted cluster-wide using ClusterRoleBindings, and roles intended to be granted within particular namespaces using RoleBindings (admin, edit, view).

User-facing ClusterRoles use [ClusterRole aggregation](#) to allow admins to include rules for custom resources on these ClusterRoles. To add rules to the admin, edit, or view roles, create a ClusterRole with one or more of the following labels:

metadata:

labels:

rbac.authorization.k8s.io/aggregate-to-admin: "true"

rbac.authorization.k8s.io/aggregate-to-edit: "true"

rbac.authorization.k8s.io/aggregate-to-view: "true"

| Default ClusterRole  | Default ClusterRoleBinding  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cluster-admin</b> | <b>system:masters</b> group | Allows super-user access to perform any action on any resource. When used in a <b>ClusterRoleBinding</b> , it gives full control over every resource in the cluster and in all namespaces. When used in a <b>RoleBinding</b> , it gives full control over every resource in the role binding's namespace, including the namespace itself.                                                                                                                                                                                                                                                                     |
| <b>admin</b>         | None                        | <p>Allows admin access, intended to be granted within a namespace using a <b>RoleBinding</b>.</p> <p>If used in a <b>RoleBinding</b>, allows read/write access to most resources in a namespace, including the ability to create roles and role bindings within the namespace. This role does not allow write access to resource quota or to the namespace itself. This role also does not allow write access to EndpointSlices (or Endpoints) in clusters created using Kubernetes v1.22+. More information is available in the <a href="#">"Write Access for EndpointSlices and Endpoints" section</a>.</p> |
| <b>edit</b>          | None                        | <p>Allows read/write access to most objects in a namespace.</p> <p>This role does not allow viewing or modifying roles or role bindings. However, this role allows accessing Secrets and running Pods as any ServiceAccount in the namespace, so it can be used to gain the API access levels of any ServiceAccount in the namespace. This role also does not allow write access to EndpointSlices (or Endpoints) in clusters created using Kubernetes v1.22+. More information is available in the <a href="#">"Write Access for EndpointSlices and Endpoints" section</a>.</p>                              |
| <b>view</b>          | None                        | <p>Allows read-only access to see most objects in a namespace. It does not allow viewing roles or role bindings.</p> <p>This role does not allow viewing Secrets, since reading the contents of Secrets enables access to ServiceAccount credentials in the namespace, which would allow API access as any ServiceAccount in the namespace (a form of privilege escalation).</p>                                                                                                                                                                                                                              |

## Core component roles

| Default ClusterRole                         | Default ClusterRoleBinding                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>system:kube-scheduler</code>          | <code>system:kube-scheduler</code> user          | Allows access to the resources required by the <a href="#">scheduler</a> component.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>system:volume-scheduler</code>        | <code>system:kube-scheduler</code> user          | Allows access to the volume resources required by the kube-scheduler component.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>system:kube-controller-manager</code> | <code>system:kube-controller-manager</code> user | Allows access to the resources required by the <a href="#">controller manager</a> component. The permissions required by individual controllers are detailed in the <a href="#">controller roles</a> .                                                                                                                                                                                                                                                                                                                                       |
| <code>system:node</code>                    | None                                             | <p>Allows access to resources required by the kubelet, <b>including read access to all secrets, and write access to all pod status objects.</b></p> <p>You should use the <a href="#">Node authorizer</a> and <a href="#">NodeRestriction admission plugin</a> instead of the <code>system:node</code> role, and allow granting API access to kubelets based on the Pods scheduled to run on them.</p> <p>The <code>system:node</code> role only exists for compatibility with Kubernetes clusters upgraded from versions prior to v1.8.</p> |
| <code>system:node-proxier</code>            | <code>system:kube-proxy</code> user              | Allows access to the resources required by the <a href="#">kube-proxy</a> component.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Other component roles

| Default ClusterRole                       | Default ClusterRoleBinding                                                      | Description                                                                                                                                         |
|-------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>system:auth-delegator</code>        | None                                                                            | Allows delegated authentication and authorization checks. This is commonly used by add-on API servers for unified authentication and authorization. |
| <code>system:heapster</code>              | None                                                                            | Role for the <a href="#">Heapster</a> component (deprecated).                                                                                       |
| <code>system:kube-aggregator</code>       | None                                                                            | Role for the <a href="#">kube-aggregator</a> component.                                                                                             |
| <code>system:kube-dns</code>              | <code>kube-dns</code> service account in the <code>kube-system</code> namespace | Role for the <a href="#">kube-dns</a> component.                                                                                                    |
| <code>system:kubelet-api-admin</code>     | None                                                                            | Allows full access to the kubelet API.                                                                                                              |
| <code>system:node-bootstrapper</code>     | None                                                                            | Allows access to the resources required to perform <a href="#">kubelet TLS bootstrapping</a> .                                                      |
| <code>system:node-problem-detector</code> | None                                                                            | Role for the <a href="#">node-problem-detector</a> component.                                                                                       |

| Default ClusterRole                         | Default ClusterRoleBinding     | Description                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>system:persistent-volume-provisioner</b> | None                           | Allows access to the resources required by most <a href="#">dynamic volume provisioners</a> .                                                                                                                                                                                                                                                             |
| <b>system:monitoring</b>                    | <b>system:monitoring</b> group | Allows read access to control-plane monitoring endpoints (i.e. <a href="#">kube-apiserver</a> liveness and readiness endpoints (/healthz, /livez, /readyz), the individual health-check endpoints (/healthz/*, /livez/*, /readyz/*), and /metrics). Note that individual health check endpoints and the metric endpoint may expose sensitive information. |

## Roles for built-in controllers

The Kubernetes [controller manager](#) runs [controllers](#) that are built in to the Kubernetes control plane. When invoked with `--use-service-account-credentials`, kube-controller-manager starts each controller using a separate service account. Corresponding roles exist for each built-in controller, prefixed with `system:controller:`. If the controller manager is not started with `--use-service-account-credentials`, it runs all control loops using its own credential, which must be granted all the relevant roles. These roles include:

- system:controller:attachdetach-controller
- system:controller:certificate-controller
- system:controller:clusterrole-aggregation-controller
- system:controller:cronjob-controller
- system:controller:daemon-set-controller
- system:controller:deployment-controller
- system:controller:disruption-controller
- system:controller:endpoint-controller
- system:controller:expand-controller
- system:controller:generic-garbage-collector
- system:controller:horizontal-pod-autoscaler
- system:controller:job-controller
- system:controller:namespace-controller
- system:controller:node-controller
- system:controller:persistent-volume-binder
- system:controller:pod-garbage-collector
- system:controller:pv-protection-controller
- system:controller:pvc-protection-controller
- system:controller:replicaset-controller
- system:controller:replication-controller
- system:controller:resourcequota-controller
- system:controller:root-ca-cert-publisher
- system:controller:route-controller
- system:controller:service-account-controller
- system:controller:service-controller
- system:controller:statefulset-controller
- system:controller:ttl-controller

# Privilege escalation prevention and bootstrapping

The RBAC API prevents users from escalating privileges by editing roles or role bindings. Because this is enforced at the API level, it applies even when the RBAC authorizer is not in use.

## Restrictions on role creation or update

You can only create/update a role if at least one of the following things is true:

1. You already have all the permissions contained in the role, at the same scope as the object being modified (cluster-wide for a ClusterRole, within the same namespace or cluster-wide for a Role).
2. You are granted explicit permission to perform the `escalate` verb on the `roles` or `clusterroles` resource in the `rbac.authorization.k8s.io` API group.

For example, if user-1 does not have the ability to list Secrets cluster-wide, they cannot create a ClusterRole containing that permission. To allow a user to create/update roles:

1. Grant them a role that allows them to create/update Role or ClusterRole objects, as desired.
2. Grant them permission to include specific permissions in the roles they create/update:
  - implicitly, by giving them those permissions (if they attempt to create or modify a Role or ClusterRole with permissions they themselves have not been granted, the API request will be forbidden)
  - or explicitly allow specifying any permission in a Role or ClusterRole by giving them permission to perform the `escalate` verb on `roles` or `clusterroles` resources in the `rbac.authorization.k8s.io` API group

## Restrictions on role binding creation or update

You can only create/update a role binding if you already have all the permissions contained in the referenced role (at the same scope as the role binding) *or* if you have been authorized to perform the `bind` verb on the referenced role. For example, if user-1 does not have the ability to list Secrets cluster-wide, they cannot create a ClusterRoleBinding to a role that grants that permission. To allow a user to create/update role bindings:

1. Grant them a role that allows them to create/update RoleBinding or ClusterRoleBinding objects, as desired.
2. Grant them permissions needed to bind a particular role:
  - implicitly, by giving them the permissions contained in the role.
  - explicitly, by giving them permission to perform the `bind` verb on the particular Role (or ClusterRole).

For example, this ClusterRole and RoleBinding would allow user-1 to grant other users the `admin`, `edit`, and `view` roles in the namespace `user-1-namespace`:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: role-grantor
rules:
- apiGroups: ["rbac.authorization.k8s.io"]
```

```

resources: ["rolebindings"]
verbs: ["create"]
- apiGroups: ["rbac.authorization.k8s.io"]
resources: ["clusterroles"]
verbs: ["bind"]
omit resourceNames to allow binding any ClusterRole
resourceNames: ["admin","edit","view"]

apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
 name: role-grantor-binding
 namespace: user-1-namespace
roleRef:
 apiGroup: rbac.authorization.k8s.io
 kind: ClusterRole
 name: role-grantor
subjects:
- apiGroup: rbac.authorization.k8s.io
 kind: User
 name: user-1

```

When bootstrapping the first roles and role bindings, it is necessary for the initial user to grant permissions they do not yet have. To bootstrap initial roles and role bindings:

- Use a credential with the "system:masters" group, which is bound to the "cluster-admin" super-user role by the default bindings.

## Command-line utilities

### kubectl create role

Creates a Role object defining permissions within a single namespace. Examples:

- Create a Role named "pod-reader" that allows users to perform get, watch and list on pods:

```
kubectl create role pod-reader --verb=get --verb=list --verb=watch --resource=pods
```

- Create a Role named "pod-reader" with resourceNames specified:

```
kubectl create role pod-reader --verb=get --resource=pods --resource-name=readablepod
--resource-name=anotherpod
```

- Create a Role named "foo" with apiGroups specified:

```
kubectl create role foo --verb=get,list,watch --resource=replicasets.apps
```

- Create a Role named "foo" with subresource permissions:

```
kubectl create role foo --verb=get,list,watch --resource=pods,pods/status
```

- Create a Role named "my-component-lease-holder" with permissions to get/update a resource with a specific name:

```
kubectl create role my-component-lease-holder --verb=get,list,watch,update --resource=lease --resource-name=my-component
```

## kubectl create clusterrole

Creates a ClusterRole. Examples:

- Create a ClusterRole named "pod-reader" that allows user to perform get, watch and list on pods:

```
kubectl create clusterrole pod-reader --verb=get,list,watch --resource=pods
```

- Create a ClusterRole named "pod-reader" with resourceNames specified:

```
kubectl create clusterrole pod-reader --verb=get --resource=pods --resource-name=readablepod --resource-name=anotherpod
```

- Create a ClusterRole named "foo" with apiGroups specified:

```
kubectl create clusterrole foo --verb=get,list,watch --resource=replicasets.apps
```

- Create a ClusterRole named "foo" with subresource permissions:

```
kubectl create clusterrole foo --verb=get,list,watch --resource=pods,pods/status
```

- Create a ClusterRole named "foo" with nonResourceURL specified:

```
kubectl create clusterrole "foo" --verb=get --non-resource-url=/logs/*
```

- Create a ClusterRole named "monitoring" with an aggregationRule specified:

```
kubectl create clusterrole monitoring --aggregation-rule="rbac.example.com/aggregate-to-monitoring=true"
```

## kubectl create rolebinding

Grants a Role or ClusterRole within a specific namespace. Examples:

- Within the namespace "acme", grant the permissions in the "admin" ClusterRole to a user named "bob":

```
kubectl create rolebinding bob-admin-binding --clusterrole=admin --user=bob --namespace=acme
```

- Within the namespace "acme", grant the permissions in the "view" ClusterRole to the service account in the namespace "acme" named "myapp":

```
kubectl create rolebinding myapp-view-binding --clusterrole=view --serviceaccount=acme:myapp --namespace=acme
```

- Within the namespace "acme", grant the permissions in the "view" ClusterRole to a service account in the namespace "myappnamespace" named "myapp":

```
kubectl create rolebinding myappnamespace-myapp-view-binding --clusterrole=view --serviceaccount=myappnamespace:myapp --namespace=acme
```

## kubectl create clusterrolebinding

Grants a ClusterRole across the entire cluster (all namespaces). Examples:

- Across the entire cluster, grant the permissions in the "cluster-admin" ClusterRole to a user named "root":

```
kubectl create clusterrolebinding root-cluster-admin-binding --clusterrole=cluster-admin --user=root
```

- Across the entire cluster, grant the permissions in the "system:node-proxier" ClusterRole to a user named "system:kube-proxy":

```
kubectl create clusterrolebinding kube-proxy-binding --clusterrole=system:node-proxier --user=system:kube-proxy
```

- Across the entire cluster, grant the permissions in the "view" ClusterRole to a service account named "myapp" in the namespace "acme":

```
kubectl create clusterrolebinding myapp-view-binding --clusterrole=view --serviceaccount=acme:myapp
```

## kubectl auth reconcile

Creates or updates rbac.authorization.k8s.io/v1 API objects from a manifest file.

Missing objects are created, and the containing namespace is created for namespaced objects, if required.

Existing roles are updated to include the permissions in the input objects, and remove extra permissions if `--remove-extra-permissions` is specified.

Existing bindings are updated to include the subjects in the input objects, and remove extra subjects if `--remove-extra-subjects` is specified.

Examples:

- Test applying a manifest file of RBAC objects, displaying changes that would be made:

```
kubectl auth reconcile -f my-rbac-rules.yaml --dry-run=client
```

- Apply a manifest file of RBAC objects, preserving any extra permissions (in roles) and any extra subjects (in bindings):

```
kubectl auth reconcile -f my-rbac-rules.yaml
```

- Apply a manifest file of RBAC objects, removing any extra permissions (in roles) and any extra subjects (in bindings):

```
kubectl auth reconcile -f my-rbac-rules.yaml --remove-extra-subjects --remove-extra-permissions
```

# ServiceAccount permissions

Default RBAC policies grant scoped permissions to control-plane components, nodes, and controllers, but grant *no permissions* to service accounts outside the kube-system namespace (beyond discovery permissions given to all authenticated users).

This allows you to grant particular roles to particular ServiceAccounts as needed. Fine-grained role bindings provide greater security, but require more effort to administrate. Broader grants can give unnecessary (and potentially escalating) API access to ServiceAccounts, but are easier to administrate.

In order from most secure to least secure, the approaches are:

1. Grant a role to an application-specific service account (best practice)

This requires the application to specify a `serviceAccountName` in its pod spec, and for the service account to be created (via the API, application manifest, `kubectl create serviceaccount`, etc.).

For example, grant read-only permission within "my-namespace" to the "my-sa" service account:

```
kubectl create rolebinding my-sa-view \
 --clusterrole=view \
 --serviceaccount=my-namespace:my-sa \
 --namespace=my-namespace
```

2. Grant a role to the "default" service account in a namespace

If an application does not specify a `serviceAccountName`, it uses the "default" service account.

**Note:**

Permissions given to the "default" service account are available to any pod in the namespace that does not specify a `serviceAccountName`.

For example, grant read-only permission within "my-namespace" to the "default" service account:

```
kubectl create rolebinding default-view \
 --clusterrole=view \
 --serviceaccount=my-namespace:default \
 --namespace=my-namespace
```

Many [add-ons](#) run as the "default" service account in the kube-system namespace. To allow those add-ons to run with super-user access, grant cluster-admin permissions to the "default" service account in the kube-system namespace.

**Caution:**

Enabling this means the kube-system namespace contains Secrets that grant super-user access to your cluster's API.

```
kubectl create clusterrolebinding add-on-cluster-admin \
 --clusterrole=cluster-admin \
 --serviceaccount=kube-system:default
```

### 3. Grant a role to all service accounts in a namespace

If you want all applications in a namespace to have a role, no matter what service account they use, you can grant a role to the service account group for that namespace.

For example, grant read-only permission within "my-namespace" to all service accounts in that namespace:

```
kubectl create rolebinding serviceaccounts-view \
 --clusterrole=view \
 --group=system:serviceaccounts:my-namespace \
 --namespace=my-namespace
```

### 4. Grant a limited role to all service accounts cluster-wide (discouraged)

If you don't want to manage permissions per-namespace, you can grant a cluster-wide role to all service accounts.

For example, grant read-only permission across all namespaces to all service accounts in the cluster:

```
kubectl create clusterrolebinding serviceaccounts-view \
 --clusterrole=view \
 --group=system:serviceaccounts
```

### 5. Grant super-user access to all service accounts cluster-wide (strongly discouraged)

If you don't care about partitioning permissions at all, you can grant super-user access to all service accounts.

#### **Warning:**

This allows any application full access to your cluster, and also grants any user with read access to Secrets (or the ability to create any pod) full access to your cluster.

```
kubectl create clusterrolebinding serviceaccounts-cluster-admin \
 --clusterrole=cluster-admin \
 --group=system:serviceaccounts
```

## Write access for EndpointSlices and Endpoints

Kubernetes clusters created before Kubernetes v1.22 include write access to EndpointSlices (and Endpoints) in the aggregated "edit" and "admin" roles. As a mitigation for [CVE-2021-25740](#), this access is not part of the aggregated roles in clusters that you create using Kubernetes v1.22 or later.

Existing clusters that have been upgraded to Kubernetes v1.22 will not be subject to this change. The [CVE announcement](#) includes guidance for restricting this access in existing clusters.

If you want new clusters to retain this level of access in the aggregated roles, you can create the following ClusterRole:

[access/endpoints-aggregated.yaml](#)

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 annotations:
 kubernetes.io/description: |-
 Add endpoints write permissions to the edit and admin roles. This was
 removed by default in 1.22 because of CVE-2021-25740. See
 https://issue.k8s.io/103675. This can allow writers to direct LoadBalancer
 or Ingress implementations to expose backend IPs that would not otherwise
 be accessible, and can circumvent network policies or security controls
 intended to prevent/isolate access to those backends.
 EndpointSlices were never included in the edit or admin roles, so there
 is nothing to restore for the EndpointSlice API.
 labels:
 rbac.authorization.k8s.io/aggregate-to-edit: "true"
name: custom:aggregate-to-edit:endpoints # you can change this if you wish
rules:
- apiGroups: [""]
 resources: ["endpoints"]
 verbs: ["create", "delete", "deletecollection", "patch", "update"]
```

## Upgrading from ABAC

Clusters that originally ran older Kubernetes versions often used permissive ABAC policies, including granting full API access to all service accounts.

Default RBAC policies grant scoped permissions to control-plane components, nodes, and controllers, but grant *no permissions* to service accounts outside the kube-system namespace (beyond discovery permissions given to all authenticated users).

While far more secure, this can be disruptive to existing workloads expecting to automatically receive API permissions. Here are two approaches for managing this transition:

### Parallel authorizers

Run both the RBAC and ABAC authorizers, and specify a policy file that contains the [legacy ABAC policy](#):

```
--authorization-mode=...,RBAC,ABAC --authorization-policy-file=mypolicy.json
```

To explain that first command line option in detail: if earlier authorizers, such as Node, deny a request, then the RBAC authorizer attempts to authorize the API request. If RBAC also denies that API request, the ABAC authorizer is then run. This means that any request allowed by *either* the RBAC or ABAC policies is allowed.

When the kube-apiserver is run with a log level of 5 or higher for the RBAC component (`--vmodule=rbac*=5` or `--v=5`), you can see RBAC denials in the API server log (prefixed with

RBAC). You can use that information to determine which roles need to be granted to which users, groups, or service accounts.

Once you have [granted roles to service accounts](#) and workloads are running with no RBAC denial messages in the server logs, you can remove the ABAC authorizer.

## Permissive RBAC permissions

You can replicate a permissive ABAC policy using RBAC role bindings.

### Warning:

The following policy allows **ALL** service accounts to act as cluster administrators. Any application running in a container receives service account credentials automatically, and could perform any action against the API, including viewing secrets and modifying permissions. This is not a recommended policy.

```
kubectl create clusterrolebinding permissive-binding \
--clusterrole=cluster-admin \
--user=admin \
--user=kubelet \
--group=system:serviceaccounts
```

After you have transitioned to use RBAC, you should adjust the access controls for your cluster to ensure that these meet your information security needs.

# Using Node Authorization

Node authorization is a special-purpose authorization mode that specifically authorizes API requests made by kubelets.

## Overview

The Node authorizer allows a kubelet to perform API operations. This includes:

Read operations:

- services
- endpoints
- nodes
- pods
- secrets, configmaps, persistent volume claims and persistent volumes related to pods bound to the kubelet's node

Write operations:

- nodes and node status (enable the NodeRestriction admission plugin to limit a kubelet to modify its own node)
- pods and pod status (enable the NodeRestriction admission plugin to limit a kubelet to modify pods bound to itself)
- events

Auth-related operations:

- read/write access to the [CertificateSigningRequests API](#) for TLS bootstrapping
- the ability to create TokenReviews and SubjectAccessReviews for delegated authentication/authorization checks

In future releases, the node authorizer may add or remove permissions to ensure kubelets have the minimal set of permissions required to operate correctly.

In order to be authorized by the Node authorizer, kubelets must use a credential that identifies them as being in the system:nodes group, with a username of system:node:<nodeName>. This group and user name format match the identity created for each kubelet as part of [kubelet TLS bootstrapping](#).

The value of <nodeName> **must** match precisely the name of the node as registered by the kubelet. By default, this is the host name as provided by hostname, or overridden via the [kubelet option](#) `--hostname-override`. However, when using the `--cloud-provider` kubelet option, the specific hostname may be determined by the cloud provider, ignoring the local hostname and the `--hostname-override` option. For specifics about how the kubelet determines the hostname, see the [kubelet options reference](#).

To enable the Node authorizer, start the apiserver with `--authorization-mode=Node`.

To limit the API objects kubelets are able to write, enable the [NodeRestriction](#) admission plugin by starting the apiserver with `--enable-admission-plugins=...,NodeRestriction,...`

## Migration considerations

### Kubelets outside the system:nodes group

Kubelets outside the system:nodes group would not be authorized by the Node authorization mode, and would need to continue to be authorized via whatever mechanism currently authorizes them. The node admission plugin would not restrict requests from these kubelets.

### Kubelets with undifferentiated usernames

In some deployments, kubelets have credentials that place them in the system:nodes group, but do not identify the particular node they are associated with, because they do not have a username in the system:node:... format. These kubelets would not be authorized by the Node authorization mode, and would need to continue to be authorized via whatever mechanism currently authorizes them.

The NodeRestriction admission plugin would ignore requests from these kubelets, since the default node identifier implementation would not consider that a node identity.

## Webhook Mode

A WebHook is an HTTP callback: an HTTP POST that occurs when something happens; a simple event-notification via HTTP POST. A web application implementing WebHooks will POST a message to a URL when certain things happen.

When specified, mode Webhook causes Kubernetes to query an outside REST service when determining user privileges.

## Configuration File Format

Mode Webhook requires a file for HTTP configuration, specify by the `--authorization-webhook-config-file=SOME_FILENAME` flag.

The configuration file uses the [kubeconfig](#) file format. Within the file "users" refers to the API Server webhook and "clusters" refers to the remote service.

A configuration example which uses HTTPS client auth:

```
Kubernetes API version
apiVersion: v1
kind of the API object
kind: Config
clusters refers to the remote service.
clusters:
- name: name-of-remote-authz-service
 cluster:
 # CA for verifying the remote service.
 certificate-authority: /path/to/ca.pem
 # URL of remote service to query. Must use 'https'. May not include parameters.
 server: https://authz.example.com/authorize

users refers to the API Server's webhook configuration.
users:
- name: name-of-api-server
 user:
 client-certificate: /path/to/cert.pem # cert for the webhook plugin to use
 client-key: /path/to/key.pem # key matching the cert

kubeconfig files require a context. Provide one for the API Server.
current-context: webhook
contexts:
- context:
 cluster: name-of-remote-authz-service
 user: name-of-api-server
 name: webhook
```

## Request Payloads

When faced with an authorization decision, the API Server POSTs a JSON- serialized `authorization.k8s.io/v1beta1 SubjectAccessReview` object describing the action. This object contains fields describing the user attempting to make the request, and either details about the resource being accessed or requests attributes.

Note that webhook API objects are subject to the same [versioning compatibility rules](#) as other Kubernetes API objects. Implementers should be aware of looser compatibility promises for beta objects and check the "apiVersion" field of the request to ensure correct deserialization.

Additionally, the API Server must enable the `authorization.k8s.io/v1beta1` API extensions group (`--runtime-config=authorization.k8s.io/v1beta1=true`).

An example request body:

```
{
 "apiVersion": "authorization.k8s.io/v1beta1",
 "kind": "SubjectAccessReview",
 "spec": {
 "resourceAttributes": {
 "namespace": "kittensandponies",
 "verb": "get",
 "group": "unicorn.example.org",
 "resource": "pods"
 },
 "user": "jane",
 "group": [
 "group1",
 "group2"
]
 }
}
```

The remote service is expected to fill the `status` field of the request and respond to either allow or disallow access. The response body's `spec` field is ignored and may be omitted. A permissive response would return:

```
{
 "apiVersion": "authorization.k8s.io/v1beta1",
 "kind": "SubjectAccessReview",
 "status": {
 "allowed": true
 }
}
```

For disallowing access there are two methods.

The first method is preferred in most cases, and indicates the authorization webhook does not allow, or has "no opinion" about the request, but if other authorizers are configured, they are given a chance to allow the request. If there are no other authorizers, or none of them allow the request, the request is forbidden. The webhook would return:

```
{
 "apiVersion": "authorization.k8s.io/v1beta1",
 "kind": "SubjectAccessReview",
 "status": {
 "allowed": false,
 "reason": "user does not have read access to the namespace"
 }
}
```

The second method denies immediately, short-circuiting evaluation by other configured authorizers. This should only be used by webhooks that have detailed knowledge of the full authorizer configuration of the cluster. The webhook would return:

```
{
 "apiVersion": "authorization.k8s.io/v1beta1",
 "kind": "SubjectAccessReview",
 "status": {
 "allowed": false,
 "denied": true,
 "reason": "user does not have read access to the namespace"
 }
}
```

Access to non-resource paths are sent as:

```
{
 "apiVersion": "authorization.k8s.io/v1beta1",
 "kind": "SubjectAccessReview",
 "spec": {
 "nonResourceAttributes": {
 "path": "/debug",
 "verb": "get"
 },
 "user": "jane",
 "group": [
 "group1",
 "group2"
]
 }
}
```

Non-resource paths include: `/api`, `/apis`, `/metrics`, `/logs`, `/debug`, `/healthz`, `/livez`, `/openapi/v2`, `/readyz`, and `/version`. Clients require access to `/api`, `/api/*`, `/apis`, `/apis/*`, and `/version` to discover what resources and versions are present on the server. Access to other non-resource paths can be disallowed without restricting access to the REST api.

For further documentation refer to the `authorization.v1beta1` API objects and [webhook.go](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.16/#subjectaccessreview-authorization-k8s-io-v1beta1).

## Using ABAC Authorization

Attribute-based access control (ABAC) defines an access control paradigm whereby access rights are granted to users through the use of policies which combine attributes together.

### Policy File Format

To enable ABAC mode, specify `--authorization-policy-file=SOME_FILENAME` and `--authorization-mode=ABAC` on startup.

The file format is [one JSON object per line](#). There should be no enclosing list or map, only one map per line.

Each line is a "policy object", where each such object is a map with the following properties:

- Versioning properties:
  - `apiVersion`, type string; valid values are "abac.authorization.kubernetes.io/v1beta1". Allows versioning and conversion of the policy format.
  - `kind`, type string; valid values are "Policy". Allows versioning and conversion of the policy format.
- `spec` property set to a map with the following properties:
  - Subject-matching properties:
    - `user`, type string; the user-string from `--token-auth-file`. If you specify `user`, it must match the username of the authenticated user.
    - `group`, type string; if you specify `group`, it must match one of the groups of the authenticated user. `system:authenticated` matches all authenticated requests. `system:unauthenticated` matches all unauthenticated requests.
  - Resource-matching properties:
    - `apiGroup`, type string; an API group.
      - Ex: `apps`, `networking.k8s.io`
      - Wildcard: `*` matches all API groups.
    - `namespace`, type string; a namespace.
      - Ex: `kube-system`
      - Wildcard: `*` matches all resource requests.
    - `resource`, type string; a resource type
      - Ex: `pods`, `deployments`
      - Wildcard: `*` matches all resource requests.
  - Non-resource-matching properties:
    - `nonResourcePath`, type string; non-resource request paths.
      - Ex: `/version` or `/apis`
      - Wildcard:
        - `*` matches all non-resource requests.
        - `/foo/*` matches all subpaths of `/foo/`.
  - `readOnly`, type boolean, when true, means that the Resource-matching policy only applies to get, list, and watch operations, Non-resource-matching policy only applies to get operation.

#### Note:

An unset property is the same as a property set to the zero value for its type (e.g. empty string, 0, false). However, unset should be preferred for readability.

In the future, policies may be expressed in a JSON format, and managed via a REST interface.

## Authorization Algorithm

A request has attributes which correspond to the properties of a policy object.

When a request is received, the attributes are determined. Unknown attributes are set to the zero value of its type (e.g. empty string, 0, false).

A property set to `"**"` will match any value of the corresponding attribute.

The tuple of attributes is checked for a match against every policy in the policy file. If at least one line matches the request attributes, then the request is authorized (but may fail later validation).

To permit any authenticated user to do something, write a policy with the group property set to "system:authenticated".

To permit any unauthenticated user to do something, write a policy with the group property set to "system:unauthenticated".

To permit a user to do anything, write a policy with the apiGroup, namespace, resource, and nonResourcePath properties set to "\*".

## Kubectl

Kubectl uses the /api and /apis endpoints of apiserver to discover served resource types, and validates objects sent to the API by create/update operations using schema information located at /openapi/v2.

When using ABAC authorization, those special resources have to be explicitly exposed via the nonResourcePath property in a policy (see [examples](#) below):

- /api, /api/\*, /apis, and /apis/\* for API version negotiation.
- /version for retrieving the server version via kubectl version.
- /swaggerapi/\* for create/update operations.

To inspect the HTTP calls involved in a specific kubectl operation you can turn up the verbosity:

```
kubectl --v=8 version
```

## Examples

1. Alice can do anything to all resources:

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"user": "alice", "namespace": "*", "resource": "*", "apiGroup": "*"}}
```

2. The kubelet can read any pods:

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"user": "kubelet", "namespace": "*", "resource": "pods", "readonly": true}}
```

3. The kubelet can read and write events:

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"user": "kubelet", "namespace": "*", "resource": "events"}}
```

4. Bob can just read pods in namespace "projectCaribou":

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"user": "bob", "namespace": "projectCaribou", "resource": "pods", "readonly": true}}
```

Anyone can make read-only requests to all non-resource paths:

5.

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec":
 {"group": "system:authenticated", "readonly": true, "nonResourcePath": "**"}}
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"group
 ": "system:unauthenticated", "readonly": true, "nonResourcePath": "**"}}
```

[Complete file example](#)

## A quick note on service accounts

Every service account has a corresponding ABAC username, and that service account's username is generated according to the naming convention:

```
system:serviceaccount:<namespace>:<serviceaccountname>
```

Creating a new namespace leads to the creation of a new service account in the following format:

```
system:serviceaccount:<namespace>:default
```

For example, if you wanted to grant the default service account (in the kube-system namespace) full privilege to the API using ABAC, you would add this line to your policy file:

```
{"apiVersion": "abac.authorization.kubernetes.io/v1beta1", "kind": "Policy", "spec": {"user": "system:se
rviceaccount:kube-system:default", "namespace": "**", "resource": "**", "apiGroup": "**"}}
```

The apiserver will need to be restarted to pick up the new policy lines.

# Admission Controllers Reference

This page provides an overview of Admission Controllers.

## What are they?

An *admission controller* is a piece of code that intercepts requests to the Kubernetes API server prior to persistence of the object, but after the request is authenticated and authorized.

Admission controllers may be *validating*, *mutating*, or both. Mutating controllers may modify objects related to the requests they admit; validating controllers may not.

Admission controllers limit requests to create, delete, modify objects. Admission controllers can also block custom verbs, such as a request connect to a Pod via an API server proxy. Admission controllers do *not* (and cannot) block requests to read (**get**, **watch** or **list**) objects.

The admission controllers in Kubernetes 1.30 consist of the [list](#) below, are compiled into the kube-apiserver binary, and may only be configured by the cluster administrator. In that list, there are two special controllers: MutatingAdmissionWebhook and ValidatingAdmissionWebhook. These execute the mutating and validating (respectively) [admission control webhooks](#) which are configured in the API.

## Admission control phases

The admission control process proceeds in two phases. In the first phase, mutating admission controllers are run. In the second phase, validating admission controllers are run. Note again that some of the controllers are both.

If any of the controllers in either phase reject the request, the entire request is rejected immediately and an error is returned to the end-user.

Finally, in addition to sometimes mutating the object in question, admission controllers may sometimes have side effects, that is, mutate related resources as part of request processing. Incrementing quota usage is the canonical example of why this is necessary. Any such side-effect needs a corresponding reclamation or reconciliation process, as a given admission controller does not know for sure that a given request will pass all of the other admission controllers.

## Why do I need them?

Several important features of Kubernetes require an admission controller to be enabled in order to properly support the feature. As a result, a Kubernetes API server that is not properly configured with the right set of admission controllers is an incomplete server and will not support all the features you expect.

## How do I turn on an admission controller?

The Kubernetes API server flag `enable-admission-plugins` takes a comma-delimited list of admission control plugins to invoke prior to modifying objects in the cluster. For example, the following command line enables the `NamespaceLifecycle` and the `LimitRanger` admission control plugins:

```
kube-apiserver --enable-admission-plugins=NamespaceLifecycle,LimitRanger ...
```

### Note:

Depending on the way your Kubernetes cluster is deployed and how the API server is started, you may need to apply the settings in different ways. For example, you may have to modify the systemd unit file if the API server is deployed as a systemd service, you may modify the manifest file for the API server if Kubernetes is deployed in a self-hosted way.

## How do I turn off an admission controller?

The Kubernetes API server flag `disable-admission-plugins` takes a comma-delimited list of admission control plugins to be disabled, even if they are in the list of plugins enabled by default.

```
kube-apiserver --disable-admission-plugins=PodNodeSelector,AlwaysDeny ...
```

## Which plugins are enabled by default?

To see which admission plugins are enabled:

```
kube-apiserver -h | grep enable-admission-plugins
```

In Kubernetes 1.30, the default ones are:

CertificateApproval, CertificateSigning, CertificateSubjectRestriction, DefaultIngressClass, DefaultStorageClass, DefaultTolerationSeconds, LimitRanger, MutatingAdmissionWebhook, NamespaceLifecycle, PersistentVolumeClaimResize, PodSecurity, Priority, ResourceQuota, RuntimeClass, ServiceAccount, StorageObjectInUseProtection, TaintNodesByCondition, ValidatingAdmissionPolicy, ValidatingAdmissionWebhook

#### Note:

The [ValidatingAdmissionPolicy](#) admission plugin is enabled by default, but is only active if you enable the ValidatingAdmissionPolicy [feature gate](#) **and** the admissionregistration.k8s.io/v1alpha1 API.

## What does each admission controller do?

### AlwaysAdmit

FEATURE STATE: Kubernetes v1.13 [deprecated]

**Type:** Validating.

This admission controller allows all pods into the cluster. It is **deprecated** because its behavior is the same as if there were no admission controller at all.

### AlwaysDeny

FEATURE STATE: Kubernetes v1.13 [deprecated]

**Type:** Validating.

Rejects all requests. AlwaysDeny is **deprecated** as it has no real meaning.

### AlwaysPullImages

**Type:** Mutating and Validating.

This admission controller modifies every new Pod to force the image pull policy to Always. This is useful in a multitenant cluster so that users can be assured that their private images can only be used by those who have the credentials to pull them. Without this admission controller, once an image has been pulled to a node, any pod from any user can use it by knowing the image's name (assuming the Pod is scheduled onto the right node), without any authorization check against the image. When this admission controller is enabled, images are always pulled prior to starting containers, which means valid credentials are required.

### CertificateApproval

**Type:** Validating.

This admission controller observes requests to approve `CertificateSigningRequest` resources and performs additional authorization checks to ensure the approving user has permission to **approve** certificate requests with the `spec.signerName` requested on the `CertificateSigningRequest` resource.

See [Certificate Signing Requests](#) for more information on the permissions required to perform different actions on `CertificateSigningRequest` resources.

## CertificateSigning

**Type:** Validating.

This admission controller observes updates to the `status.certificate` field of `CertificateSigningRequest` resources and performs an additional authorization checks to ensure the signing user has permission to **sign** certificate requests with the `spec.signerName` requested on the `CertificateSigningRequest` resource.

See [Certificate Signing Requests](#) for more information on the permissions required to perform different actions on `CertificateSigningRequest` resources.

## CertificateSubjectRestriction

**Type:** Validating.

This admission controller observes creation of `CertificateSigningRequest` resources that have a `spec.signerName` of `kubernetes.io/kube-apiserver-client`. It rejects any request that specifies a 'group' (or 'organization attribute') of `system:masters`.

## DefaultIngressClass

**Type:** Mutating.

This admission controller observes creation of `Ingress` objects that do not request any specific ingress class and automatically adds a default ingress class to them. This way, users that do not request any special ingress class do not need to care about them at all and they will get the default one.

This admission controller does not do anything when no default ingress class is configured. When more than one ingress class is marked as default, it rejects any creation of `Ingress` with an error and an administrator must revisit their `IngressClass` objects and mark only one as default (with the annotation `"ingressclass.kubernetes.io/is-default-class"`). This admission controller ignores any `Ingress` updates; it acts only on creation.

See the [Ingress](#) documentation for more about ingress classes and how to mark one as default.

## DefaultStorageClass

**Type:** Mutating.

This admission controller observes creation of `PersistentVolumeClaim` objects that do not request any specific storage class and automatically adds a default storage class to them. This way, users that do not request any special storage class do not need to care about them at all and they will get the default one.

This admission controller does not do anything when no default storage class is configured. When more than one storage class is marked as default, it rejects any creation of PersistentVolumeClaim with an error and an administrator must revisit their StorageClass objects and mark only one as default. This admission controller ignores any PersistentVolumeClaim updates; it acts only on creation.

See [persistent volume](#) documentation about persistent volume claims and storage classes and how to mark a storage class as default.

## DefaultTolerationSeconds

**Type:** Mutating.

This admission controller sets the default forgiveness toleration for pods to tolerate the taints notready:NoExecute and unreachable:NoExecute based on the k8s-apiserver input parameters default-not-ready-toleration-seconds and default-unreachable-toleration-seconds if the pods don't already have toleration for taints node.kubernetes.io/not-ready:NoExecute or node.kubernetes.io/unreachable:NoExecute. The default value for default-not-ready-toleration-seconds and default-unreachable-toleration-seconds is 5 minutes.

## DenyServiceExternalIPs

**Type:** Validating.

This admission controller rejects all net-new usage of the Service field externalIPs. This feature is very powerful (allows network traffic interception) and not well controlled by policy. When enabled, users of the cluster may not create new Services which use externalIPs and may not add new values to externalIPs on existing Service objects. Existing uses of externalIPs are not affected, and users may remove values from externalIPs on existing Service objects.

Most users do not need this feature at all, and cluster admins should consider disabling it. Clusters that do need to use this feature should consider using some custom policy to manage usage of it.

This admission controller is disabled by default.

## EventRateLimit

FEATURE STATE: Kubernetes v1.13 [alpha]

**Type:** Validating.

This admission controller mitigates the problem where the API server gets flooded by requests to store new Events. The cluster admin can specify event rate limits by:

- Enabling the EventRateLimit admission controller;
- Referencing an EventRateLimit configuration file from the file provided to the API server's command line flag --admission-control-config-file:

```
apiVersion: apiserver.config.k8s.io/v1
kind: AdmissionConfiguration
plugins:
- name: EventRateLimit
```

```
path: eventconfig.yaml
```

```
...
```

There are four types of limits that can be specified in the configuration:

- Server: All Event requests (creation or modifications) received by the API server share a single bucket.
- Namespace: Each namespace has a dedicated bucket.
- User: Each user is allocated a bucket.
- SourceAndObject: A bucket is assigned by each combination of source and involved object of the event.

Below is a sample eventconfig.yaml for such a configuration:

```
apiVersion: eventratelimit.admission.k8s.io/v1alpha1
kind: Configuration
limits:
- type: Namespace
 qps: 50
 burst: 100
 cacheSize: 2000
- type: User
 qps: 10
 burst: 50
```

See the [EventRateLimit Config API \(v1alpha1\)](#) for more details.

This admission controller is disabled by default.

## ExtendedResourceToleration

**Type:** Mutating.

This plug-in facilitates creation of dedicated nodes with extended resources. If operators want to create dedicated nodes with extended resources (like GPUs, FPGAs etc.), they are expected to [taint the node](#) with the extended resource name as the key. This admission controller, if enabled, automatically adds tolerations for such taints to pods requesting extended resources, so users don't have to manually add these tolerations.

This admission controller is disabled by default.

## ImagePolicyWebhook

**Type:** Validating.

The ImagePolicyWebhook admission controller allows a backend webhook to make admission decisions.

This admission controller is disabled by default.

## Configuration file format

ImagePolicyWebhook uses a configuration file to set options for the behavior of the backend. This file may be json or yaml and has the following format:

```
imagePolicy:
 kubeConfigFile: /path/to/kubeconfig/for/backend
 # time in s to cache approval
 allowTTL: 50
 # time in s to cache denial
 denyTTL: 50
 # time in ms to wait between retries
 retryBackoff: 500
 # determines behavior if the webhook backend fails
 defaultAllow: true
```

Reference the ImagePolicyWebhook configuration file from the file provided to the API server's command line flag `--admission-control-config-file`:

```
apiVersion: apiserver.config.k8s.io/v1
kind: AdmissionConfiguration
plugins:
 - name: ImagePolicyWebhook
 path: imagepolicyconfig.yaml
...
```

Alternatively, you can embed the configuration directly in the file:

```
apiVersion: apiserver.config.k8s.io/v1
kind: AdmissionConfiguration
plugins:
 - name: ImagePolicyWebhook
 configuration:
 imagePolicy:
 kubeConfigFile: <path-to-kubeconfig-file>
 allowTTL: 50
 denyTTL: 50
 retryBackoff: 500
 defaultAllow: true
```

The ImagePolicyWebhook config file must reference a [kubeconfig](#) formatted file which sets up the connection to the backend. It is required that the backend communicate over TLS.

The kubeconfig file's `cluster` field must point to the remote service, and the `user` field must contain the returned authorizer.

```
clusters refers to the remote service.
clusters:
 - name: name-of-remote-imagepolicy-service
 cluster:
 certificate-authority: /path/to/ca.pem # CA for verifying the remote service.
 server: https://images.example.com/policy # URL of remote service to query. Must use 'https'.
```

```
users refers to the API server's webhook configuration.
users:
- name: name-of-api-server
 user:
 client-certificate: /path/to/cert.pem # cert for the webhook admission controller to use
 client-key: /path/to/key.pem # key matching the cert
```

For additional HTTP configuration, refer to the [kubecfg](#) documentation.

## Request payloads

When faced with an admission decision, the API Server POSTs a JSON serialized `imagepolicy.k8s.io/v1alpha1 ImageReview` object describing the action. This object contains fields describing the containers being admitted, as well as any pod annotations that match `*.image-policy.k8s.io/*`.

### Note:

The webhook API objects are subject to the same versioning compatibility rules as other Kubernetes API objects. Implementers should be aware of looser compatibility promises for alpha objects and check the `apiVersion` field of the request to ensure correct deserialization. Additionally, the API Server must enable the `imagepolicy.k8s.io/v1alpha1` API extensions group (`--runtime-config=imagepolicy.k8s.io/v1alpha1=true`).

An example request body:

```
{
 "apiVersion": "imagepolicy.k8s.io/v1alpha1",
 "kind": "ImageReview",
 "spec": {
 "containers": [
 {
 "image": "myrepo/myimage:v1"
 },
 {
 "image": "myrepo/
myimage@sha256:beb6bd6a68f114c1dc2ea4b28db81bdf91de202a9014972bec5e4d9171d90ed"
 }
],
 "annotations": {
 "mycluster.image-policy.k8s.io/ticket-1234": "break-glass"
 },
 "namespace": "mynamespace"
 }
}
```

The remote service is expected to fill the `status` field of the request and respond to either allow or disallow access. The response body's `spec` field is ignored, and may be omitted. A permissive response would return:

```
{
 "apiVersion": "imagepolicy.k8s.io/v1alpha1",
 "kind": "ImageReview",
```

```
"status": {
 "allowed": true
}
```

To disallow access, the service would return:

```
{
 "apiVersion": "imagepolicy.k8s.io/v1alpha1",
 "kind": "ImageReview",
 "status": {
 "allowed": false,
 "reason": "image currently blacklisted"
 }
}
```

For further documentation refer to the [imagepolicy.v1alpha1 API](#).

## Extending with Annotations

All annotations on a Pod that match `*.image-policy.k8s.io/*` are sent to the webhook. Sending annotations allows users who are aware of the image policy backend to send extra information to it, and for different backends implementations to accept different information.

Examples of information you might put here are:

- request to "break glass" to override a policy, in case of emergency.
- a ticket number from a ticket system that documents the break-glass request
- provide a hint to the policy server as to the imageID of the image being provided, to save it a lookup

In any case, the annotations are provided by the user and are not validated by Kubernetes in any way.

## LimitPodHardAntiAffinityTopology

**Type:** Validating.

This admission controller denies any pod that defines AntiAffinity topology key other than `kubernetes.io/hostname` in `requiredDuringSchedulingRequiredDuringExecution`.

This admission controller is disabled by default.

## LimitRanger

**Type:** Mutating and Validating.

This admission controller will observe the incoming request and ensure that it does not violate any of the constraints enumerated in the `LimitRange` object in a Namespace. If you are using `LimitRange` objects in your Kubernetes deployment, you **MUST** use this admission controller to enforce those constraints. `LimitRanger` can also be used to apply default resource requests to Pods that don't specify any; currently, the default `LimitRanger` applies a 0.1 CPU requirement to all Pods in the default namespace.

See the [LimitRange API reference](#) and the [example of LimitRange](#) for more details.

## MutatingAdmissionWebhook

**Type:** Mutating.

This admission controller calls any mutating webhooks which match the request. Matching webhooks are called in serial; each one may modify the object if it desires.

This admission controller (as implied by the name) only runs in the mutating phase.

If a webhook called by this has side effects (for example, decrementing quota) it *must* have a reconciliation system, as it is not guaranteed that subsequent webhooks or validating admission controllers will permit the request to finish.

If you disable the MutatingAdmissionWebhook, you must also disable the MutatingWebhookConfiguration object in the admissionregistration.k8s.io/v1 group/version via the `--runtime-config` flag, both are on by default.

### Use caution when authoring and installing mutating webhooks

- Users may be confused when the objects they try to create are different from what they get back.
- Built in control loops may break when the objects they try to create are different when read back.
  - Setting originally unset fields is less likely to cause problems than overwriting fields set in the original request. Avoid doing the latter.
- Future changes to control loops for built-in resources or third-party resources may break webhooks that work well today. Even when the webhook installation API is finalized, not all possible webhook behaviors will be guaranteed to be supported indefinitely.

## NamespaceAutoProvision

**Type:** Mutating.

This admission controller examines all incoming requests on namespaced resources and checks if the referenced namespace does exist. It creates a namespace if it cannot be found. This admission controller is useful in deployments that do not want to restrict creation of a namespace prior to its usage.

## NamespaceExists

**Type:** Validating.

This admission controller checks all requests on namespaced resources other than Namespace itself. If the namespace referenced from a request doesn't exist, the request is rejected.

## NamespaceLifecycle

**Type:** Validating.

This admission controller enforces that a Namespace that is undergoing termination cannot have new objects created in it, and ensures that requests in a non-existent Namespace are rejected. This admission controller also prevents deletion of three system reserved namespaces default, kube-system, kube-public.

A Namespace deletion kicks off a sequence of operations that remove all objects (pods, services, etc.) in that namespace. In order to enforce integrity of that process, we strongly recommend running this admission controller.

## NodeRestriction

**Type:** Validating.

This admission controller limits the Node and Pod objects a kubelet can modify. In order to be limited by this admission controller, kubelets must use credentials in the system:nodes group, with a username in the form system:node:<nodeName>. Such kubelets will only be allowed to modify their own Node API object, and only modify Pod API objects that are bound to their node. kubelets are not allowed to update or remove taints from their Node API object.

The NodeRestriction admission plugin prevents kubelets from deleting their Node API object, and enforces kubelet modification of labels under the kubernetes.io/ or k8s.io/ prefixes as follows:

- **Prevents** kubelets from adding/removing/updating labels with a node-restriction.kubernetes.io/ prefix. This label prefix is reserved for administrators to label their Node objects for workload isolation purposes, and kubelets will not be allowed to modify labels with that prefix.
- **Allows** kubelets to add/remove/update these labels and label prefixes:
  - kubernetes.io/hostname
  - kubernetes.io/arch
  - kubernetes.io/os
  - beta.kubernetes.io/instance-type
  - node.kubernetes.io/instance-type
  - failure-domain.beta.kubernetes.io/region (deprecated)
  - failure-domain.beta.kubernetes.io/zone (deprecated)
  - topology.kubernetes.io/region
  - topology.kubernetes.io/zone
  - kubelet.kubernetes.io/-prefixed labels
  - node.kubernetes.io/-prefixed labels

Use of any other labels under the kubernetes.io or k8s.io prefixes by kubelets is reserved, and may be disallowed or allowed by the NodeRestriction admission plugin in the future.

Future versions may add additional restrictions to ensure kubelets have the minimal set of permissions required to operate correctly.

## OwnerReferencesPermissionEnforcement

**Type:** Validating.

This admission controller protects the access to the metadata.ownerReferences of an object so that only users with **delete** permission to the object can change it. This admission controller also protects the access to metadata.ownerReferences[x].blockOwnerDeletion of an object, so

that only users with **update** permission to the finalizers subresource of the referenced *owner* can change it.

## PersistentVolumeClaimResize

FEATURE STATE: Kubernetes v1.24 [stable]

**Type:** Validating.

This admission controller implements additional validations for checking incoming PersistentVolumeClaim resize requests.

Enabling the PersistentVolumeClaimResize admission controller is recommended. This admission controller prevents resizing of all claims by default unless a claim's StorageClass explicitly enables resizing by setting allowVolumeExpansion to true.

For example: all PersistentVolumeClaims created from the following StorageClass support volume expansion:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
 name: gluster-vol-default
provisioner: kubernetes.io/glusterfs
parameters:
 resturl: "http://192.168.10.100:8080"
 restuser: ""
 secretNamespace: ""
 secretName: ""
allowVolumeExpansion: true
```

For more information about persistent volume claims, see [PersistentVolumeClaims](#).

## PersistentVolumeLabel

FEATURE STATE: Kubernetes v1.13 [deprecated]

**Type:** Mutating.

This admission controller automatically attaches region or zone labels to PersistentVolumes as defined by the cloud provider (for example, Azure or GCP). It helps ensure the Pods and the PersistentVolumes mounted are in the same region and/or zone. If the admission controller doesn't support automatic labelling your PersistentVolumes, you may need to add the labels manually to prevent pods from mounting volumes from a different zone. PersistentVolumeLabel is **deprecated** as labeling for persistent volumes has been taken over by the [cloud-controller-manager](#).

This admission controller is disabled by default.

## PodNodeSelector

FEATURE STATE: Kubernetes v1.5 [alpha]

**Type:** Validating.

This admission controller defaults and limits what node selectors may be used within a namespace by reading a namespace annotation and a global configuration.

This admission controller is disabled by default.

### Configuration file format

PodNodeSelector uses a configuration file to set options for the behavior of the backend. Note that the configuration file format will move to a versioned file in a future release. This file may be json or yaml and has the following format:

```
podNodeSelectorPluginConfig:
 clusterDefaultNodeSelector: name-of-node-selector
 namespace1: name-of-node-selector
 namespace2: name-of-node-selector
```

Reference the PodNodeSelector configuration file from the file provided to the API server's command line flag `--admission-control-config-file`:

```
apiVersion: apiserver.config.k8s.io/v1
kind: AdmissionConfiguration
plugins:
- name: PodNodeSelector
 path: podnodeselector.yaml
...
```

### Configuration Annotation Format

PodNodeSelector uses the annotation key `scheduler.alpha.kubernetes.io/node-selector` to assign node selectors to namespaces.

```
apiVersion: v1
kind: Namespace
metadata:
 annotations:
 scheduler.alpha.kubernetes.io/node-selector: name-of-node-selector
 name: namespace3
```

### Internal Behavior

This admission controller has the following behavior:

1. If the Namespace has an annotation with a key `scheduler.alpha.kubernetes.io/node-selector`, use its value as the node selector.
2. If the namespace lacks such an annotation, use the `clusterDefaultNodeSelector` defined in the PodNodeSelector plugin configuration file as the node selector.
3. Evaluate the pod's node selector against the namespace node selector for conflicts. Conflicts result in rejection.
4. Evaluate the pod's node selector against the namespace-specific allowed selector defined the plugin configuration file. Conflicts result in rejection.

**Note:**

PodNodeSelector allows forcing pods to run on specifically labeled nodes. Also see the PodTolerationRestriction admission plugin, which allows preventing pods from running on specifically tainted nodes.

## PodSecurity

FEATURE STATE: Kubernetes v1.25 [stable]

**Type:** Validating.

The PodSecurity admission controller checks new Pods before they are admitted, determines if it should be admitted based on the requested security context and the restrictions on permitted [Pod Security Standards](#) for the namespace that the Pod would be in.

See the [Pod Security Admission](#) documentation for more information.

PodSecurity replaced an older admission controller named PodSecurityPolicy.

## PodTolerationRestriction

FEATURE STATE: Kubernetes v1.7 [alpha]

**Type:** Mutating and Validating.

The PodTolerationRestriction admission controller verifies any conflict between tolerations of a pod and the tolerations of its namespace. It rejects the pod request if there is a conflict. It then merges the tolerations annotated on the namespace into the tolerations of the pod. The resulting tolerations are checked against a list of allowed tolerations annotated to the namespace. If the check succeeds, the pod request is admitted otherwise it is rejected.

If the namespace of the pod does not have any associated default tolerations or allowed tolerations annotated, the cluster-level default tolerations or cluster-level list of allowed tolerations are used instead if they are specified.

Tolerations to a namespace are assigned via the scheduler.alpha.kubernetes.io/defaultTolerations annotation key. The list of allowed tolerations can be added via the scheduler.alpha.kubernetes.io/tolerationsWhitelist annotation key.

Example for namespace annotations:

```
apiVersion: v1
kind: Namespace
metadata:
 name: apps-that-need-nodes-exclusively
 annotations:
 scheduler.alpha.kubernetes.io/defaultTolerations: '[{"operator": "Exists", "effect": "NoSchedule", "key": "dedicated-node"}]'
 scheduler.alpha.kubernetes.io/tolerationsWhitelist: '[{"operator": "Exists", "effect": "NoSchedule", "key": "dedicated-node"}]'
```

This admission controller is disabled by default.

## Priority

**Type:** Mutating and Validating.

The priority admission controller uses the `priorityClassName` field and populates the integer value of the priority. If the priority class is not found, the Pod is rejected.

## ResourceQuota

**Type:** Validating.

This admission controller will observe the incoming request and ensure that it does not violate any of the constraints enumerated in the ResourceQuota object in a Namespace. If you are using ResourceQuota objects in your Kubernetes deployment, you **MUST** use this admission controller to enforce quota constraints.

See the [ResourceQuota API reference](#) and the [example of Resource Quota](#) for more details.

## RuntimeClass

**Type:** Mutating and Validating.

If you define a RuntimeClass with [Pod overhead](#) configured, this admission controller checks incoming Pods. When enabled, this admission controller rejects any Pod create requests that have the overhead already set. For Pods that have a RuntimeClass configured and selected in their `.spec`, this admission controller sets `.spec.overhead` in the Pod based on the value defined in the corresponding RuntimeClass.

See also [Pod Overhead](#) for more information.

## ServiceAccount

**Type:** Mutating and Validating.

This admission controller implements automation for [serviceAccounts](#). The Kubernetes project strongly recommends enabling this admission controller. You should enable this admission controller if you intend to make any use of Kubernetes ServiceAccount objects.

Regarding the annotation `kubernetes.io/enforce-mountable-secrets`: While the annotation's name suggests it only concerns the mounting of Secrets, its enforcement also extends to other ways Secrets are used in the context of a Pod. Therefore, it is crucial to ensure that all the referenced secrets are correctly specified in the ServiceAccount.

## StorageObjectInUseProtection

**Type:** Mutating.

The StorageObjectInUseProtection plugin adds the `kubernetes.io/pvc-protection` or `kubernetes.io/pv-protection` finalizers to newly created Persistent Volume Claims (PVCs) or Persistent Volumes (PV). In case a user deletes a PVC or PV the PVC or PV is not removed until the finalizer is removed from the PVC or PV by PVC or PV Protection Controller. Refer to the [Storage Object in Use Protection](#) for more detailed information.

## TaintNodesByCondition

**Type:** Mutating.

This admission controller [taints](#) newly created Nodes as NotReady and NoSchedule. That tainting avoids a race condition that could cause Pods to be scheduled on new Nodes before their taints were updated to accurately reflect their reported conditions.

## ValidatingAdmissionPolicy

**Type:** Validating.

[This admission controller](#) implements the CEL validation for incoming matched requests. It is enabled when both feature gate validatingadmissionpolicy and admissionregistration.k8s.io/v1alpha1 group/version are enabled. If any of the ValidatingAdmissionPolicy fails, the request fails.

## ValidatingAdmissionWebhook

**Type:** Validating.

This admission controller calls any validating webhooks which match the request. Matching webhooks are called in parallel; if any of them rejects the request, the request fails. This admission controller only runs in the validation phase; the webhooks it calls may not mutate the object, as opposed to the webhooks called by the MutatingAdmissionWebhook admission controller.

If a webhook called by this has side effects (for example, decrementing quota) it *must* have a reconciliation system, as it is not guaranteed that subsequent webhooks or other validating admission controllers will permit the request to finish.

If you disable the ValidatingAdmissionWebhook, you must also disable the ValidatingWebhookConfiguration object in the admissionregistration.k8s.io/v1 group/version via the `--runtime-config` flag.

## Is there a recommended set of admission controllers to use?

Yes. The recommended admission controllers are enabled by default (shown [here](#)), so you do not need to explicitly specify them. You can enable additional admission controllers beyond the default set using the `--enable-admission-plugins` flag (**order doesn't matter**).

## Dynamic Admission Control

In addition to [compiled-in admission plugins](#), admission plugins can be developed as extensions and run as webhooks configured at runtime. This page describes how to build, configure, use, and monitor admission webhooks.

# What are admission webhooks?

Admission webhooks are HTTP callbacks that receive admission requests and do something with them. You can define two types of admission webhooks, [validating admission webhook](#) and [mutating admission webhook](#). Mutating admission webhooks are invoked first, and can modify objects sent to the API server to enforce custom defaults. After all object modifications are complete, and after the incoming object is validated by the API server, validating admission webhooks are invoked and can reject requests to enforce custom policies.

## Note:

Admission webhooks that need to guarantee they see the final state of the object in order to enforce policy should use a validating admission webhook, since objects can be modified after being seen by mutating webhooks.

## Experimenting with admission webhooks

Admission webhooks are essentially part of the cluster control-plane. You should write and deploy them with great caution. Please read the [user guides](#) for instructions if you intend to write/deploy production-grade admission webhooks. In the following, we describe how to quickly experiment with admission webhooks.

### Prerequisites

- Ensure that MutatingAdmissionWebhook and ValidatingAdmissionWebhook admission controllers are enabled. [Here](#) is a recommended set of admission controllers to enable in general.
- Ensure that the admissionregistration.k8s.io/v1 API is enabled.

### Write an admission webhook server

Please refer to the implementation of the [admission webhook server](#) that is validated in a Kubernetes e2e test. The webhook handles the AdmissionReview request sent by the API servers, and sends back its decision as an AdmissionReview object in the same version it received.

See the [webhook request](#) section for details on the data sent to webhooks.

See the [webhook response](#) section for the data expected from webhooks.

The example admission webhook server leaves the ClientAuth field [empty](#), which defaults to NoClientCert. This means that the webhook server does not authenticate the identity of the clients, supposedly API servers. If you need mutual TLS or other ways to authenticate the clients, see how to [authenticate API servers](#).

### Deploy the admission webhook service

The webhook server in the e2e test is deployed in the Kubernetes cluster, via the [deployment API](#). The test also creates a [service](#) as the front-end of the webhook server. See [code](#).

You may also deploy your webhooks outside of the cluster. You will need to update your webhook configurations accordingly.

## Configure admission webhooks on the fly

You can dynamically configure what resources are subject to what admission webhooks via [ValidatingWebhookConfiguration](#) or [MutatingWebhookConfiguration](#).

The following is an example ValidatingWebhookConfiguration, a mutating webhook configuration is similar. See the [webhook configuration](#) section for details about each config field.

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
metadata:
 name: "pod-policy.example.com"
webhooks:
- name: "pod-policy.example.com"
 rules:
 - apiGroups: [""]
 apiVersions: ["v1"]
 operations: ["CREATE"]
 resources: ["pods"]
 scope: "Namespaced"
 clientConfig:
 service:
 namespace: "example-namespace"
 name: "example-service"
 caBundle: <CA_BUNDLE>
 admissionReviewVersions: ["v1"]
 sideEffects: None
 timeoutSeconds: 5
```

### Note:

You must replace the <CA\_BUNDLE> in the above example by a valid CA bundle which is a PEM-encoded (field value is Base64 encoded) CA bundle for validating the webhook's server certificate.

The scope field specifies if only cluster-scoped resources ("Cluster") or namespace-scoped resources ("Namespaced") will match this rule. "\*" means that there are no scope restrictions.

### Note:

When using clientConfig.service, the server cert must be valid for <svc\_name>.<svc\_namespace>.svc.

### Note:

Default timeout for a webhook call is 10 seconds, You can set the timeout and it is encouraged to use a short timeout for webhooks. If the webhook call times out, the request is handled according to the webhook's failure policy.

When an API server receives a request that matches one of the rules, the API server sends an admissionReview request to webhook as specified in the clientConfig.

After you create the webhook configuration, the system will take a few seconds to honor the new configuration.

## Authenticate API servers

If your admission webhooks require authentication, you can configure the API servers to use basic auth, bearer token, or a cert to authenticate itself to the webhooks. There are three steps to complete the configuration.

- When starting the API server, specify the location of the admission control configuration file via the --admission-control-config-file flag.
- In the admission control configuration file, specify where the MutatingAdmissionWebhook controller and ValidatingAdmissionWebhook controller should read the credentials. The credentials are stored in kubeConfig files (yes, the same schema that's used by kubectl), so the field name is kubeConfigFile. Here is an example admission control configuration file:
- [apiserver.config.k8s.io/v1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#apiserverconfig-k8s-io-v1)
- [apiserver.k8s.io/v1alpha1](https://kubernetes.io/docs/reference/generated/kubernetes-api/v1.17/#apiserverconfig-k8s-io-v1alpha1)

```
apiVersion: apiserver.config.k8s.io/v1
kind: AdmissionConfiguration
plugins:
- name: ValidatingAdmissionWebhook
 configuration:
 apiVersion: apiserver.config.k8s.io/v1
 kind: WebhookAdmissionConfiguration
 kubeConfigFile: "<path-to-kubeconfig-file>"
- name: MutatingAdmissionWebhook
 configuration:
 apiVersion: apiserver.config.k8s.io/v1
 kind: WebhookAdmissionConfiguration
 kubeConfigFile: "<path-to-kubeconfig-file>"
```

```
Deprecated in v1.17 in favor of apiserver.config.k8s.io/v1
apiVersion: apiserver.k8s.io/v1alpha1
kind: AdmissionConfiguration
plugins:
- name: ValidatingAdmissionWebhook
 configuration:
 # Deprecated in v1.17 in favor of apiserver.config.k8s.io/v1,
kind=WebhookAdmissionConfiguration
 apiVersion: apiserver.config.k8s.io/v1alpha1
 kind: WebhookAdmission
 kubeConfigFile: "<path-to-kubeconfig-file>"
- name: MutatingAdmissionWebhook
 configuration:
 # Deprecated in v1.17 in favor of apiserver.config.k8s.io/v1,
kind=WebhookAdmissionConfiguration
```

```
apiVersion: apiserver.config.k8s.io/v1alpha1
kind: WebhookAdmission
kubeConfigFile: "<path-to-kubeconfig-file>"
```

For more information about AdmissionConfiguration, see the [AdmissionConfiguration \(v1\) reference](#). See the [webhook configuration](#) section for details about each config field.

In the kubeConfig file, provide the credentials:

```
apiVersion: v1
kind: Config
users:
name should be set to the DNS name of the service or the host (including port) of the URL the
webhook is configured to speak to.
If a non-443 port is used for services, it must be included in the name when configuring 1.16+
API servers.
#
For a webhook configured to speak to a service on the default port (443), specify the DNS
name of the service:
- name: webhook1.ns1.svc
user: ...
#
For a webhook configured to speak to a service on non-default port (e.g. 8443), specify the
DNS name and port of the service in 1.16+:
- name: webhook1.ns1.svc:8443
user: ...
and optionally create a second stanza using only the DNS name of the service for
compatibility with 1.15 API servers:
- name: webhook1.ns1.svc
user: ...
#
For webhooks configured to speak to a URL, match the host (and port) specified in the
webhook's URL. Examples:
A webhook with `url: https://www.example.com`:
- name: www.example.com
user: ...
#
A webhook with `url: https://www.example.com:443`:
- name: www.example.com:443
user: ...
#
A webhook with `url: https://www.example.com:8443`:
- name: www.example.com:8443
user: ...
#
- name: 'webhook1.ns1.svc'
 user:
 client-certificate-data: "<pem encoded certificate>"
 client-key-data: "<pem encoded key>"
The `name` supports using * to wildcard-match prefixing segments.
- name: '*.webhook-company.org'
 user:
 password: "<password>"
```

```
username: "<name>"
'*' is the default match.
- name: '*'
user:
 token: "<token>"
```

Of course you need to set up the webhook server to handle these authentication requests.

## Webhook request and response

### Request

Webhooks are sent as POST requests, with Content-Type: application/json, with an AdmissionReview API object in the admission.k8s.io API group serialized to JSON as the body.

Webhooks can specify what versions of AdmissionReview objects they accept with the admissionReviewVersions field in their configuration:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 admissionReviewVersions: ["v1", "v1beta1"]
```

admissionReviewVersions is a required field when creating webhook configurations. Webhooks are required to support at least one AdmissionReview version understood by the current and previous API server.

API servers send the first AdmissionReview version in the admissionReviewVersions list they support. If none of the versions in the list are supported by the API server, the configuration will not be allowed to be created. If an API server encounters a webhook configuration that was previously created and does not support any of the AdmissionReview versions the API server knows how to send, attempts to call to the webhook will fail and be subject to the [failure policy](#).

This example shows the data contained in an AdmissionReview object for a request to update the scale subresource of an apps/v1 Deployment:

```
apiVersion: admission.k8s.io/v1
kind: AdmissionReview
request:
 # Random uid uniquely identifying this admission call
 uid: 705ab4f5-6393-11e8-b7cc-42010a800002

 # Fully-qualified group/version/kind of the incoming object
 kind:
 group: autoscaling
 version: v1
 kind: Scale

 # Fully-qualified group/version/kind of the resource being modified
 resource:
 group: apps
 version: v1
```

```
resource: deployments

subresource, if the request is to a subresource
subResource: scale

Fully-qualified group/version/kind of the incoming object in the original request to the API
server.
This only differs from `kind` if the webhook specified `matchPolicy: Equivalent` and the
original request to the API server was converted to a version the webhook registered for.
requestKind:
 group: autoscaling
 version: v1
 kind: Scale

Fully-qualified group/version/kind of the resource being modified in the original request to
the API server.
This only differs from `resource` if the webhook specified `matchPolicy: Equivalent` and the
original request to the API server was converted to a version the webhook registered for.
requestResource:
 group: apps
 version: v1
 resource: deployments

subresource, if the request is to a subresource

This only differs from `subResource` if the webhook specified `matchPolicy: Equivalent` and
the
original request to the API server was converted to a version the webhook registered for.
requestSubResource: scale

Name of the resource being modified
name: my-deployment

Namespace of the resource being modified, if the resource is namespaced (or is a Namespace
object)
namespace: my-namespace

operation can be CREATE, UPDATE, DELETE, or CONNECT
operation: UPDATE

userInfo:
 # Username of the authenticated user making the request to the API server
 username: admin

 # UID of the authenticated user making the request to the API server
 uid: 014fbff9a07c

 # Group memberships of the authenticated user making the request to the API server
 groups:
 - system:authenticated
 - my-admin-group
 # Arbitrary extra info associated with the user making the request to the API server.
 # This is populated by the API server authentication layer and should be included
```

```

if any SubjectAccessReview checks are performed by the webhook.
extra:
 some-key:
 - some-value1
 - some-value2

object is the new object being admitted.
It is null for DELETE operations.
object:
 apiVersion: autoscaling/v1
 kind: Scale

oldObject is the existing object.
It is null for CREATE and CONNECT operations.
oldObject:
 apiVersion: autoscaling/v1
 kind: Scale

options contains the options for the operation being admitted, like meta.k8s.io/v1
CreateOptions, UpdateOptions, or DeleteOptions.
It is null for CONNECT operations.
options:
 apiVersion: meta.k8s.io/v1
 kind: UpdateOptions

dryRun indicates the API request is running in dry run mode and will not be persisted.
Webhooks with side effects should avoid actuating those side effects when dryRun is true.
See http://k8s.io/docs/reference/using-api/api-concepts/#make-a-dry-run-request for more
details.
dryRun: False

```

## Response

Webhooks respond with a 200 HTTP status code, Content-Type: application/json, and a body containing an AdmissionReview object (in the same version they were sent), with the response stanza populated, serialized to JSON.

At a minimum, the response stanza must contain the following fields:

- uid, copied from the request.uid sent to the webhook
- allowed, either set to true or false

Example of a minimal response from a webhook to allow a request:

```

{
 "apiVersion": "admission.k8s.io/v1",
 "kind": "AdmissionReview",
 "response": {
 "uid": "<value from request.uid>",
 "allowed": true
 }
}

```

Example of a minimal response from a webhook to forbid a request:

```
{
 "apiVersion": "admission.k8s.io/v1",
 "kind": "AdmissionReview",
 "response": {
 "uid": "<value from request.uid>",
 "allowed": false
 }
}
```

When rejecting a request, the webhook can customize the http code and message returned to the user using the status field. The specified status object is returned to the user. See the [API documentation](#) for details about the status type. Example of a response to forbid a request, customizing the HTTP status code and message presented to the user:

```
{
 "apiVersion": "admission.k8s.io/v1",
 "kind": "AdmissionReview",
 "response": {
 "uid": "<value from request.uid>",
 "allowed": false,
 "status": {
 "code": 403,
 "message": "You cannot do this because it is Tuesday and your name starts with A"
 }
 }
}
```

When allowing a request, a mutating admission webhook may optionally modify the incoming object as well. This is done using the patch and patchType fields in the response. The only currently supported patchType is JSONPatch. See [JSON patch](#) documentation for more details. For patchType: JSONPatch, the patch field contains a base64-encoded array of JSON patch operations.

As an example, a single patch operation that would set spec.replicas would be [{"op": "add", "path": "/spec/replicas", "value": 3}]

Base64-encoded, this would be

W3sib3AiOiAiYWRkIiwgInBhdGgiOiAiL3NwZWVvcmljYXMiLCBldmFsdWUiOiAiAzfV0=

So a webhook response to add that label would be:

```
{
 "apiVersion": "admission.k8s.io/v1",
 "kind": "AdmissionReview",
 "response": {
 "uid": "<value from request.uid>",
 "allowed": true,
 "patchType": "JSONPatch",
 "patch": "W3sib3AiOiAiYWRkIiwgInBhdGgiOiAiL3NwZWVvcmljYXMiLCBldmFsdWUiOiAiAzfV0="
 }
}
```

Admission webhooks can optionally return warning messages that are returned to the requesting client in HTTP Warning headers with a warning code of 299. Warnings can be sent with allowed or rejected admission responses.

If you're implementing a webhook that returns a warning:

- Don't include a "Warning:" prefix in the message
- Use warning messages to describe problems the client making the API request should correct or be aware of
- Limit warnings to 120 characters if possible

### Caution:

Individual warning messages over 256 characters may be truncated by the API server before being returned to clients. If more than 4096 characters of warning messages are added (from all sources), additional warning messages are ignored.

```
{
 "apiVersion": "admission.k8s.io/v1",
 "kind": "AdmissionReview",
 "response": {
 "uid": "<value from request.uid>",
 "allowed": true,
 "warnings": [
 "duplicate envvar entries specified with name MY_ENV",
 "memory request less than 4MB specified for container mycontainer, which will not start successfully"
]
 }
}
```

## Webhook configuration

To register admission webhooks, create `MutatingWebhookConfiguration` or `ValidatingWebhookConfiguration` API objects. The name of a `MutatingWebhookConfiguration` or a `ValidatingWebhookConfiguration` object must be a valid [DNS subdomain name](#).

Each configuration can contain one or more webhooks. If multiple webhooks are specified in a single configuration, each must be given a unique name. This is required in order to make resulting audit logs and metrics easier to match up to active configurations.

Each webhook defines the following things.

### Matching requests: rules

Each webhook must specify a list of rules used to determine if a request to the API server should be sent to the webhook. Each rule specifies one or more operations, apiGroups, apiVersions, and resources, and a resource scope:

- operations lists one or more operations to match. Can be "CREATE", "UPDATE", "DELETE", "CONNECT", or "\*" to match all.

- `apiGroups` lists one or more API groups to match. `""` is the core API group. `""` matches all API groups.
- `apiVersions` lists one or more API versions to match. `""` matches all API versions.
- `resources` lists one or more resources to match.
  - `""` matches all resources, but not subresources.
  - `"/"` matches all resources and subresources.
  - `"pods/"` matches all subresources of pods.
  - `"/status"` matches all status subresources.
- `scope` specifies a scope to match. Valid values are `"Cluster"`, `"Namespaced"`, and `""`. Subresources match the scope of their parent resource. Default is `""`.
  - `"Cluster"` means that only cluster-scoped resources will match this rule (Namespace API objects are cluster-scoped).
  - `"Namespaced"` means that only namespaced resources will match this rule.
  - `""` means that there are no scope restrictions.

If an incoming request matches one of the specified operations, groups, versions, resources, and scope for any of a webhook's rules, the request is sent to the webhook.

Here are other examples of rules that could be used to specify which resources should be intercepted.

Match CREATE or UPDATE requests to `apps/v1` and `apps/v1beta1` deployments and replicaset:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
...
webhooks:
- name: my-webhook.example.com
 rules:
 - operations: ["CREATE", "UPDATE"]
 apiGroups: ["apps"]
 apiVersions: ["v1", "v1beta1"]
 resources: ["deployments", "replicasets"]
 scope: "Namespaced"
...
```

Match create requests for all resources (but not subresources) in all API groups and versions:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 rules:
 - operations: ["CREATE"]
 apiGroups: [""]
 apiVersions: [""]
 resources: [""]
 scope: ""
```

Match update requests for all status subresources in all API groups and versions:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 rules:
 - operations: ["UPDATE"]
 apiGroups: ["*"]
 apiVersions: ["*"]
 resources: ["*/status"]
 scope: "*"

```

## Matching requests: objectSelector

Webhooks may optionally limit which requests are intercepted based on the labels of the objects they would be sent, by specifying an `objectSelector`. If specified, the `objectSelector` is evaluated against both the object and `oldObject` that would be sent to the webhook, and is considered to match if either object matches the selector.

A null object (`oldObject` in the case of create, or `newObject` in the case of delete), or an object that cannot have labels (like a `DeploymentRollback` or a `PodProxyOptions` object) is not considered to match.

Use the object selector only if the webhook is opt-in, because end users may skip the admission webhook by setting the labels.

This example shows a mutating webhook that would match a CREATE of any resource (but not subresources) with the label `foo: bar`:

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 objectSelector:
 matchLabels:
 foo: bar
 rules:
 - operations: ["CREATE"]
 apiGroups: ["*"]
 apiVersions: ["*"]
 resources: ["*"]
 scope: "*"

```

See [labels concept](#) for more examples of label selectors.

## Matching requests: namespaceSelector

Webhooks may optionally limit which requests for namespaced resources are intercepted, based on the labels of the containing namespace, by specifying a `namespaceSelector`.

The `namespaceSelector` decides whether to run the webhook on a request for a namespaced resource (or a `Namespace` object), based on whether the namespace's labels match the selector.

If the object itself is a namespace, the matching is performed on `object.metadata.labels`. If the object is a cluster scoped resource other than a Namespace, `namespaceSelector` has no effect.

This example shows a mutating webhook that matches a CREATE of any namespaced resource inside a namespace that does not have a "runlevel" label of "0" or "1":

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 namespaceSelector:
 matchExpressions:
 - key: runlevel
 operator: NotIn
 values: ["0", "1"]
 rules:
 - operations: ["CREATE"]
 apiGroups: ["*"]
 apiVersions: ["*"]
 resources: ["*"]
 scope: "Namespaced"
```

This example shows a validating webhook that matches a CREATE of any namespaced resource inside a namespace that is associated with the "environment" of "prod" or "staging":

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 namespaceSelector:
 matchExpressions:
 - key: environment
 operator: In
 values: ["prod", "staging"]
 rules:
 - operations: ["CREATE"]
 apiGroups: ["*"]
 apiVersions: ["*"]
 resources: ["*"]
 scope: "Namespaced"
```

See [labels concept](#) for more examples of label selectors.

## Matching requests: matchPolicy

API servers can make objects available via multiple API groups or versions.

For example, if a webhook only specified a rule for some API groups/versions (like `apiGroups: ["apps"]`, `apiVersions: ["v1", "v1beta1"]`), and a request was made to modify the resource via another API group/version (like `extensions/v1beta1`), the request would not be sent to the webhook.

The `matchPolicy` lets a webhook define how its rules are used to match incoming requests. Allowed values are `Exact` or `Equivalent`.

- `Exact` means a request should be intercepted only if it exactly matches a specified rule.
- `Equivalent` means a request should be intercepted if modifies a resource listed in rules, even via another API group or version.

In the example given above, the webhook that only registered for `apps/v1` could use `matchPolicy`:

- `matchPolicy: Exact` would mean the `extensions/v1beta1` request would not be sent to the webhook
- `matchPolicy: Equivalent` means the `extensions/v1beta1` request would be sent to the webhook (with the objects converted to a version the webhook had specified: `apps/v1`)

Specifying `Equivalent` is recommended, and ensures that webhooks continue to intercept the resources they expect when upgrades enable new versions of the resource in the API server.

When a resource stops being served by the API server, it is no longer considered equivalent to other versions of that resource that are still served. For example, `extensions/v1beta1` deployments were first deprecated and then removed (in Kubernetes v1.16).

Since that removal, a webhook with a `apiGroups:["extensions"]`, `apiVersions:["v1beta1"]`, `resources:["deployments"]` rule does not intercept deployments created via `apps/v1` APIs. For that reason, webhooks should prefer registering for stable versions of resources.

This example shows a validating webhook that intercepts modifications to deployments (no matter the API group or version), and is always sent an `apps/v1` Deployment object:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 matchPolicy: Equivalent
 rules:
 - operations: ["CREATE","UPDATE","DELETE"]
 apiGroups: ["apps"]
 apiVersions: ["v1"]
 resources: ["deployments"]
 scope: "Namespaced"
```

The `matchPolicy` for an admission webhooks defaults to `Equivalent`.

## Matching requests: `matchConditions`

FEATURE STATE: Kubernetes v1.30 [stable]

You can define *match conditions* for webhooks if you need fine-grained request filtering. These conditions are useful if you find that match rules, objectSelectors and namespaceSelectors still doesn't provide the filtering you want over when to call out over HTTP. Match conditions are [CEL expressions](#). All match conditions must evaluate to true for the webhook to be called.

Here is an example illustrating a few different uses for match conditions:

```

apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 matchPolicy: Equivalent
 rules:
 - operations: ['CREATE','UPDATE']
 apiGroups: ['*']
 apiVersions: ['*']
 resources: ['*']
 failurePolicy: 'Ignore' # Fail-open (optional)
 sideEffects: None
 clientConfig:
 service:
 namespace: my-namespace
 name: my-webhook
 caBundle: '<omitted>'
 # You can have up to 64 matchConditions per webhook
 matchConditions:
 - name: 'exclude-leases' # Each match condition must have a unique name
 expression: '!(request.resource.group == "coordination.k8s.io" &&
request.resource.resource == "leases")' # Match non-lease resources.
 - name: 'exclude-kubelet-requests'
 expression: '!("system:nodes" in request.userInfo.groups)' # Match requests made by non-
node users.
 - name: 'rbac' # Skip RBAC requests, which are handled by the second webhook.
 expression: 'request.resource.group != "rbac.authorization.k8s.io"'

 # This example illustrates the use of the 'authorizer'. The authorization check is more
expensive
 # than a simple expression, so in this example it is scoped to only RBAC requests by using a
second
webhook. Both webhooks can be served by the same endpoint.
- name: rbac.my-webhook.example.com
 matchPolicy: Equivalent
 rules:
 - operations: ['CREATE','UPDATE']
 apiGroups: ['rbac.authorization.k8s.io']
 apiVersions: ['*']
 resources: ['*']
 failurePolicy: 'Fail' # Fail-closed (the default)
 sideEffects: None
 clientConfig:
 service:
 namespace: my-namespace
 name: my-webhook
 caBundle: '<omitted>'
 # You can have up to 64 matchConditions per webhook
 matchConditions:
 - name: 'breakglass'
 # Skip requests made by users authorized to 'breakglass' on this webhook.
 # The 'breakglass' API verb does not need to exist outside this check.
 expression: '!'

```

```
authorizer.group("admissionregistration.k8s.io").resource("validatingwebhookconfigurations").name("my-webhook.example.com").check("breakglass").allowed()'
```

### Note:

You can define up to 64 elements in the `matchConditions` field per webhook.

Match conditions have access to the following CEL variables:

- `object` - The object from the incoming request. The value is null for DELETE requests. The object version may be converted based on the [matchPolicy](#).
- `oldObject` - The existing object. The value is null for CREATE requests.
- `request` - The request portion of the [AdmissionReview](#), excluding `object` and `oldObject`.
- `authorizer` - A CEL Authorizer. May be used to perform authorization checks for the principal (authenticated user) of the request. See [Authz](#) in the Kubernetes CEL library documentation for more details.
- `authorizer.requestResource` - A shortcut for an authorization check configured with the request resource (group, resource, (subresource), namespace, name).

For more information on CEL expressions, refer to the [Common Expression Language in Kubernetes reference](#).

In the event of an error evaluating a match condition the webhook is never called. Whether to reject the request is determined as follows:

1. If **any** match condition evaluated to false (regardless of other errors), the API server skips the webhook.
2. Otherwise:
  - for [failurePolicy: Fail](#), reject the request (without calling the webhook).
  - for [failurePolicy: Ignore](#), proceed with the request but skip the webhook.

## Contacting the webhook

Once the API server has determined a request should be sent to a webhook, it needs to know how to contact the webhook. This is specified in the `clientConfig` stanza of the webhook configuration.

Webhooks can either be called via a URL or a service reference, and can optionally include a custom CA bundle to use to verify the TLS connection.

### URL

`url` gives the location of the webhook, in standard URL form (`scheme://host:port/path`).

The host should not refer to a service running in the cluster; use a service reference by specifying the `service` field instead. The host might be resolved via external DNS in some API servers (e.g., kube-apiserver cannot resolve in-cluster DNS as that would be a layering violation). host may also be an IP address.

Please note that using `localhost` or `127.0.0.1` as a host is risky unless you take great care to run this webhook on all hosts which run an API server which might need to make calls to this webhook. Such installations are likely to be non-portable or not readily run in a new cluster.

The scheme must be "https"; the URL must begin with "https://".

Attempting to use a user or basic auth (for example user:password@) is not allowed. Fragments (#...) and query parameters (?...) are also not allowed.

Here is an example of a mutating webhook configured to call a URL (and expects the TLS certificate to be verified using system trust roots, so does not specify a caBundle):

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 clientConfig:
 url: "https://my-webhook.example.com:9443/my-webhook-path"
```

## Service reference

The service stanza inside clientConfig is a reference to the service for this webhook. If the webhook is running within the cluster, then you should use service instead of url. The service namespace and name are required. The port is optional and defaults to 443. The path is optional and defaults to "/".

Here is an example of a mutating webhook configured to call a service on port "1234" at the subpath "/my-path", and to verify the TLS connection against the ServerName my-service-name.my-service-namespace.svc using a custom CA bundle:

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 clientConfig:
 caBundle: <CA_BUNDLE>
 service:
 namespace: my-service-namespace
 name: my-service-name
 path: /my-path
 port: 1234
```

## Note:

You must replace the <CA\_BUNDLE> in the above example by a valid CA bundle which is a PEM-encoded CA bundle for validating the webhook's server certificate.

## Side effects

Webhooks typically operate only on the content of the AdmissionReview sent to them. Some webhooks, however, make out-of-band changes as part of processing admission requests.

Webhooks that make out-of-band changes ("side effects") must also have a reconciliation mechanism (like a controller) that periodically determines the actual state of the world, and adjusts the out-of-band data modified by the admission webhook to reflect reality. This is because a call to an admission webhook does not guarantee the admitted object will be

persisted as is, or at all. Later webhooks can modify the content of the object, a conflict could be encountered while writing to storage, or the server could power off before persisting the object.

Additionally, webhooks with side effects must skip those side-effects when `dryRun: true` admission requests are handled. A webhook must explicitly indicate that it will not have side-effects when run with `dryRun`, or the dry-run request will not be sent to the webhook and the API request will fail instead.

Webhooks indicate whether they have side effects using the `sideEffects` field in the webhook configuration:

- `None`: calling the webhook will have no side effects.
- `NoneOnDryRun`: calling the webhook will possibly have side effects, but if a request with `dryRun: true` is sent to the webhook, the webhook will suppress the side effects (the webhook is `dryRun`-aware).

Here is an example of a validating webhook indicating it has no side effects on `dryRun: true` requests:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 sideEffects: NoneOnDryRun
```

## Timeouts

Because webhooks add to API request latency, they should evaluate as quickly as possible. `timeoutSeconds` allows configuring how long the API server should wait for a webhook to respond before treating the call as a failure.

If the timeout expires before the webhook responds, the webhook call will be ignored or the API call will be rejected based on the [failure policy](#).

The timeout value must be between 1 and 30 seconds.

Here is an example of a validating webhook with a custom timeout of 2 seconds:

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 timeoutSeconds: 2
```

The timeout for an admission webhook defaults to 10 seconds.

## Reinvocation policy

A single ordering of mutating admissions plugins (including webhooks) does not work for all cases (see <https://issue.k8s.io/64333> as an example). A mutating webhook can add a new sub-structure to the object (like adding a container to a pod), and other mutating plugins which have already run may have opinions on those new structures (like setting an `imagePullPolicy` on all containers).

To allow mutating admission plugins to observe changes made by other plugins, built-in mutating admission plugins are re-run if a mutating webhook modifies an object, and mutating webhooks can specify a `reinvocationPolicy` to control whether they are reinvoked as well.

`reinvocationPolicy` may be set to `Never` or `IfNeeded`. It defaults to `Never`.

- `Never`: the webhook must not be called more than once in a single admission evaluation.
- `IfNeeded`: the webhook may be called again as part of the admission evaluation if the object being admitted is modified by other admission plugins after the initial webhook call.

The important elements to note are:

- The number of additional invocations is not guaranteed to be exactly one.
- If additional invocations result in further modifications to the object, webhooks are not guaranteed to be invoked again.
- Webhooks that use this option may be reordered to minimize the number of additional invocations.
- To validate an object after all mutations are guaranteed complete, use a validating admission webhook instead (recommended for webhooks with side-effects).

Here is an example of a mutating webhook opting into being re-invoked if later admission plugins modify the object:

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 reinvocationPolicy: IfNeeded
```

Mutating webhooks must be [idempotent](#), able to successfully process an object they have already admitted and potentially modified. This is true for all mutating admission webhooks, since any change they can make in an object could already exist in the user-provided object, but it is essential for webhooks that opt into reinvocation.

## Failure policy

`failurePolicy` defines how unrecognized errors and timeout errors from the admission webhook are handled. Allowed values are `Ignore` or `Fail`.

- `Ignore` means that an error calling the webhook is ignored and the API request is allowed to continue.
- `Fail` means that an error calling the webhook causes the admission to fail and the API request to be rejected.

Here is a mutating webhook configured to reject an API request if errors are encountered calling the admission webhook:

```
apiVersion: admissionregistration.k8s.io/v1
kind: MutatingWebhookConfiguration
webhooks:
- name: my-webhook.example.com
 failurePolicy: Fail
```

The default failurePolicy for an admission webhooks is Fail.

## Monitoring admission webhooks

The API server provides ways to monitor admission webhook behaviors. These monitoring mechanisms help cluster admins to answer questions like:

1. Which mutating webhook mutated the object in a API request?
2. What change did the mutating webhook applied to the object?
3. Which webhooks are frequently rejecting API requests? What's the reason for a rejection?

## Mutating webhook auditing annotations

Sometimes it's useful to know which mutating webhook mutated the object in a API request, and what change did the webhook apply.

The Kubernetes API server performs [auditing](#) on each mutating webhook invocation. Each invocation generates an auditing annotation capturing if a request object is mutated by the invocation, and optionally generates an annotation capturing the applied patch from the webhook admission response. The annotations are set in the audit event for given request on given stage of its execution, which is then pre-processed according to a certain policy and written to a backend.

The audit level of a event determines which annotations get recorded:

- At Metadata audit level or higher, an annotation with key `mutation.webhook.admission.k8s.io/round_{round idx}_index_{order idx}` gets logged with JSON payload indicating a webhook gets invoked for given request and whether it mutated the object or not.

For example, the following annotation gets recorded for a webhook being reinvoked. The webhook is ordered the third in the mutating webhook chain, and didn't mutated the request object during the invocation.

```
the audit event recorded
{
 "kind": "Event",
 "apiVersion": "audit.k8s.io/v1",
 "annotations": {
 "mutation.webhook.admission.k8s.io/round_1_index_2": "{\"configuration\":\"my-mutating-webhook-configuration.example.com\",\"webhook\":\"my-webhook.example.com\",\"mutated\": false}"
 # other annotations
 ...
 }
 # other fields
 ...
}
```

```
the annotation value deserialized
{
 "configuration": "my-mutating-webhook-configuration.example.com",
 "webhook": "my-webhook.example.com",
 "mutated": false
}
```

The following annotation gets recorded for a webhook being invoked in the first round. The webhook is ordered the first in the mutating webhook chain, and mutated the request object during the invocation.

```
the audit event recorded
{
 "kind": "Event",
 "apiVersion": "audit.k8s.io/v1",
 "annotations": {
 "mutation.webhook.admission.k8s.io/round_0_index_0": "{\"configuration\":\"my-mutating-webhook-configuration.example.com\",\"webhook\":\"my-webhook-always-mutate.example.com\",\"mutated\": true}"
 # other annotations
 ...
 }
 # other fields
 ...
}
```

```
the annotation value deserialized
{
 "configuration": "my-mutating-webhook-configuration.example.com",
 "webhook": "my-webhook-always-mutate.example.com",
 "mutated": true
}
```

- At Request audit level or higher, an annotation with key `patch.webhook.admission.k8s.io/round_{round idx}_index_{order idx}` gets logged with JSON payload indicating a webhook gets invoked for given request and what patch gets applied to the request object.

For example, the following annotation gets recorded for a webhook being reinvoked. The webhook is ordered the fourth in the mutating webhook chain, and responded with a JSON patch which got applied to the request object.

```
the audit event recorded
{
 "kind": "Event",
 "apiVersion": "audit.k8s.io/v1",
 "annotations": {
 "patch.webhook.admission.k8s.io/round_1_index_3": "{\"configuration\":\"my-other-mutating-webhook-configuration.example.com\",\"webhook\":\"my-webhook-always-mutate.example.com\",\"patch\":{\"op\":\"add\",\"path\":\"/data/mutation-stage\",\"value\":\"yes\"}},\"patchType\":\"JSONPatch\"}"
 # other annotations
 ...
 }
}
```

```

other fields
...
}

the annotation value deserialized
{
 "configuration": "my-other-mutating-webhook-configuration.example.com",
 "webhook": "my-webhook-always-mutate.example.com",
 "patchType": "JSONPatch",
 "patch": [
 {
 "op": "add",
 "path": "/data/mutation-stage",
 "value": "yes"
 }
]
}

```

## Admission webhook metrics

The API server exposes Prometheus metrics from the `/metrics` endpoint, which can be used for monitoring and diagnosing API server status. The following metrics record status related to admission webhooks.

### API server admission webhook rejection count

Sometimes it's useful to know which admission webhooks are frequently rejecting API requests, and the reason for a rejection.

The API server exposes a Prometheus counter metric recording admission webhook rejections. The metrics are labelled to identify the causes of webhook rejection(s):

- `name`: the name of the webhook that rejected a request.
- `operation`: the operation type of the request, can be one of CREATE, UPDATE, DELETE and CONNECT.
- `type`: the admission webhook type, can be one of admit and validating.
- `error_type`: identifies if an error occurred during the webhook invocation that caused the rejection. Its value can be one of:
  - `calling_webhook_error`: unrecognized errors or timeout errors from the admission webhook happened and the webhook's [Failure policy](#) is set to Fail.
  - `no_error`: no error occurred. The webhook rejected the request with `allowed: false` in the admission response. The metrics label `rejection_code` records the `.status.code` set in the admission response.
  - `apiserver_internal_error`: an API server internal error happened.
- `rejection_code`: the HTTP status code set in the admission response when a webhook rejected a request.

Example of the rejection count metrics:

```
HELP apiserver_admission_webhook_rejection_count [ALPHA] Admission webhook
rejection count, identified by name and broken out for each admission type (validating or
admit) and operation. Additional labels specify an error type (calling_webhook_error or
apiserver_internal_error if an error occurred; no_error otherwise) and optionally a non-zero
rejection code if the webhook rejects the request with an HTTP status code (honored by the
apiserver when the code is greater or equal to 400). Codes greater than 600 are truncated to 600,
to keep the metrics cardinality bounded.
TYPE apiserver_admission_webhook_rejection_count counter
apiserver_admission_webhook_rejection_count{error_type="calling_webhook_error",name="always-timeout-
webhook.example.com",operation="CREATE",rejection_code="0",type="validating"} 1
apiserver_admission_webhook_rejection_count{error_type="calling_webhook_error",name="in
valid-admission-response-
webhook.example.com",operation="CREATE",rejection_code="0",type="validating"} 1
apiserver_admission_webhook_rejection_count{error_type="no_error",name="deny-unwanted-
configmap-data.example.com",operation="CREATE",rejection_code="400",type="validating"} 13
```

## Best practices and warnings

### Idempotence

An idempotent mutating admission webhook is able to successfully process an object it has already admitted and potentially modified. The admission can be applied multiple times without changing the result beyond the initial application.

#### Example of idempotent mutating admission webhooks:

1. For a CREATE pod request, set the field `.spec.securityContext.runAsNonRoot` of the pod to true, to enforce security best practices.
2. For a CREATE pod request, if the field `.spec.containers[].resources.limits` of a container is not set, set default resource limits.
3. For a CREATE pod request, inject a sidecar container with name `foo-sidecar` if no container with the name `foo-sidecar` already exists.

In the cases above, the webhook can be safely reinvoked, or admit an object that already has the fields set.

#### Example of non-idempotent mutating admission webhooks:

1. For a CREATE pod request, inject a sidecar container with name `foo-sidecar` suffixed with the current timestamp (e.g. `foo-sidecar-19700101-000000`).
2. For a CREATE/UPDATE pod request, reject if the pod has label `"env"` set, otherwise add an `"env": "prod"` label to the pod.
3. For a CREATE pod request, blindly append a sidecar container named `foo-sidecar` without looking to see if there is already a `foo-sidecar` container in the pod.

In the first case above, reinvoking the webhook can result in the same sidecar being injected multiple times to a pod, each time with a different container name. Similarly the webhook can inject duplicated containers if the sidecar already exists in a user-provided pod.

In the second case above, reinvoking the webhook will result in the webhook failing on its own output.

In the third case above, reinvoking the webhook will result in duplicated containers in the pod spec, which makes the request invalid and rejected by the API server.

## **Intercepting all versions of an object**

It is recommended that admission webhooks should always intercept all versions of an object by setting `.webhooks[].matchPolicy` to `Equivalent`. It is also recommended that admission webhooks should prefer registering for stable versions of resources. Failure to intercept all versions of an object can result in admission policies not being enforced for requests in certain versions. See [Matching requests: matchPolicy](#) for examples.

## **Availability**

It is recommended that admission webhooks should evaluate as quickly as possible (typically in milliseconds), since they add to API request latency. It is encouraged to use a small timeout for webhooks. See [Timeouts](#) for more detail.

It is recommended that admission webhooks should leverage some format of load-balancing, to provide high availability and performance benefits. If a webhook is running within the cluster, you can run multiple webhook backends behind a service to leverage the load-balancing that service supports.

## **Guaranteeing the final state of the object is seen**

Admission webhooks that need to guarantee they see the final state of the object in order to enforce policy should use a validating admission webhook, since objects can be modified after being seen by mutating webhooks.

For example, a mutating admission webhook is configured to inject a sidecar container with name "foo-sidecar" on every CREATE pod request. If the sidecar *must* be present, a validating admission webhook should also be configured to intercept CREATE pod requests, and validate that a container with name "foo-sidecar" with the expected configuration exists in the to-be-created object.

## **Avoiding deadlocks in self-hosted webhooks**

A webhook running inside the cluster might cause deadlocks for its own deployment if it is configured to intercept resources required to start its own pods.

For example, a mutating admission webhook is configured to admit CREATE pod requests only if a certain label is set in the pod (e.g. "env": "prod"). The webhook server runs in a deployment which doesn't set the "env" label. When a node that runs the webhook server pods becomes unhealthy, the webhook deployment will try to reschedule the pods to another node. However the requests will get rejected by the existing webhook server since the "env" label is unset, and the migration cannot happen.

It is recommended to exclude the namespace where your webhook is running with a [namespaceSelector](#).

## Side effects

It is recommended that admission webhooks should avoid side effects if possible, which means the webhooks operate only on the content of the AdmissionReview sent to them, and do not make out-of-band changes. The `.webhooks[].sideEffects` field should be set to `None` if a webhook doesn't have any side effect.

If side effects are required during the admission evaluation, they must be suppressed when processing an AdmissionReview object with `dryRun` set to `true`, and the `.webhooks[].sideEffects` field should be set to `NoneOnDryRun`. See [Side effects](#) for more detail.

## Avoiding operating on the kube-system namespace

The `kube-system` namespace contains objects created by the Kubernetes system, e.g. service accounts for the control plane components, pods like `kube-dns`. Accidentally mutating or rejecting requests in the `kube-system` namespace may cause the control plane components to stop functioning or introduce unknown behavior. If your admission webhooks don't intend to modify the behavior of the Kubernetes control plane, exclude the `kube-system` namespace from being intercepted using a [namespaceSelector](#).

# Managing Service Accounts

A *ServiceAccount* provides an identity for processes that run in a Pod.

A process inside a Pod can use the identity of its associated service account to authenticate to the cluster's API server.

For an introduction to service accounts, read [configure service accounts](#).

This task guide explains some of the concepts behind ServiceAccounts. The guide also explains how to obtain or revoke tokens that represent ServiceAccounts.

## Before you begin

You need to have a Kubernetes cluster, and the `kubectl` command-line tool must be configured to communicate with your cluster. It is recommended to run this tutorial on a cluster with at least two nodes that are not acting as control plane hosts. If you do not already have a cluster, you can create one by using [minikube](#) or you can use one of these Kubernetes playgrounds:

- [Killercodea](#)
- [Play with Kubernetes](#)

To be able to follow these steps exactly, ensure you have a namespace named `examplens`. If you don't, create one by running:

```
kubectl create namespace examplens
```

# User accounts versus service accounts

Kubernetes distinguishes between the concept of a user account and a service account for a number of reasons:

- User accounts are for humans. Service accounts are for application processes, which (for Kubernetes) run in containers that are part of pods.
- User accounts are intended to be global: names must be unique across all namespaces of a cluster. No matter what namespace you look at, a particular username that represents a user represents the same user. In Kubernetes, service accounts are namespaced: two different namespaces can contain ServiceAccounts that have identical names.
- Typically, a cluster's user accounts might be synchronised from a corporate database, where new user account creation requires special privileges and is tied to complex business processes. By contrast, service account creation is intended to be more lightweight, allowing cluster users to create service accounts for specific tasks on demand. Separating ServiceAccount creation from the steps to onboard human users makes it easier for workloads to follow the principle of least privilege.
- Auditing considerations for humans and service accounts may differ; the separation makes that easier to achieve.
- A configuration bundle for a complex system may include definition of various service accounts for components of that system. Because service accounts can be created without many constraints and have namespaced names, such configuration is usually portable.

## Bound service account tokens

ServiceAccount tokens can be bound to API objects that exist in the kube-apiserver. This can be used to tie the validity of a token to the existence of another API object. Supported object types are as follows:

- Pod (used for projected volume mounts, see below)
- Secret (can be used to allow revoking a token by deleting the Secret)
- Node (in v1.30, creating new node-bound tokens is alpha, using existing node-bound tokens is beta)

When a token is bound to an object, the object's `metadata.name` and `metadata.uid` are stored as extra 'private claims' in the issued JWT.

When a bound token is presented to the kube-apiserver, the service account authenticator will extract and verify these claims. If the referenced object no longer exists (or its `metadata.uid` does not match), the request will not be authenticated.

## Additional metadata in Pod bound tokens

FEATURE STATE: Kubernetes v1.30 [beta]

When a service account token is bound to a Pod object, additional metadata is also embedded into the token that indicates the value of the bound pod's `spec.nodeName` field, and the uid of that Node, if available.

This node information is **not** verified by the kube-apiserver when the token is used for authentication. It is included so integrators do not have to fetch Pod or Node API objects to check the associated Node name and uid when inspecting a JWT.

## Verifying and inspecting private claims

The TokenReview API can be used to verify and extract private claims from a token:

1. First, assume you have a pod named test-pod and a service account named my-sa.
2. Create a token that is bound to this Pod:

```
kubectl create token my-sa --bound-object-kind="Pod" --bound-object-name="test-pod"
```

1. Copy this token into a new file named tokenreview.yaml:

```
apiVersion: authentication.k8s.io/v1
kind: TokenReview
spec:
 token: <token from step 2>
```

1. Submit this resource to the apiserver for review:

```
kubectl create -o yaml -f tokenreview.yaml # we use '-o yaml' so we can inspect the output
```

You should see an output like below:

```
apiVersion: authentication.k8s.io/v1
kind: TokenReview
metadata:
 creationTimestamp: null
spec:
 token: <token>
status:
 audiences:
 - https://kubernetes.default.svc.cluster.local
 authenticated: true
 user:
 extra:
 authentication.kubernetes.io/credential-id:
 - JTI=7ee52be0-9045-4653-aa5e-0da57b8dccdc
 authentication.kubernetes.io/node-name:
 - kind-control-plane
 authentication.kubernetes.io/node-uid:
 - 497e9d9a-47aa-4930-b0f6-9f2fb574c8c6
 authentication.kubernetes.io/pod-name:
 - test-pod
 authentication.kubernetes.io/pod-uid:
 - e87dbbd6-3d7e-45db-aafb-72b24627dff5
 groups:
 - system:serviceaccounts
 - system:serviceaccounts:default
 - system:authenticated
 uid: f8b4161b-2e2b-11e9-86b7-2afc33b31a7e
 username: system:serviceaccount:default:my-sa
```

## Note:

Despite using `kubectl create -f` to create this resource, and defining it similar to other resource types in Kubernetes, `TokenReview` is a special type and the `kube-apiserver` does not actually persist the `TokenReview` object into `etcd`. Hence `kubectl get tokenreview` is not a valid command.

## Bound service account token volume mechanism

FEATURE STATE: Kubernetes v1.22 [stable]

By default, the Kubernetes control plane (specifically, the [ServiceAccount admission controller](#)) adds a [projected volume](#) to Pods, and this volume includes a token for Kubernetes API access.

Here's an example of how that looks for a launched Pod:

```
...
- name: kube-api-access-<random-suffix>
 projected:
 sources:
 - serviceAccountToken:
 path: token # must match the path the app expects
 - configMap:
 items:
 - key: ca.crt
 path: ca.crt
 name: kube-root-ca.crt
 - downwardAPI:
 items:
 - fieldRef:
 apiVersion: v1
 fieldPath: metadata.namespace
 path: namespace
```

That manifest snippet defines a projected volume that consists of three sources. In this case, each source also represents a single path within that volume. The three sources are:

1. A `serviceAccountToken` source, that contains a token that the kubelet acquires from `kube-apiserver`. The kubelet fetches time-bound tokens using the `TokenRequest` API. A token served for a `TokenRequest` expires either when the pod is deleted or after a defined lifespan (by default, that is 1 hour). The kubelet also refreshes that token before the token expires. The token is bound to the specific Pod and has the `kube-apiserver` as its audience. This mechanism superseded an earlier mechanism that added a volume based on a `Secret`, where the `Secret` represented the `ServiceAccount` for the Pod, but did not expire.
2. A `configMap` source. The `ConfigMap` contains a bundle of certificate authority data. Pods can use these certificates to make sure that they are connecting to your cluster's `kube-apiserver` (and not to middlebox or an accidentally misconfigured peer).
3. A `downwardAPI` source that looks up the name of the namespace containing the Pod, and makes that name information available to application code running inside the Pod.

Any container within the Pod that mounts this particular volume can access the above information.

**Note:**

There is no specific mechanism to invalidate a token issued via `TokenRequest`. If you no longer trust a bound service account token for a Pod, you can delete that Pod. Deleting a Pod expires its bound service account tokens.

## Manual Secret management for ServiceAccounts

Versions of Kubernetes before v1.22 automatically created credentials for accessing the Kubernetes API. This older mechanism was based on creating token Secrets that could then be mounted into running Pods.

In more recent versions, including Kubernetes v1.30, API credentials are [obtained directly](#) using the [TokenRequest](#) API, and are mounted into Pods using a projected volume. The tokens obtained using this method have bounded lifetimes, and are automatically invalidated when the Pod they are mounted into is deleted.

You can still [manually create](#) a Secret to hold a service account token; for example, if you need a token that never expires.

Once you manually create a Secret and link it to a ServiceAccount, the Kubernetes control plane automatically populates the token into that Secret.

**Note:**

Although the manual mechanism for creating a long-lived ServiceAccount token exists, using [TokenRequest](#) to obtain short-lived API access tokens is recommended instead.

## Auto-generated legacy ServiceAccount token clean up

Before version 1.24, Kubernetes automatically generated Secret-based tokens for ServiceAccounts. To distinguish between automatically generated tokens and manually created ones, Kubernetes checks for a reference from the ServiceAccount's `secrets` field. If the Secret is referenced in the `secrets` field, it is considered an auto-generated legacy token. Otherwise, it is considered a manually created legacy token. For example:

```
apiVersion: v1
kind: ServiceAccount
metadata:
 name: build-robot
 namespace: default
secrets:
 - name: build-robot-secret # usually NOT present for a manually generated token
```

Beginning from version 1.29, legacy ServiceAccount tokens that were generated automatically will be marked as invalid if they remain unused for a certain period of time (set to default at one year). Tokens that continue to be unused for this defined period (again, by default, one year) will subsequently be purged by the control plane.

If users use an invalidated auto-generated token, the token validator will

1. add an audit annotation for the key-value pair `authentication.k8s.io/legacy-token-invalidated: <secret name>/<namespace>`,
2. increment the `invalid_legacy_auto_token_uses_total` metric count,
3. update the Secret label `kubernetes.io/legacy-token-last-used` with the new date,
4. return an error indicating that the token has been invalidated.

When receiving this validation error, users can update the Secret to remove the `kubernetes.io/legacy-token-invalid-since` label to temporarily allow use of this token.

Here's an example of an auto-generated legacy token that has been marked with the `kubernetes.io/legacy-token-last-used` and `kubernetes.io/legacy-token-invalid-since` labels:

```
apiVersion: v1
kind: Secret
metadata:
 name: build-robot-secret
 namespace: default
labels:
 kubernetes.io/legacy-token-last-used: 2022-10-24
 kubernetes.io/legacy-token-invalid-since: 2023-10-25
annotations:
 kubernetes.io/service-account.name: build-robot
type: kubernetes.io/service-account-token
```

## Control plane details

### ServiceAccount controller

A ServiceAccount controller manages the ServiceAccounts inside namespaces, and ensures a ServiceAccount named "default" exists in every active namespace.

### Token controller

The service account token controller runs as part of `kube-controller-manager`. This controller acts asynchronously. It:

- watches for ServiceAccount deletion and deletes all corresponding ServiceAccount token Secrets.
- watches for ServiceAccount token Secret addition, and ensures the referenced ServiceAccount exists, and adds a token to the Secret if needed.
- watches for Secret deletion and removes a reference from the corresponding ServiceAccount if needed.

You must pass a service account private key file to the token controller in the `kube-controller-manager` using the `--service-account-private-key-file` flag. The private key is used to sign generated service account tokens. Similarly, you must pass the corresponding public key to the `kube-apiserver` using the `--service-account-key-file` flag. The public key will be used to verify the tokens during authentication.

## ServiceAccount admission controller

The modification of pods is implemented via a plugin called an [Admission Controller](#). It is part of the API server. This admission controller acts synchronously to modify pods as they are created. When this plugin is active (and it is by default on most distributions), then it does the following when a Pod is created:

1. If the pod does not have a `.spec.serviceAccountName` set, the admission controller sets the name of the ServiceAccount for this incoming Pod to default.
2. The admission controller ensures that the ServiceAccount referenced by the incoming Pod exists. If there is no ServiceAccount with a matching name, the admission controller rejects the incoming Pod. That check applies even for the default ServiceAccount.
3. Provided that neither the ServiceAccount's `automountServiceAccountToken` field nor the Pod's `automountServiceAccountToken` field is set to false:
  - the admission controller mutates the incoming Pod, adding an extra [volume](#) that contains a token for API access.
  - the admission controller adds a `volumeMount` to each container in the Pod, skipping any containers that already have a volume mount defined for the path `/var/run/secrets/kubernetes.io/serviceaccount`. For Linux containers, that volume is mounted at `/var/run/secrets/kubernetes.io/serviceaccount`; on Windows nodes, the mount is at the equivalent path.
4. If the spec of the incoming Pod doesn't already contain any `imagePullSecrets`, then the admission controller adds `imagePullSecrets`, copying them from the ServiceAccount.

## Legacy ServiceAccount token tracking controller

FEATURE STATE: Kubernetes v1.28 [stable]

This controller generates a ConfigMap called `kube-system/kube-apiserver-legacy-service-account-token-tracking` in the `kube-system` namespace. The ConfigMap records the timestamp when legacy service account tokens began to be monitored by the system.

## Legacy ServiceAccount token cleaner

FEATURE STATE: Kubernetes v1.30 [stable]

The legacy ServiceAccount token cleaner runs as part of the `kube-controller-manager` and checks every 24 hours to see if any auto-generated legacy ServiceAccount token has not been used in a *specified amount of time*. If so, the cleaner marks those tokens as invalid.

The cleaner works by first checking the ConfigMap created by the control plane (provided that `LegacyServiceAccountTokenTracking` is enabled). If the current time is a *specified amount of time* after the date in the ConfigMap, the cleaner then loops through the list of Secrets in the cluster and evaluates each Secret that has the type `kubernetes.io/service-account-token`.

If a Secret meets all of the following conditions, the cleaner marks it as invalid:

- The Secret is auto-generated, meaning that it is bi-directionally referenced by a ServiceAccount.
- The Secret is not currently mounted by any pods.
- The Secret has not been used in a *specified amount of time* since it was created or since it was last used.

The cleaner marks a Secret invalid by adding a label called `kubernetes.io/legacy-token-invalid-since` to the Secret, with the current date as the value. If an invalid Secret is not used in a *specified amount of time*, the cleaner will delete it.

#### Note:

All the *specified amount of time* above defaults to one year. The cluster administrator can configure this value through the `--legacy-service-account-token-clean-up-period` command line argument for the `kube-controller-manager` component.

## TokenRequest API

FEATURE STATE: Kubernetes v1.22 [stable]

You use the [TokenRequest](#) subresource of a ServiceAccount to obtain a time-bound token for that ServiceAccount. You don't need to call this to obtain an API token for use within a container, since the kubelet sets this up for you using a *projected volume*.

If you want to use the TokenRequest API from `kubectl`, see [Manually create an API token for a ServiceAccount](#).

The Kubernetes control plane (specifically, the ServiceAccount admission controller) adds a projected volume to Pods, and the kubelet ensures that this volume contains a token that lets containers authenticate as the right ServiceAccount.

(This mechanism superseded an earlier mechanism that added a volume based on a Secret, where the Secret represented the ServiceAccount for the Pod but did not expire.)

Here's an example of how that looks for a launched Pod:

```
...
- name: kube-api-access-<random-suffix>
 projected:
 defaultMode: 420 # decimal equivalent of octal 0644
 sources:
 - serviceAccountToken:
 expirationSeconds: 3607
 path: token
 - configMap:
 items:
 - key: ca.crt
 path: ca.crt
 name: kube-root-ca.crt
 - downwardAPI:
 items:
 - fieldRef:
 apiVersion: v1
 fieldPath: metadata.namespace
 path: namespace
```

That manifest snippet defines a projected volume that combines information from three sources:

1. A serviceAccountToken source, that contains a token that the kubelet acquires from kube-apiserver. The kubelet fetches time-bound tokens using the TokenRequest API. A token served for a TokenRequest expires either when the pod is deleted or after a defined lifespan (by default, that is 1 hour). The token is bound to the specific Pod and has the kube-apiserver as its audience.
2. A configMap source. The ConfigMap contains a bundle of certificate authority data. Pods can use these certificates to make sure that they are connecting to your cluster's kube-apiserver (and not to middlebox or an accidentally misconfigured peer).
3. A downwardAPI source. This downwardAPI volume makes the name of the namespace containing the Pod available to application code running inside the Pod.

Any container within the Pod that mounts this volume can access the above information.

## Create additional API tokens

### Caution:

Only create long-lived API tokens if the [token request](#) mechanism is not suitable. The token request mechanism provides time-limited tokens; because these expire, they represent a lower risk to information security.

To create a non-expiring, persisted API token for a ServiceAccount, create a Secret of type `kubernetes.io/service-account-token` with an annotation referencing the ServiceAccount. The control plane then generates a long-lived token and updates that Secret with that generated token data.

Here is a sample manifest for such a Secret:

[secret/serviceaccount/mysecretname.yaml](#)

```
apiVersion: v1
kind: Secret
type: kubernetes.io/service-account-token
metadata:
 name: mysecretname
 annotations:
 kubernetes.io/service-account.name: myserviceaccount
```

To create a Secret based on this example, run:

```
kubectl -n examplens create -f https://k8s.io/examples/secret/serviceaccount/
mysecretname.yaml
```

To see the details for that Secret, run:

```
kubectl -n examplens describe secret mysecretname
```

The output is similar to:

```
Name: mysecretname
Namespace: examplens
Labels: <none>
Annotations: kubernetes.io/service-account.name=myserviceaccount
 kubernetes.io/service-account.uid=8a85c4c4-8483-11e9-bc42-526af7764f64

Type: kubernetes.io/service-account-token

Data
====
ca.crt: 1362 bytes
namespace: 9 bytes
token: ...
```

If you launch a new Pod into the examplens namespace, it can use the myserviceaccount service-account-token Secret that you just created.

### Caution:

Do not reference manually created Secrets in the secrets field of a ServiceAccount. Or the manually created Secrets will be cleaned if it is not used for a long time. Please refer to [auto-generated legacy ServiceAccount token clean up](#).

## Delete/invalidate a ServiceAccount token

If you know the name of the Secret that contains the token you want to remove:

```
kubectl delete secret name-of-secret
```

Otherwise, first find the Secret for the ServiceAccount.

```
This assumes that you already have a namespace named 'examplens'
kubectl -n examplens get serviceaccount/example-automated-thing -o yaml
```

The output is similar to:

```
apiVersion: v1
kind: ServiceAccount
metadata:
 annotations:
 kubectl.kubernetes.io/last-applied-configuration: |
 {"apiVersion":"v1","kind":"ServiceAccount","metadata":{"annotations":{},"name":"example-automated-thing","namespace":"examplens"}}
 creationTimestamp: "2019-07-21T07:07:07Z"
 name: example-automated-thing
 namespace: examplens
 resourceVersion: "777"
 selfLink: /api/v1/namespaces/examplens/serviceaccounts/example-automated-thing
 uid: f23fd170-66f2-4697-b049-e1e266b7f835
secrets:
 - name: example-automated-thing-token-zyxwv
```

Then, delete the Secret you now know the name of:

```
kubectl -n exemplens delete secret/example-automated-thing-token-zyxwv
```

## Clean up

If you created a namespace `exemplens` to experiment with, you can remove it:

```
kubectl delete namespace exemplens
```

## What's next

- Read more details about [projected volumes](#).

# Certificates and Certificate Signing Requests

Kubernetes certificate and trust bundle APIs enable automation of [X.509](#) credential provisioning by providing a programmatic interface for clients of the Kubernetes API to request and obtain X.509 [certificates](#) from a Certificate Authority (CA).

There is also experimental (alpha) support for distributing [trust bundles](#).

## Certificate signing requests

FEATURE STATE: Kubernetes v1.19 [stable]

A `CertificateSigningRequest` (CSR) resource is used to request that a certificate be signed by a denoted signer, after which the request may be approved or denied before finally being signed.

### Request signing process

The `CertificateSigningRequest` resource type allows a client to ask for an X.509 certificate be issued, based on a signing request. The `CertificateSigningRequest` object includes a PEM-encoded PKCS#10 signing request in the `spec.request` field. The `CertificateSigningRequest` denotes the signer (the recipient that the request is being made to) using the `spec.signerName` field. Note that `spec.signerName` is a required key after API version `certificates.k8s.io/v1`. In Kubernetes v1.22 and later, clients may optionally set the `spec.expirationSeconds` field to request a particular lifetime for the issued certificate. The minimum valid value for this field is 600, i.e. ten minutes.

Once created, a `CertificateSigningRequest` must be approved before it can be signed. Depending on the signer selected, a `CertificateSigningRequest` may be automatically approved by a [controller](#). Otherwise, a `CertificateSigningRequest` must be manually approved either via the REST API (or `client-go`) or by running `kubectl certificate approve`. Likewise, a `CertificateSigningRequest` may also be denied, which tells the configured signer that it must not sign the request.

For certificates that have been approved, the next step is signing. The relevant signing controller first validates that the signing conditions are met and then creates a certificate. The signing controller then updates the `CertificateSigningRequest`, storing the new certificate into

the `status.certificate` field of the existing `CertificateSigningRequest` object. The `status.certificate` field is either empty or contains a X.509 certificate, encoded in PEM format. The `CertificateSigningRequest` `status.certificate` field is empty until the signer does this.

Once the `status.certificate` field has been populated, the request has been completed and clients can now fetch the signed certificate PEM data from the `CertificateSigningRequest` resource. The signers can instead deny certificate signing if the approval conditions are not met.

In order to reduce the number of old `CertificateSigningRequest` resources left in a cluster, a garbage collection controller runs periodically. The garbage collection removes `CertificateSigningRequests` that have not changed state for some duration:

- Approved requests: automatically deleted after 1 hour
- Denied requests: automatically deleted after 1 hour
- Failed requests: automatically deleted after 1 hour
- Pending requests: automatically deleted after 24 hours
- All requests: automatically deleted after the issued certificate has expired

## Certificate signing authorization

To allow creating a `CertificateSigningRequest` and retrieving any `CertificateSigningRequest`:

- Verbs: create, get, list, watch, group: certificates.k8s.io, resource: certificatesigningrequests

For example:

[access/certificate-signing-request/clusterrole-create.yaml](#)

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: csr-creator
rules:
- apiGroups:
 - certificates.k8s.io
 resources:
 - certificatesigningrequests
 verbs:
 - create
 - get
 - list
 - watch
```

To allow approving a `CertificateSigningRequest`:

- Verbs: get, list, watch, group: certificates.k8s.io, resource: certificatesigningrequests
- Verbs: update, group: certificates.k8s.io, resource: certificatesigningrequests/approval
- Verbs: approve, group: certificates.k8s.io, resource: signers, resourceName: <signerNameDomain>/<signerNamePath> or <signerNameDomain>/\*

For example:

[access/certificate-signing-request/clusterrole-approve.yaml](#)

```

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: csr-approver
rules:
- apiGroups:
 - certificates.k8s.io
 resources:
 - certificatesigningrequests
 verbs:
 - get
 - list
 - watch
- apiGroups:
 - certificates.k8s.io
 resources:
 - certificatesigningrequests/approval
 verbs:
 - update
- apiGroups:
 - certificates.k8s.io
 resources:
 - signers
 resourceNames:
 - example.com/my-signer-name
example.com/* can be used to authorize for all signers in the 'example.com' domain
verbs:
- approve

```

To allow signing a CertificateSigningRequest:

- Verbs: get, list, watch, group: certificates.k8s.io, resource: certificatesigningrequests
- Verbs: update, group: certificates.k8s.io, resource: certificatesigningrequests/status
- Verbs: sign, group: certificates.k8s.io, resource: signers, resourceName: <signerNameDomain>/<signerNamePath> or <signerNameDomain>/\*

[access/certificate-signing-request/clusterrole-sign.yaml](#)

```

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: csr-signer
rules:
- apiGroups:
 - certificates.k8s.io
 resources:
 - certificatesigningrequests
 verbs:
 - get
 - list
 - watch
- apiGroups:

```

```
- certificates.k8s.io
resources:
- certificatesigningrequests/status
verbs:
- update
- apiGroups:
- certificates.k8s.io
resources:
- signers
resourceNames:
- example.com/my-signer-name
example.com/* can be used to authorize for all signers in the 'example.com' domain
verbs:
- sign
```

## Signers

Signers abstractly represent the entity or entities that might sign, or have signed, a security certificate.

Any signer that is made available for outside a particular cluster should provide information about how the signer works, so that consumers can understand what that means for CertificateSigningRequests and (if enabled) [ClusterTrustBundles](#).

This includes:

1. **Trust distribution:** how trust anchors (CA certificates or certificate bundles) are distributed.
2. **Permitted subjects:** any restrictions on and behavior when a disallowed subject is requested.
3. **Permitted x509 extensions:** including IP subjectAltNames, DNS subjectAltNames, Email subjectAltNames, URI subjectAltNames etc, and behavior when a disallowed extension is requested.
4. **Permitted key usages / extended key usages:** any restrictions on and behavior when usages different than the signer-determined usages are specified in the CSR.
5. **Expiration/certificate lifetime:** whether it is fixed by the signer, configurable by the admin, determined by the CSR spec.expirationSeconds field, etc and the behavior when the signer-determined expiration is different from the CSR spec.expirationSeconds field.
6. **CA bit allowed/disallowed:** and behavior if a CSR contains a request a for a CA certificate when the signer does not permit it.

Commonly, the status.certificate field of a CertificateSigningRequest contains a single PEM-encoded X.509 certificate once the CSR is approved and the certificate is issued. Some signers store multiple certificates into the status.certificate field. In that case, the documentation for the signer should specify the meaning of additional certificates; for example, this might be the certificate plus intermediates to be presented during TLS handshakes.

If you want to make the *trust anchor* (root certificate) available, this should be done separately from a CertificateSigningRequest and its status.certificate field. For example, you could use a ClusterTrustBundle.

The PKCS#10 signing request format does not have a standard mechanism to specify a certificate expiration or lifetime. The expiration or lifetime therefore has to be set through the spec.expirationSeconds field of the CSR object. The built-in signers use the

ClusterSigningDuration configuration option, which defaults to 1 year, (the --cluster-signing-duration command-line flag of the kube-controller-manager) as the default when no spec.expirationSeconds is specified. When spec.expirationSeconds is specified, the minimum of spec.expirationSeconds and ClusterSigningDuration is used.

**Note:**

The spec.expirationSeconds field was added in Kubernetes v1.22. Earlier versions of Kubernetes do not honor this field. Kubernetes API servers prior to v1.22 will silently drop this field when the object is created.

## Kubernetes signers

Kubernetes provides built-in signers that each have a well-known signerName:

1. `kubernetes.io/kube-apiserver-client`: signs certificates that will be honored as client certificates by the API server. Never auto-approved by [kube-controller-manager](#).
  1. Trust distribution: signed certificates must be honored as client certificates by the API server. The CA bundle is not distributed by any other means.
  2. Permitted subjects - no subject restrictions, but approvers and signers may choose not to approve or sign. Certain subjects like cluster-admin level users or groups vary between distributions and installations, but deserve additional scrutiny before approval and signing. The CertificateSubjectRestriction admission plugin is enabled by default to restrict system:masters, but it is often not the only cluster-admin subject in a cluster.
  3. Permitted x509 extensions - honors subjectAltName and key usage extensions and discards other extensions.
  4. Permitted key usages - must include ["client auth"]. Must not include key usages beyond ["digital signature", "key encipherment", "client auth"].
  5. Expiration/certificate lifetime - for the kube-controller-manager implementation of this signer, set to the minimum of the --cluster-signing-duration option or, if specified, the spec.expirationSeconds field of the CSR object.
  6. CA bit allowed/disallowed - not allowed.
2. `kubernetes.io/kube-apiserver-client-kubelet`: signs client certificates that will be honored as client certificates by the API server. May be auto-approved by [kube-controller-manager](#).
  1. Trust distribution: signed certificates must be honored as client certificates by the API server. The CA bundle is not distributed by any other means.
  2. Permitted subjects - organizations are exactly ["system:nodes"], common name starts with "system:node:".
  3. Permitted x509 extensions - honors key usage extensions, forbids subjectAltName extensions and drops other extensions.
  4. Permitted key usages - ["key encipherment", "digital signature", "client auth"] or ["digital signature", "client auth"].
  5. Expiration/certificate lifetime - for the kube-controller-manager implementation of this signer, set to the minimum of the --cluster-signing-duration option or, if specified, the spec.expirationSeconds field of the CSR object.
  6. CA bit allowed/disallowed - not allowed.

- kubernetes.io/kubelet-serving: signs serving certificates that are honored as a valid
3. kubelet serving certificate by the API server, but has no other guarantees. Never auto-approved by [kube-controller-manager](#).
    1. Trust distribution: signed certificates must be honored by the API server as valid to terminate connections to a kubelet. The CA bundle is not distributed by any other means.
    2. Permitted subjects - organizations are exactly ["system:nodes"], common name starts with "system:node:".
    3. Permitted x509 extensions - honors key usage and DNSName/IPAddress subjectAltName extensions, forbids EmailAddress and URI subjectAltName extensions, drops other extensions. At least one DNS or IP subjectAltName must be present.
    4. Permitted key usages - ["key encipherment", "digital signature", "server auth"] or ["digital signature", "server auth"].
    5. Expiration/certificate lifetime - for the kube-controller-manager implementation of this signer, set to the minimum of the --cluster-signing-duration option or, if specified, the spec.expirationSeconds field of the CSR object.
    6. CA bit allowed/disallowed - not allowed.
  4. kubernetes.io/legacy-unknown: has no guarantees for trust at all. Some third-party distributions of Kubernetes may honor client certificates signed by it. The stable CertificateSigningRequest API (version certificates.k8s.io/v1 and later) does not allow to set the signerName as kubernetes.io/legacy-unknown. Never auto-approved by [kube-controller-manager](#).
    1. Trust distribution: None. There is no standard trust or distribution for this signer in a Kubernetes cluster.
    2. Permitted subjects - any
    3. Permitted x509 extensions - honors subjectAltName and key usage extensions and discards other extensions.
    4. Permitted key usages - any
    5. Expiration/certificate lifetime - for the kube-controller-manager implementation of this signer, set to the minimum of the --cluster-signing-duration option or, if specified, the spec.expirationSeconds field of the CSR object.
    6. CA bit allowed/disallowed - not allowed.

The kube-controller-manager implements [control plane signing](#) for each of the built in signers. Failures for all of these are only reported in kube-controller-manager logs.

**Note:**

The spec.expirationSeconds field was added in Kubernetes v1.22. Earlier versions of Kubernetes do not honor this field. Kubernetes API servers prior to v1.22 will silently drop this field when the object is created.

Distribution of trust happens out of band for these signers. Any trust outside of those described above are strictly coincidental. For instance, some distributions may honor kubernetes.io/legacy-unknown as client certificates for the kube-apiserver, but this is not a standard. None of these usages are related to ServiceAccount token secrets .data[ca.crt] in any way. That CA bundle is only guaranteed to verify a connection to the API server using the default service (kubernetes.default.svc).

## Custom signers

You can also introduce your own custom signer, which should have a similar prefixed name but using your own domain name. For example, if you represent an open source project that uses the domain `open-fictional.example` then you might use `issuer.open-fictional.example/service-mesh` as a signer name.

A custom signer uses the Kubernetes API to issue a certificate. See [API-based signers](#).

## Signing

### Control plane signer

The Kubernetes control plane implements each of the [Kubernetes signers](#), as part of the kube-controller-manager.

#### Note:

Prior to Kubernetes v1.18, the kube-controller-manager would sign any CSRs that were marked as approved.

#### Note:

The `spec.expirationSeconds` field was added in Kubernetes v1.22. Earlier versions of Kubernetes do not honor this field. Kubernetes API servers prior to v1.22 will silently drop this field when the object is created.

### API-based signers

Users of the REST API can sign CSRs by submitting an UPDATE request to the status subresource of the CSR to be signed.

As part of this request, the `status.certificate` field should be set to contain the signed certificate. This field contains one or more PEM-encoded certificates.

All PEM blocks must have the "CERTIFICATE" label, contain no headers, and the encoded data must be a BER-encoded ASN.1 Certificate structure as described in [section 4 of RFC5280](#).

Example certificate content:

```
-----BEGIN CERTIFICATE-----
MIIDgjCCAmqgAwIBAgIUC1N1EJ4Qnsd322BhDPRwmg3b/oAwDQYJKoZIhvcNAQEL

M1fLPhLyR54fGaY+7/X8P9AZzPefAkwiseXwe9ii6/a08vWoiE4=
-----END CERTIFICATE-----
```

Non-PEM content may appear before or after the CERTIFICATE PEM blocks and is unvalidated, to allow for explanatory text as described in [section 5.2 of RFC7468](#).

When encoded in JSON or YAML, this field is base-64 encoded. A CertificateSigningRequest containing the example certificate above would look like this:

```
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
...
status:
 certificate: "LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JS..."
```

## Approval or rejection

Before a [signer](#) issues a certificate based on a CertificateSigningRequest, the signer typically checks that the issuance for that CSR has been *approved*.

### Control plane automated approval

The kube-controller-manager ships with a built-in approver for certificates with a signerName of kubernetes.io/kube-apiserver-client-kubelet that delegates various permissions on CSRs for node credentials to authorization. The kube-controller-manager POSTs SubjectAccessReview resources to the API server in order to check authorization for certificate approval.

### Approval or rejection using kubectl

A Kubernetes administrator (with appropriate permissions) can manually approve (or deny) CertificateSigningRequests by using the kubectl certificate approve and kubectl certificate deny commands.

To approve a CSR with kubectl:

```
kubectl certificate approve <certificate-signing-request-name>
```

Likewise, to deny a CSR:

```
kubectl certificate deny <certificate-signing-request-name>
```

## Approval or rejection using the Kubernetes API

Users of the REST API can approve CSRs by submitting an UPDATE request to the approval subresource of the CSR to be approved. For example, you could write an [operator](#) that watches for a particular kind of CSR and then sends an UPDATE to approve them.

When you make an approval or rejection request, set either the Approved or Denied status condition based on the state you determine:

For Approved CSRs:

```
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
...
status:
 conditions:
 - lastUpdateTime: "2020-02-08T11:37:35Z"
 lastTransitionTime: "2020-02-08T11:37:35Z"
 message: Approved by my custom approver controller
 reason: ApprovedByMyPolicy # You can set this to any string
 type: Approved
```

For Denied CSRs:

```
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
...
status:
 conditions:
 - lastUpdateTime: "2020-02-08T11:37:35Z"
 lastTransitionTime: "2020-02-08T11:37:35Z"
 message: Denied by my custom approver controller
 reason: DeniedByMyPolicy # You can set this to any string
 type: Denied
```

It's usual to set status.conditions.reason to a machine-friendly reason code using TitleCase; this is a convention but you can set it to anything you like. If you want to add a note for human consumption, use the status.conditions.message field.

## Cluster trust bundles

FEATURE STATE: Kubernetes v1.27 [alpha]

### Note:

In Kubernetes 1.30, you must enable the ClusterTrustBundle [feature gate](#) and the certificates.k8s.io/v1alpha1 [API group](#) in order to use this API.

A ClusterTrustBundles is a cluster-scoped object for distributing X.509 trust anchors (root certificates) to workloads within the cluster. They're designed to work well with the [signer](#) concept from CertificateSigningRequests.

ClusterTrustBundles can be used in two modes: [signer-linked](#) and [signer-unlinked](#).

## Common properties and validation

All ClusterTrustBundle objects have strong validation on the contents of their trustBundle field. That field must contain one or more X.509 certificates, DER-serialized, each wrapped in a PEM CERTIFICATE block. The certificates must parse as valid X.509 certificates.

Esoteric PEM features like inter-block data and intra-block headers are either rejected during object validation, or can be ignored by consumers of the object. Additionally, consumers are allowed to reorder the certificates in the bundle with their own arbitrary but stable ordering.

ClusterTrustBundle objects should be considered world-readable within the cluster. If your cluster uses [RBAC](#) authorization, all ServiceAccounts have a default grant that allows them to **get**, **list**, and **watch** all ClusterTrustBundle objects. If you use your own authorization mechanism and you have enabled ClusterTrustBundles in your cluster, you should set up an equivalent rule to make these objects public within the cluster, so that they work as intended.

If you do not have permission to list cluster trust bundles by default in your cluster, you can impersonate a service account you have access to in order to see available ClusterTrustBundles:

```
kubectl get clustertrustbundles --as='system:serviceaccount:mynamespace:default'
```

## Signer-linked ClusterTrustBundles

Signer-linked ClusterTrustBundles are associated with a *signer name*, like this:

```
apiVersion: certificates.k8s.io/v1alpha1
kind: ClusterTrustBundle
metadata:
 name: example.com:mysigner:foo
spec:
 signerName: example.com/mysigner
 trustBundle: "<... PEM data ...>"
```

These ClusterTrustBundles are intended to be maintained by a signer-specific controller in the cluster, so they have several security features:

- To create or update a signer-linked ClusterTrustBundle, you must be permitted to **attest** on the signer (custom authorization verb attest, API group certificates.k8s.io; resource path signers). You can configure authorization for the specific resource name `<signerNameDomain>/<signerNamePath>` or match a pattern such as `<signerNameDomain>/*`.
- Signer-linked ClusterTrustBundles **must** be named with a prefix derived from their spec.signerName field. Slashes (/) are replaced with colons (:), and a final colon is appended. This is followed by an arbitrary name. For example, the signer example.com/mysigner can be linked to a ClusterTrustBundle example.com:mysigner:<arbitrary-name>.

Signer-linked ClusterTrustBundles will typically be consumed in workloads by a combination of a [field selector](#) on the signer name, and a separate [label selector](#).

## Signer-unlinked ClusterTrustBundles

Signer-unlinked ClusterTrustBundles have an empty spec.signerName field, like this:

```
apiVersion: certificates.k8s.io/v1alpha1
kind: ClusterTrustBundle
metadata:
 name: foo
spec:
 # no signerName specified, so the field is blank
 trustBundle: "<... PEM data ...>"
```

They are primarily intended for cluster configuration use cases. Each signer-unlinked ClusterTrustBundle is an independent object, in contrast to the customary grouping behavior of signer-linked ClusterTrustBundles.

Signer-unlinked ClusterTrustBundles have no attest verb requirement. Instead, you control access to them directly using the usual mechanisms, such as role-based access control.

To distinguish them from signer-linked ClusterTrustBundles, the names of signer-unlinked ClusterTrustBundles **must not** contain a colon (:).

## Accessing ClusterTrustBundles from pods

FEATURE STATE: Kubernetes v1.29 [alpha]

The contents of ClusterTrustBundles can be injected into the container filesystem, similar to ConfigMaps and Secrets. See the [clusterTrustBundle projected volume source](#) for more details.

## How to issue a certificate for a user

A few steps are required in order to get a normal user to be able to authenticate and invoke an API. First, this user must have a certificate issued by the Kubernetes cluster, and then present that certificate to the Kubernetes API.

### Create private key

The following scripts show how to generate PKI private key and CSR. It is important to set CN and O attribute of the CSR. CN is the name of the user and O is the group that this user will belong to. You can refer to [RBAC](#) for standard groups.

```
openssl genrsa -out myuser.key 2048
openssl req -new -key myuser.key -out myuser.csr -subj "/CN=myuser"
```

### Create a CertificateSigningRequest

Create a CertificateSigningRequest and submit it to a Kubernetes Cluster via kubectl. Below is a script to generate the CertificateSigningRequest.

```
cat <<EOF | kubectl apply -f -
apiVersion: certificates.k8s.io/v1
kind: CertificateSigningRequest
metadata:
 name: myuser
spec:
 request:
```

```

lA3SVFjZmg3d0drWm89Ci0tLS0tRU5EIEENFUIRJRklDQVRFIJFUVVFU1QtLS0tLQo=
signerName: kubernetes.io/kube-apiserver-client
expirationSeconds: 86400 # one day
usages:
- client auth
EOF
```

Some points to note:

- usages has to be 'client auth'
- expirationSeconds could be made longer (i.e. 864000 for ten days) or shorter (i.e. 3600 for one hour)
- request is the base64 encoded value of the CSR file content. You can get the content using this command:

```
cat myuser.csr | base64 | tr -d "\n"
```

## Approve the CertificateSigningRequest

Use kubectl to create a CSR and approve it.

Get the list of CSRs:

```
kubectl get csr
```

Approve the CSR:

```
kubectl certificate approve myuser
```

## Get the certificate

Retrieve the certificate from the CSR:

```
kubectl get csr/myuser -o yaml
```

The certificate value is in Base64-encoded format under status.certificate.

Export the issued certificate from the CertificateSigningRequest.

```
kubectl get csr myuser -o jsonpath='{.status.certificate}' | base64 -d > myuser.crt
```

## Create Role and RoleBinding

With the certificate created it is time to define the Role and RoleBinding for this user to access Kubernetes cluster resources.

This is a sample command to create a Role for this new user:

```
kubectl create role developer --verb=create --verb=get --verb=list --verb=update --verb=delete --resource=pods
```

This is a sample command to create a RoleBinding for this new user:

```
kubectl create rolebinding developer-binding-myuser --role=developer --user=myuser
```

## Add to kubeconfig

The last step is to add this user into the kubeconfig file.

First, you need to add new credentials:

```
kubectl config set-credentials myuser --client-key=myuser.key --client-certificate=myuser.crt --embed-certs=true
```

Then, you need to add the context:

```
kubectl config set-context myuser --cluster=kubernetes --user=myuser
```

To test it, change the context to myuser:

```
kubectl config use-context myuser
```

# Mapping PodSecurityPolicies to Pod Security Standards

The tables below enumerate the configuration parameters on PodSecurityPolicy objects, whether the field mutates and/or validates pods, and how the configuration values map to the [Pod Security Standards](#).

For each applicable parameter, the allowed values for the [Baseline](#) and [Restricted](#) profiles are listed. Anything outside the allowed values for those profiles would fall under the [Privileged](#) profile. "No opinion" means all values are allowed under all Pod Security Standards.

For a step-by-step migration guide, see [Migrate from PodSecurityPolicy to the Built-In PodSecurity Admission Controller](#).

## PodSecurityPolicy Spec

The fields enumerated in this table are part of the PodSecurityPolicySpec, which is specified under the .spec field path.

Mapping PodSecurityPolicySpec fields to Pod Security Standards

| PodSecurityPolicySpec    | Type                  | Pod Security Standards Equivalent                                                                                                                                                                                                                                                                                                                                                                                   |

## Kubelet authentication/authorization

### Overview

A kubelet's HTTPS endpoint exposes APIs which give access to data of varying sensitivity, and allow you to perform operations with varying levels of power on the node and within containers.

This document describes how to authenticate and authorize access to the kubelet's HTTPS endpoint.

## Kubelet authentication

By default, requests to the kubelet's HTTPS endpoint that are not rejected by other configured authentication methods are treated as anonymous requests, and given a username of `system:anonymous` and a group of `system:unauthenticated`.

To disable anonymous access and send 401 Unauthorized responses to unauthenticated requests:

- start the kubelet with the `--anonymous-auth=false` flag

To enable X509 client certificate authentication to the kubelet's HTTPS endpoint:

- start the kubelet with the `--client-ca-file` flag, providing a CA bundle to verify client certificates with
- start the apiserver with `--kubelet-client-certificate` and `--kubelet-client-key` flags
- see the [apiserver authentication documentation](#) for more details

To enable API bearer tokens (including service account tokens) to be used to authenticate to the kubelet's HTTPS endpoint:

- ensure the `authentication.k8s.io/v1beta1` API group is enabled in the API server
- start the kubelet with the `--authentication-token-webhook` and `--kubeconfig` flags
- the kubelet calls the `TokenReview` API on the configured API server to determine user information from bearer tokens

## Kubelet authorization

Any request that is successfully authenticated (including an anonymous request) is then authorized. The default authorization mode is `AlwaysAllow`, which allows all requests.

There are many possible reasons to subdivide access to the kubelet API:

- anonymous auth is enabled, but anonymous users' ability to call the kubelet API should be limited
- bearer token auth is enabled, but arbitrary API users' (like service accounts) ability to call the kubelet API should be limited
- client certificate auth is enabled, but only some of the client certificates signed by the configured CA should be allowed to use the kubelet API

To subdivide access to the kubelet API, delegate authorization to the API server:

- ensure the `authorization.k8s.io/v1beta1` API group is enabled in the API server
- start the kubelet with the `--authorization-mode=Webhook` and the `--kubeconfig` flags
- the kubelet calls the `SubjectAccessReview` API on the configured API server to determine whether each request is authorized

The kubelet authorizes API requests using the same [request attributes](#) approach as the apiserver.

The verb is determined from the incoming request's HTTP verb:

| HTTP verb | request verb |
|-----------|--------------|
| POST      | create       |
| GET, HEAD | get          |
| PUT       | update       |
| PATCH     | patch        |
| DELETE    | delete       |

The resource and subresource is determined from the incoming request's path:

| Kubelet API       | resource | subresource |
|-------------------|----------|-------------|
| /stats/*          | nodes    | stats       |
| /metrics/*        | nodes    | metrics     |
| /logs/*           | nodes    | log         |
| /spec/*           | nodes    | spec        |
| <i>all others</i> | nodes    | proxy       |

The namespace and API group attributes are always an empty string, and the resource name is always the name of the kubelet's Node API object.

When running in this mode, ensure the user identified by the `--kubelet-client-certificate` and `--kubelet-client-key` flags passed to the apiserver is authorized for the following attributes:

- verb=\*, resource=nodes, subresource=proxy
- verb=\*, resource=nodes, subresource=stats
- verb=\*, resource=nodes, subresource=log
- verb=\*, resource=nodes, subresource=spec
- verb=\*, resource=nodes, subresource=metrics

## TLS bootstrapping

In a Kubernetes cluster, the components on the worker nodes - kubelet and kube-proxy - need to communicate with Kubernetes control plane components, specifically kube-apiserver. In order to ensure that communication is kept private, not interfered with, and ensure that each component of the cluster is talking to another trusted component, we strongly recommend using client TLS certificates on nodes.

The normal process of bootstrapping these components, especially worker nodes that need certificates so they can communicate safely with kube-apiserver, can be a challenging process as it is often outside of the scope of Kubernetes and requires significant additional work. This in turn, can make it challenging to initialize or scale a cluster.

In order to simplify the process, beginning in version 1.4, Kubernetes introduced a certificate request and signing API. The proposal can be found [here](#).

This document describes the process of node initialization, how to set up TLS client certificate bootstrapping for kubelets, and how it works.

# Initialization process

When a worker node starts up, the kubelet does the following:

1. Look for its kubeconfig file
2. Retrieve the URL of the API server and credentials, normally a TLS key and signed certificate from the kubeconfig file
3. Attempt to communicate with the API server using the credentials.

Assuming that the kube-apiserver successfully validates the kubelet's credentials, it will treat the kubelet as a valid node, and begin to assign pods to it.

Note that the above process depends upon:

- Existence of a key and certificate on the local host in the kubeconfig
- The certificate having been signed by a Certificate Authority (CA) trusted by the kube-apiserver

All of the following are responsibilities of whoever sets up and manages the cluster:

1. Creating the CA key and certificate
2. Distributing the CA certificate to the control plane nodes, where kube-apiserver is running
3. Creating a key and certificate for each kubelet; strongly recommended to have a unique one, with a unique CN, for each kubelet
4. Signing the kubelet certificate using the CA key
5. Distributing the kubelet key and signed certificate to the specific node on which the kubelet is running

The TLS Bootstrapping described in this document is intended to simplify, and partially or even completely automate, steps 3 onwards, as these are the most common when initializing or scaling a cluster.

## Bootstrap initialization

In the bootstrap initialization process, the following occurs:

1. kubelet begins
2. kubelet sees that it does *not* have a kubeconfig file
3. kubelet searches for and finds a bootstrap-kubeconfig file
4. kubelet reads its bootstrap file, retrieving the URL of the API server and a limited usage "token"
5. kubelet connects to the API server, authenticates using the token
6. kubelet now has limited credentials to create and retrieve a certificate signing request (CSR)
7. kubelet creates a CSR for itself with the signerName set to kubernetes.io/kube-apiserver-client-kubelet
8. CSR is approved in one of two ways:
  - If configured, kube-controller-manager automatically approves the CSR
  - If configured, an outside process, possibly a person, approves the CSR using the Kubernetes API or via kubectl
9. Certificate is created for the kubelet
10. Certificate is issued to the kubelet

11. kubelet retrieves the certificate
12. kubelet creates a proper kubeconfig with the key and signed certificate
13. kubelet begins normal operation
14. Optional: if configured, kubelet automatically requests renewal of the certificate when it is close to expiry
15. The renewed certificate is approved and issued, either automatically or manually, depending on configuration.

The rest of this document describes the necessary steps to configure TLS Bootstrapping, and its limitations.

## Configuration

To configure for TLS bootstrapping and optional automatic approval, you must configure options on the following components:

- kube-apiserver
- kube-controller-manager
- kubelet
- in-cluster resources: ClusterRoleBinding and potentially ClusterRole

In addition, you need your Kubernetes Certificate Authority (CA).

## Certificate Authority

As without bootstrapping, you will need a Certificate Authority (CA) key and certificate. As without bootstrapping, these will be used to sign the kubelet certificate. As before, it is your responsibility to distribute them to control plane nodes.

For the purposes of this document, we will assume these have been distributed to control plane nodes at `/var/lib/kubernetes/ca.pem` (certificate) and `/var/lib/kubernetes/ca-key.pem` (key). We will refer to these as "Kubernetes CA certificate and key".

All Kubernetes components that use these certificates - kubelet, kube-apiserver, kube-controller-manager - assume the key and certificate to be PEM-encoded.

## kube-apiserver configuration

The kube-apiserver has several requirements to enable TLS bootstrapping:

- Recognizing CA that signs the client certificate
- Authenticating the bootstrapping kubelet to the `system:bootstrappers` group
- Authorize the bootstrapping kubelet to create a certificate signing request (CSR)

### Recognizing client certificates

This is normal for all client certificate authentication. If not already set, add the `--client-ca-file=FILENAME` flag to the kube-apiserver command to enable client certificate authentication, referencing a certificate authority bundle containing the signing certificate, for example `--client-ca-file=/var/lib/kubernetes/ca.pem`.

## Initial bootstrap authentication

In order for the bootstrapping kubelet to connect to kube-apiserver and request a certificate, it must first authenticate to the server. You can use any [authenticator](#) that can authenticate the kubelet.

While any authentication strategy can be used for the kubelet's initial bootstrap credentials, the following two authenticators are recommended for ease of provisioning.

1. [Bootstrap Tokens](#)
2. [Token authentication file](#)

Using bootstrap tokens is a simpler and more easily managed method to authenticate kubelets, and does not require any additional flags when starting kube-apiserver.

Whichever method you choose, the requirement is that the kubelet be able to authenticate as a user with the rights to:

1. create and retrieve CSRs
2. be automatically approved to request node client certificates, if automatic approval is enabled.

A kubelet authenticating using bootstrap tokens is authenticated as a user in the group `system:bootstrappers`, which is the standard method to use.

As this feature matures, you should ensure tokens are bound to a Role Based Access Control (RBAC) policy which limits requests (using the [bootstrap token](#)) strictly to client requests related to certificate provisioning. With RBAC in place, scoping the tokens to a group allows for great flexibility. For example, you could disable a particular bootstrap group's access when you are done provisioning the nodes.

### Bootstrap tokens

Bootstrap tokens are described in detail [here](#). These are tokens that are stored as secrets in the Kubernetes cluster, and then issued to the individual kubelet. You can use a single token for an entire cluster, or issue one per worker node.

The process is two-fold:

1. Create a Kubernetes secret with the token ID, secret and scope(s).
2. Issue the token to the kubelet

From the kubelet's perspective, one token is like another and has no special meaning. From the kube-apiserver's perspective, however, the bootstrap token is special. Due to its type, namespace and name, kube-apiserver recognizes it as a special token, and grants anyone authenticating with that token special bootstrap rights, notably treating them as a member of the `system:bootstrappers` group. This fulfills a basic requirement for TLS bootstrapping.

The details for creating the secret are available [here](#).

If you want to use bootstrap tokens, you must enable it on kube-apiserver with the flag:

```
--enable-bootstrap-token-auth=true
```

## Token authentication file

kube-apiserver has the ability to accept tokens as authentication. These tokens are arbitrary but should represent at least 128 bits of entropy derived from a secure random number generator (such as `/dev/urandom` on most modern Linux systems). There are multiple ways you can generate a token. For example:

```
head -c 16 /dev/urandom | od -An -t x | tr -d ' '
```

This will generate tokens that look like `02b50b05283e98dd0fd71db496ef01e8`.

The token file should look like the following example, where the first three values can be anything and the quoted group name should be as depicted:

```
02b50b05283e98dd0fd71db496ef01e8,kubelet-bootstrap,10001,"system:bootstrappers"
```

Add the `--token-auth-file=FILENAME` flag to the kube-apiserver command (in your systemd unit file perhaps) to enable the token file. See docs [here](#) for further details.

## Authorize kubelet to create CSR

Now that the bootstrapping node is *authenticated* as part of the `system:bootstrappers` group, it needs to be *authorized* to create a certificate signing request (CSR) as well as retrieve it when done. Fortunately, Kubernetes ships with a ClusterRole with precisely these (and only these) permissions, `system:node-bootstrapper`.

To do this, you only need to create a ClusterRoleBinding that binds the `system:bootstrappers` group to the cluster role `system:node-bootstrapper`.

```
enable bootstrapping nodes to create CSR
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
 name: create-csrs-for-bootstrapping
subjects:
- kind: Group
 name: system:bootstrappers
 apiGroup: rbac.authorization.k8s.io
roleRef:
 kind: ClusterRole
 name: system:node-bootstrapper
 apiGroup: rbac.authorization.k8s.io
```

## kube-controller-manager configuration

While the apiserver receives the requests for certificates from the kubelet and authenticates those requests, the controller-manager is responsible for issuing actual signed certificates.

The controller-manager performs this function via a certificate-issuing control loop. This takes the form of a [cfssl](#) local signer using assets on disk. Currently, all certificates issued have one year validity and a default set of key usages.

In order for the controller-manager to sign certificates, it needs the following:

- access to the "Kubernetes CA key and certificate" that you created and distributed
- enabling CSR signing

## Access to key and certificate

As described earlier, you need to create a Kubernetes CA key and certificate, and distribute it to the control plane nodes. These will be used by the controller-manager to sign the kubelet certificates.

Since these signed certificates will, in turn, be used by the kubelet to authenticate as a regular kubelet to kube-apiserver, it is important that the CA provided to the controller-manager at this stage also be trusted by kube-apiserver for authentication. This is provided to kube-apiserver with the flag `--client-ca-file=FILENAME` (for example, `--client-ca-file=/var/lib/kubernetes/ca.pem`), as described in the kube-apiserver configuration section.

To provide the Kubernetes CA key and certificate to kube-controller-manager, use the following flags:

```
--cluster-signing-cert-file="/etc/path/to/kubernetes/ca/ca.crt" --cluster-signing-key-file="/etc/path/to/kubernetes/ca/ca.key"
```

For example:

```
--cluster-signing-cert-file="/var/lib/kubernetes/ca.pem" --cluster-signing-key-file="/var/lib/kubernetes/ca-key.pem"
```

The validity duration of signed certificates can be configured with flag:

```
--cluster-signing-duration
```

## Approval

In order to approve CSRs, you need to tell the controller-manager that it is acceptable to approve them. This is done by granting RBAC permissions to the correct group.

There are two distinct sets of permissions:

- `nodeclient`: If a node is creating a new certificate for a node, then it does not have a certificate yet. It is authenticating using one of the tokens listed above, and thus is part of the group `system:bootstrappers`.
- `selfnodeclient`: If a node is renewing its certificate, then it already has a certificate (by definition), which it uses continuously to authenticate as part of the group `system:nodes`.

To enable the kubelet to request and receive a new certificate, create a `ClusterRoleBinding` that binds the group in which the bootstrapping node is a member `system:bootstrappers` to the `ClusterRole` that grants it permission, `system:certificates.k8s.io:certificatesigningrequests:nodeclient`:

```
Approve all CSRs for the group "system:bootstrappers"
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
```

```
name: auto-approve-csrs-for-group
subjects:
- kind: Group
 name: system:bootstrappers
 apiGroup: rbac.authorization.k8s.io
roleRef:
 kind: ClusterRole
 name: system:certificates.k8s.io:certificatesigningrequests:nodeclient
 apiGroup: rbac.authorization.k8s.io
```

To enable the kubelet to renew its own client certificate, create a ClusterRoleBinding that binds the group in which the fully functioning node is a member system:nodes to the ClusterRole that grants it permission, system:certificates.k8s.io:certificatesigningrequests:selfnodeclient:

```
Approve renewal CSRs for the group "system:nodes"
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
 name: auto-approve-renewals-for-nodes
subjects:
- kind: Group
 name: system:nodes
 apiGroup: rbac.authorization.k8s.io
roleRef:
 kind: ClusterRole
 name: system:certificates.k8s.io:certificatesigningrequests:selfnodeclient
 apiGroup: rbac.authorization.k8s.io
```

The csrapproving controller that ships as part of [kube-controller-manager](#) and is enabled by default. The controller uses the [SubjectAccessReview API](#) to determine if a given user is authorized to request a CSR, then approves based on the authorization outcome. To prevent conflicts with other approvers, the built-in approver doesn't explicitly deny CSRs. It only ignores unauthorized requests. The controller also prunes expired certificates as part of garbage collection.

## kubelet configuration

Finally, with the control plane nodes properly set up and all of the necessary authentication and authorization in place, we can configure the kubelet.

The kubelet requires the following configuration to bootstrap:

- A path to store the key and certificate it generates (optional, can use default)
- A path to a kubeconfig file that does not yet exist; it will place the bootstrapped config file here
- A path to a bootstrap kubeconfig file to provide the URL for the server and bootstrap credentials, e.g. a bootstrap token
- Optional: instructions to rotate certificates

The bootstrap kubeconfig should be in a path available to the kubelet, for example /var/lib/kubelet/bootstrap-kubeconfig.

Its format is identical to a normal kubeconfig file. A sample file might look as follows:

```

apiVersion: v1
kind: Config
clusters:
- cluster:
 certificate-authority: /var/lib/kubernetes/ca.pem
 server: https://my.server.example.com:6443
 name: bootstrap
contexts:
- context:
 cluster: bootstrap
 user: kubelet-bootstrap
 name: bootstrap
current-context: bootstrap
preferences: {}
users:
- name: kubelet-bootstrap
 user:
 token: 07401b.f395accd246ae52d

```

The important elements to note are:

- `certificate-authority`: path to a CA file, used to validate the server certificate presented by kube-apiserver
- `server`: URL to kube-apiserver
- `token`: the token to use

The format of the token does not matter, as long as it matches what kube-apiserver expects. In the above example, we used a bootstrap token. As stated earlier, *any* valid authentication method can be used, not only tokens.

Because the bootstrap kubeconfig is a standard kubeconfig, you can use `kubect` to generate it. To create the above example file:

```

kubect config --kubeconfig=/var/lib/kubelet/bootstrap-kubeconfig set-cluster bootstrap --
server='https://my.server.example.com:6443' --certificate-authority=/var/lib/kubernetes/ca.pem
kubect config --kubeconfig=/var/lib/kubelet/bootstrap-kubeconfig set-credentials kubelet-
bootstrap --token=07401b.f395accd246ae52d
kubect config --kubeconfig=/var/lib/kubelet/bootstrap-kubeconfig set-context bootstrap --
user=kubelet-bootstrap --cluster=bootstrap
kubect config --kubeconfig=/var/lib/kubelet/bootstrap-kubeconfig use-context bootstrap

```

To indicate to the kubelet to use the bootstrap kubeconfig, use the following kubelet flag:

```

--bootstrap-kubeconfig="/var/lib/kubelet/bootstrap-kubeconfig" --kubeconfig="/var/lib/kubelet/
kubeconfig"

```

When starting the kubelet, if the file specified via `--kubeconfig` does not exist, the bootstrap kubeconfig specified via `--bootstrap-kubeconfig` is used to request a client certificate from the API server. On approval of the certificate request and receipt back by the kubelet, a kubeconfig file referencing the generated key and obtained certificate is written to the path specified by `--kubeconfig`. The certificate and key file will be placed in the directory specified by `--cert-dir`.

## Client and serving certificates

All of the above relate to kubelet *client* certificates, specifically, the certificates a kubelet uses to authenticate to kube-apiserver.

A kubelet also can use *serving* certificates. The kubelet itself exposes an https endpoint for certain features. To secure these, the kubelet can do one of:

- use provided key and certificate, via the `--tls-private-key-file` and `--tls-cert-file` flags
- create self-signed key and certificate, if a key and certificate are not provided
- request serving certificates from the cluster server, via the CSR API

The client certificate provided by TLS bootstrapping is signed, by default, for client auth only, and thus cannot be used as serving certificates, or server auth.

However, you *can* enable its server certificate, at least partially, via certificate rotation.

## Certificate rotation

Kubernetes v1.8 and higher kubelet implements features for enabling rotation of its client and/or serving certificates. Note, rotation of serving certificate is a **beta** feature and requires the `RotateKubeletServerCertificate` feature flag on the kubelet (enabled by default).

You can configure the kubelet to rotate its client certificates by creating new CSRs as its existing credentials expire. To enable this feature, use the `rotateCertificates` field of [kubelet configuration file](#) or pass the following command line argument to the kubelet (deprecated):

```
--rotate-certificates
```

Enabling `RotateKubeletServerCertificate` causes the kubelet **both** to request a serving certificate after bootstrapping its client credentials **and** to rotate that certificate. To enable this behavior, use the field `serverTLSBootstrap` of the [kubelet configuration file](#) or pass the following command line argument to the kubelet (deprecated):

```
--rotate-server-certificates
```

### Note:

The CSR approving controllers implemented in core Kubernetes do not approve node *serving* certificates for [security reasons](#). To use `RotateKubeletServerCertificate` operators need to run a custom approving controller, or manually approve the serving certificate requests.

A deployment-specific approval process for kubelet serving certificates should typically only approve CSRs which:

1. are requested by nodes (ensure the `spec.username` field is of the form `system:node:<nodeName>` and `spec.groups` contains `system:nodes`)
2. request usages for a serving certificate (ensure `spec.usages` contains `server auth`, optionally contains `digital signature` and `key encipherment`, and contains no other usages)
3. only have IP and DNS `subjectAltNames` that belong to the requesting node, and have no URI and Email `subjectAltNames` (parse the x509 Certificate Signing Request in `spec.request` to verify `subjectAltNames`)

## Other authenticating components

All of TLS bootstrapping described in this document relates to the kubelet. However, other components may need to communicate directly with kube-apiserver. Notable is kube-proxy, which is part of the Kubernetes node components and runs on every node, but may also include other components such as monitoring or networking.

Like the kubelet, these other components also require a method of authenticating to kube-apiserver. You have several options for generating these credentials:

- The old way: Create and distribute certificates the same way you did for kubelet before TLS bootstrapping
- DaemonSet: Since the kubelet itself is loaded on each node, and is sufficient to start base services, you can run kube-proxy and other node-specific services not as a standalone process, but rather as a daemonset in the kube-system namespace. Since it will be in-cluster, you can give it a proper service account with appropriate permissions to perform its activities. This may be the simplest way to configure such services.

## kubectl approval

CSRs can be approved outside of the approval flows built into the controller manager.

The signing controller does not immediately sign all certificate requests. Instead, it waits until they have been flagged with an "Approved" status by an appropriately-privileged user. This flow is intended to allow for automated approval handled by an external approval controller or the approval controller implemented in the core controller-manager. However cluster administrators can also manually approve certificate requests using kubectl. An administrator can list CSRs with `kubectl get csr` and describe one in detail with `kubectl describe csr <name>`. An administrator can approve or deny a CSR with `kubectl certificate approve <name>` and `kubectl certificate deny <name>`.

## Validating Admission Policy

FEATURE STATE: Kubernetes v1.30 [stable]

This page provides an overview of Validating Admission Policy.

### What is Validating Admission Policy?

Validating admission policies offer a declarative, in-process alternative to validating admission webhooks.

Validating admission policies use the Common Expression Language (CEL) to declare the validation rules of a policy. Validation admission policies are highly configurable, enabling policy authors to define policies that can be parameterized and scoped to resources as needed by cluster administrators.

# What Resources Make a Policy

A policy is generally made up of three resources:

- The `ValidatingAdmissionPolicy` describes the abstract logic of a policy (think: "this policy makes sure a particular label is set to a particular value").
- A `ValidatingAdmissionPolicyBinding` links the above resources together and provides scoping. If you only want to require an `owner` label to be set for Pods, the binding is where you would specify this restriction.
- A parameter resource provides information to a `ValidatingAdmissionPolicy` to make it a concrete statement (think "the owner label must be set to something that ends in `.company.com`"). A native type such as `ConfigMap` or a CRD defines the schema of a parameter resource. `ValidatingAdmissionPolicy` objects specify what Kind they are expecting for their parameter resource.

At least a `ValidatingAdmissionPolicy` and a corresponding `ValidatingAdmissionPolicyBinding` must be defined for a policy to have an effect.

If a `ValidatingAdmissionPolicy` does not need to be configured via parameters, simply leave `spec.paramKind` in `ValidatingAdmissionPolicy` not specified.

## Before you begin

- Ensure the `ValidatingAdmissionPolicy` [feature gate](#) is enabled.
- Ensure that the `admissionregistration.k8s.io/v1beta1` API is enabled.

## Getting Started with Validating Admission Policy

Validating Admission Policy is part of the cluster control-plane. You should write and deploy them with great caution. The following describes how to quickly experiment with Validating Admission Policy.

### Creating a ValidatingAdmissionPolicy

The following is an example of a `ValidatingAdmissionPolicy`.

[validatingadmissionpolicy/basic-example-policy.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "demo-policy.example.com"
spec:
 failurePolicy: Fail
 matchConstraints:
 resourceRules:
 - apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
```

```
resources: ["deployments"]
validations:
- expression: "object.spec.replicas <= 5"
```

spec.validations contains CEL expressions which use the [Common Expression Language \(CEL\)](#) to validate the request. If an expression evaluates to false, the validation check is enforced according to the spec.failurePolicy field.

### Note:

You can quickly test CEL expressions in [CEL Playground](#).

To configure a validating admission policy for use in a cluster, a binding is required. The following is an example of a ValidatingAdmissionPolicyBinding.:

[validatingadmissionpolicy/basic-example-binding.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicyBinding
metadata:
 name: "demo-binding-test.example.com"
spec:
 policyName: "demo-policy.example.com"
 validationActions: [Deny]
 matchResources:
 namespaceSelector:
 matchLabels:
 environment: test
```

When trying to create a deployment with replicas set not satisfying the validation expression, an error will return containing message:

```
ValidatingAdmissionPolicy 'demo-policy.example.com' with binding 'demo-binding-test.example.com' denied request: failed expression: object.spec.replicas <= 5
```

The above provides a simple example of using ValidatingAdmissionPolicy without a parameter configured.

### Validation actions

Each ValidatingAdmissionPolicyBinding must specify one or more validationActions to declare how validations of a policy are enforced.

The supported validationActions are:

- Deny: Validation failure results in a denied request.
- Warn: Validation failure is reported to the request client as a [warning](#).
- Audit: Validation failure is included in the audit event for the API request.

For example, to both warn clients about a validation failure and to audit the validation failures, use:

```
validationActions: [Warn, Audit]
```

Deny and Warn may not be used together since this combination needlessly duplicates the validation failure both in the API response body and the HTTP warning headers.

A validation that evaluates to false is always enforced according to these actions. Failures defined by the failurePolicy are enforced according to these actions only if the failurePolicy is set to Fail (or not specified), otherwise the failures are ignored.

See [Audit Annotations: validation failures](#) for more details about the validation failure audit annotation.

## Parameter resources

Parameter resources allow a policy configuration to be separate from its definition. A policy can define paramKind, which outlines GVK of the parameter resource, and then a policy binding ties a policy by name (via policyName) to a particular parameter resource via paramRef.

If parameter configuration is needed, the following is an example of a ValidatingAdmissionPolicy with parameter configuration.

[validatingadmissionpolicy/policy-with-param.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "replicalimit-policy.example.com"
spec:
 failurePolicy: Fail
 paramKind:
 apiVersion: rules.example.com/v1
 kind: ReplicaLimit
 matchConstraints:
 resourceRules:
 - apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments"]
 validations:
 - expression: "object.spec.replicas <= params.maxReplicas"
 reason: Invalid
```

The spec.paramKind field of the ValidatingAdmissionPolicy specifies the kind of resources used to parameterize this policy. For this example, it is configured by ReplicaLimit custom resources. Note in this example how the CEL expression references the parameters via the CEL params variable, e.g. params.maxReplicas. spec.matchConstraints specifies what resources this policy is designed to validate. Note that the native types such like ConfigMap could also be used as parameter reference.

The spec.validations fields contain CEL expressions. If an expression evaluates to false, the validation check is enforced according to the spec.failurePolicy field.

The validating admission policy author is responsible for providing the ReplicaLimit parameter CRD.

To configure an validating admission policy for use in a cluster, a binding and parameter resource are created. The following is an example of a ValidatingAdmissionPolicyBinding that uses a **cluster-wide** param - the same param will be used to validate every resource request that matches the binding:

[validatingadmissionpolicy/binding-with-param.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicyBinding
metadata:
 name: "replicalimit-binding-test.example.com"
spec:
 policyName: "replicalimit-policy.example.com"
 validationActions: [Deny]
 paramRef:
 name: "replica-limit-test.example.com"
 namespace: "default"
 matchResources:
 namespaceSelector:
 matchLabels:
 environment: test
```

Notice this binding applies a parameter to the policy for all resources which are in the test environment.

The parameter resource could be as following:

[validatingadmissionpolicy/replicalimit-param.yaml](#)

```
apiVersion: rules.example.com/v1
kind: ReplicaLimit
metadata:
 name: "replica-limit-test.example.com"
 namespace: "default"
maxReplicas: 3
```

This policy parameter resource limits deployments to a max of 3 replicas.

An admission policy may have multiple bindings. To bind all other environments to have a maxReplicas limit of 100, create another ValidatingAdmissionPolicyBinding:

[validatingadmissionpolicy/binding-with-param-prod.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicyBinding
metadata:
 name: "replicalimit-binding-nontest"
spec:
 policyName: "replicalimit-policy.example.com"
 validationActions: [Deny]
 paramRef:
 name: "replica-limit-prod.example.com"
 namespace: "default"
 matchResources:
```

```
namespaceSelector:
 matchExpressions:
 - key: environment
 operator: NotIn
 values:
 - test
```

Notice this binding applies a different parameter to resources which are not in the test environment.

And have a parameter resource:

[validatingadmissionpolicy/replicalimit-param-prod.yaml](#)

```
apiVersion: rules.example.com/v1
kind: ReplicaLimit
metadata:
 name: "replica-limit-prod.example.com"
maxReplicas: 100
```

For each admission request, the API server evaluates CEL expressions of each (policy, binding, param) combination that match the request. For a request to be admitted it must pass **all** evaluations.

If multiple bindings match the request, the policy will be evaluated for each, and they must all pass evaluation for the policy to be considered passed.

If multiple parameters match a single binding, the policy rules will be evaluated for each param, and they too must all pass for the binding to be considered passed. Bindings can have overlapping match criteria. The policy is evaluated for each matching binding-parameter combination. A policy may even be evaluated multiple times if multiple bindings match it, or a single binding that matches multiple parameters.

The params object representing a parameter resource will not be set if a parameter resource has not been bound, so for policies requiring a parameter resource, it can be useful to add a check to ensure one has been bound. A parameter resource will not be bound and params will be null if paramKind of the policy, or paramRef of the binding are not specified.

For the use cases require parameter configuration, we recommend to add a param check in spec.validations[0].expression:

```
- expression: "params != null"
 message: "params missing but required to bind to this policy"
```

## Optional parameters

It can be convenient to be able to have optional parameters as part of a parameter resource, and only validate them if present. CEL provides has(), which checks if the key passed to it exists. CEL also implements Boolean short-circuiting. If the first half of a logical OR evaluates to true, it won't evaluate the other half (since the result of the entire OR will be true regardless).

Combining the two, we can provide a way to validate optional parameters:

```
!has(params.optionalNumber) || (params.optionalNumber >= 5 && params.optionalNumber <= 10)
```

Here, we first check that the optional parameter is present with `!has(params.optionalNumber)`.

- If `optionalNumber` hasn't been defined, then the expression short-circuits since `!has(params.optionalNumber)` will evaluate to true.
- If `optionalNumber` has been defined, then the latter half of the CEL expression will be evaluated, and `optionalNumber` will be checked to ensure that it contains a value between 5 and 10 inclusive.

## Per-namespace Parameters

As the author of a `ValidatingAdmissionPolicy` and its `ValidatingAdmissionPolicyBinding`, you can choose to specify cluster-wide, or per-namespace parameters. If you specify a namespace for the binding's `paramRef`, the control plane only searches for parameters in that namespace.

However, if `namespace` is not specified in the `ValidatingAdmissionPolicyBinding`, the API server can search for relevant parameters in the namespace that a request is against. For example, if you make a request to modify a `ConfigMap` in the default namespace and there is a relevant `ValidatingAdmissionPolicyBinding` with no namespace set, then the API server looks for a parameter object in default. This design enables policy configuration that depends on the namespace of the resource being manipulated, for more fine-tuned control.

## Parameter selector

In addition to specify a parameter in a binding by name, you may choose instead to specify label selector, such that all resources of the policy's `paramKind`, and the `param`'s namespace (if applicable) that match the label selector are selected for evaluation. See [selector](#) for more information on how label selectors match resources.

If multiple parameters are found to meet the condition, the policy's rules are evaluated for each parameter found and the results will be ANDed together.

If `namespace` is provided, only objects of the `paramKind` in the provided namespace are eligible for selection. Otherwise, when `namespace` is empty and `paramKind` is namespace-scoped, the namespace used in the request being admitted will be used.

## Authorization checks

We introduced the authorization check for parameter resources. User is expected to have read access to the resources referenced by `paramKind` in `ValidatingAdmissionPolicy` and `paramRef` in `ValidatingAdmissionPolicyBinding`.

Note that if a resource in `paramKind` fails resolving via the restmapper, read access to all resources of groups is required.

## Failure Policy

`failurePolicy` defines how mis-configurations and CEL expressions evaluating to error from the admission policy are handled. Allowed values are Ignore or Fail.

- Ignore means that an error calling the `ValidatingAdmissionPolicy` is ignored and the API request is allowed to continue.
- Fail means that an error calling the `ValidatingAdmissionPolicy` causes the admission to fail and the API request to be rejected.

Note that the `failurePolicy` is defined inside `ValidatingAdmissionPolicy`:

[validatingadmissionpolicy/failure-policy-ignore.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
spec:
...
failurePolicy: Ignore # The default is "Fail"
validations:
- expression: "object.spec.xyz == params.x"
```

## Validation Expression

`spec.validations[i].expression` represents the expression which will be evaluated by CEL. To learn more, see the [CEL language specification](#) CEL expressions have access to the contents of the Admission request/response, organized into CEL variables as well as some other useful variables:

- 'object' - The object from the incoming request. The value is null for DELETE requests.
- 'oldObject' - The existing object. The value is null for CREATE requests.
- 'request' - Attributes of the [admission request](#).
- 'params' - Parameter resource referred to by the policy binding being evaluated. The value is null if `ParamKind` is not specified.
- `namespaceObject` - The namespace, as a Kubernetes resource, that the incoming object belongs to. The value is null if the incoming object is cluster-scoped.
- `authorizer` - A CEL Authorizer. May be used to perform authorization checks for the principal (authenticated user) of the request. See [Authz](#) in the Kubernetes CEL library documentation for more details.
- `authorizer.requestResource` - A shortcut for an authorization check configured with the request resource (group, resource, (subresource), namespace, name).

The `apiVersion`, `kind`, `metadata.name` and `metadata.generateName` are always accessible from the root of the object. No other metadata properties are accessible.

Equality on arrays with list type of 'set' or 'map' ignores element order, i.e. `[1, 2] == [2, 1]`. Concatenation on arrays with `x-kubernetes-list-type` use the semantics of the list type:

- 'set': `X + Y` performs a union where the array positions of all elements in `X` are preserved and non-intersecting elements in `Y` are appended, retaining their partial order.
- 'map': `X + Y` performs a merge where the array positions of all keys in `X` are preserved but the values are overwritten by values in `Y` when the key sets of `X` and `Y` intersect. Elements in `Y` with non-intersecting keys are appended, retaining their partial order.

## Validation expression examples

| Expression                                                                                                  | Purpose                                                                                        |
|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|
| <code>object.minReplicas &lt;= object.replicas &amp;&amp; object.replicas &lt;= object.maxReplicas</code>   | Validate that the three fields defining replicas are ordered appropriately                     |
| <code>'Available' in object.stateCounts</code>                                                              | Validate that an entry with the 'Available' key exists in a map                                |
| <code>(size(object.list1) == 0) != (size(object.list2) == 0)</code>                                         | Validate that one of two lists is non-empty, but not both                                      |
| <code>!('MY_KEY' in object.map1)    object['MY_KEY'].matches('^[a-zA-Z]*\$')</code>                         | Validate the value of a map for a specific key, if it is in the map                            |
| <code>object.envvars.filter(e, e.name == 'MY_ENV').all(e, e.value.matches('^[a-zA-Z]*\$'))</code>           | Validate the 'value' field of a listMap entry where key field 'name' is 'MY_ENV'               |
| <code>has(object.expired) &amp;&amp; object.created + object.ttl &lt; object.expired</code>                 | Validate that 'expired' date is after a 'create' date plus a 'ttl' duration                    |
| <code>object.health.startsWith('ok')</code>                                                                 | Validate a 'health' string field has the prefix 'ok'                                           |
| <code>object.widgets.exists(w, w.key == 'x' &amp;&amp; w.foo &lt; 10)</code>                                | Validate that the 'foo' property of a listMap item with a key 'x' is less than 10              |
| <code>type(object) == string ? object == '100%' : object == 1000</code>                                     | Validate an int-or-string field for both the int and string cases                              |
| <code>object.metadata.name.startsWith(object.prefix)</code>                                                 | Validate that an object's name has the prefix of another field value                           |
| <code>object.set1.all(e, !(e in object.set2))</code>                                                        | Validate that two listSets are disjoint                                                        |
| <code>size(object.names) == size(object.details) &amp;&amp; object.names.all(n, n in object.details)</code> | Validate the 'details' map is keyed by the items in the 'names' listSet                        |
| <code>size(object.clusters.filter(c, c.name == object.primary)) == 1</code>                                 | Validate that the 'primary' property has one and only one occurrence in the 'clusters' listMap |

Read [Supported evaluation on CEL](#) for more information about CEL rules.

`spec.validation[i].reason` represents a machine-readable description of why this validation failed. If this is the first validation in the list to fail, this reason, as well as the corresponding HTTP response code, are used in the HTTP response to the client. The currently supported reasons are: Unauthorized, Forbidden, Invalid, RequestEntityTooLarge. If not set, `StatusReasonInvalid` is used in the response to the client.

## Matching requests: matchConditions

You can define *match conditions* for a `ValidatingAdmissionPolicy` if you need fine-grained request filtering. These conditions are useful if you find that match rules, objectSelectors and namespaceSelectors still doesn't provide the filtering you want. Match conditions are [CEL expressions](#). All match conditions must evaluate to true for the resource to be evaluated.

Here is an example illustrating a few different uses for match conditions:

[access/validating-admission-policy-match-conditions.yaml](#)

```

apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "demo-policy.example.com"
spec:
 failurePolicy: Fail
 matchConstraints:
 resourceRules:
 - apiGroups: ["*"]
 apiVersions: ["*"]
 operations: ["CREATE", "UPDATE"]
 resources: ["*"]
 matchConditions:
 - name: 'exclude-leases' # Each match condition must have a unique name
 expression: '!(request.resource.group == "coordination.k8s.io" && request.resource.resource
 == "leases")' # Match non-lease resources.
 - name: 'exclude-kubelet-requests'
 expression: '!("system:nodes" in request.userInfo.groups)' # Match requests made by non-
 node users.
 - name: 'rbac' # Skip RBAC requests.
 expression: 'request.resource.group != "rbac.authorization.k8s.io"'
 validations:
 - expression: "!object.metadata.name.contains('demo') || object.metadata.namespace ==
 'demo'"

```

Match conditions have access to the same CEL variables as validation expressions.

In the event of an error evaluating a match condition the policy is not evaluated. Whether to reject the request is determined as follows:

1. If **any** match condition evaluated to false (regardless of other errors), the API server skips the policy.
2. Otherwise:
  - for [failurePolicy: Fail](#), reject the request (without evaluating the policy).
  - for [failurePolicy: Ignore](#), proceed with the request but skip the policy.

## Audit annotations

auditAnnotations may be used to include audit annotations in the audit event of the API request.

For example, here is an admission policy with an audit annotation:

[access/validating-admission-policy-audit-annotation.yaml](#)

```

apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "demo-policy.example.com"
spec:
 failurePolicy: Fail
 matchConstraints:

```

```

resourceRules:
- apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments"]
validations:
- expression: "object.spec.replicas > 50"
 messageExpression: "Deployment spec.replicas set to ' + string(object.spec.replicas)"
auditAnnotations:
- key: "high-replica-count"
 valueExpression: "Deployment spec.replicas set to ' + string(object.spec.replicas)"

```

When an API request is validated with this admission policy, the resulting audit event will look like:

```

the audit event recorded
{
 "kind": "Event",
 "apiVersion": "audit.k8s.io/v1",
 "annotations": {
 "demo-policy.example.com/high-replica-count": "Deployment spec.replicas set to 128"
 # other annotations
 ...
 }
 # other fields
 ...
}

```

In this example the annotation will only be included if the `spec.replicas` of the Deployment is more than 50, otherwise the CEL expression evaluates to null and the annotation will not be included.

Note that audit annotation keys are prefixed by the name of the ValidatingAdmissionWebhook and a /. If another admission controller, such as an admission webhook, uses the exact same audit annotation key, the value of the first admission controller to include the audit annotation will be included in the audit event and all other values will be ignored.

## Message expression

To return a more friendly message when the policy rejects a request, we can use a CEL expression to composite a message with `spec.validations[i].messageExpression`. Similar to the validation expression, a message expression has access to `object`, `oldObject`, `request`, `params`, and `namespaceObject`. Unlike validations, message expression must evaluate to a string.

For example, to better inform the user of the reason of denial when the policy refers to a parameter, we can have the following validation:

[access/deployment-replicas-policy.yaml](#)

```

apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "deploy-replica-policy.example.com"

```

```
spec:
 paramKind:
 apiVersion: rules.example.com/v1
 kind: ReplicaLimit
 matchConstraints:
 resourceRules:
 - apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments"]
 validations:
 - expression: "object.spec.replicas <= params.maxReplicas"
 messageExpression: "'object.spec.replicas must be no greater than ' +
string(params.maxReplicas)"
 reason: Invalid
```

After creating a params object that limits the replicas to 3 and setting up the binding, when we try to create a deployment with 5 replicas, we will receive the following message.

```
$ kubectl create deploy --image=nginx nginx --replicas=5
error: failed to create deployment: deployments.apps "nginx" is forbidden:
ValidatingAdmissionPolicy 'deploy-replica-policy.example.com' with binding 'demo-binding-
test.example.com' denied request: object.spec.replicas must be no greater than 3
```

This is more informative than a static message of "too many replicas".

The message expression takes precedence over the static message defined in `spec.validations[i].message` if both are defined. However, if the message expression fails to evaluate, the static message will be used instead. Additionally, if the message expression evaluates to a multi-line string, the evaluation result will be discarded and the static message will be used if present. Note that static message is validated against multi-line strings.

## Type checking

When a policy definition is created or updated, the validation process parses the expressions it contains and reports any syntax errors, rejecting the definition if any errors are found. Afterward, the referred variables are checked for type errors, including missing fields and type confusion, against the matched types of `spec.matchConstraints`. The result of type checking can be retrieved from `status.typeChecking`. The presence of `status.typeChecking` indicates the completion of type checking, and an empty `status.typeChecking` means that no errors were detected.

For example, given the following policy definition:

[validatingadmissionpolicy/typechecking.yaml](#)

```
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "deploy-replica-policy.example.com"
spec:
 matchConstraints:
```

```

resourceRules:
- apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments"]
validations:
- expression: "object.replicas > 1" # should be "object.spec.replicas > 1"
 message: "must be replicated"
 reason: Invalid

```

The status will yield the following information:

```

status:
 typeChecking:
 expressionWarnings:
 - fieldRef: spec.validations[0].expression
 warning: |-
 apps/v1, Kind=Deployment: ERROR: <input>:1:7: undefined field 'replicas'
 | object.replicas > 1
 |^

```

If multiple resources are matched in `spec.matchConstraints`, all of matched resources will be checked against. For example, the following policy definition

[validatingadmissionpolicy/typechecking-multiple-match.yaml](#)

```

apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "replica-policy.example.com"
spec:
 matchConstraints:
 resourceRules:
 - apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments", "replicasets"]
 validations:
 - expression: "object.replicas > 1" # should be "object.spec.replicas > 1"
 message: "must be replicated"
 reason: Invalid

```

will have multiple types and type checking result of each type in the warning message.

```

status:
 typeChecking:
 expressionWarnings:
 - fieldRef: spec.validations[0].expression
 warning: |-
 apps/v1, Kind=Deployment: ERROR: <input>:1:7: undefined field 'replicas'
 | object.replicas > 1
 |^
 apps/v1, Kind=ReplicaSet: ERROR: <input>:1:7: undefined field 'replicas'

```

```
| object.replicas > 1
|^
```

Type Checking has the following limitation:

- No wildcard matching. If `spec.matchConstraints.resourceRules` contains "\*" in any of `apiGroups`, `apiVersions` or `resources`, the types that "\*" matches will not be checked.
- The number of matched types is limited to 10. This is to prevent a policy that manually specifying too many types. to consume excessive computing resources. In the order of ascending group, version, and then resource, 11th combination and beyond are ignored.
- Type Checking does not affect the policy behavior in any way. Even if the type checking detects errors, the policy will continue to evaluate. If errors do occur during evaluate, the failure policy will decide its outcome.
- Type Checking does not apply to CRDs, including matched CRD types and reference of `paramKind`. The support for CRDs will come in future release.

## Variable composition

If an expression grows too complicated, or part of the expression is reusable and computationally expensive to evaluate, you can extract some part of the expressions into variables. A variable is a named expression that can be referred later in variables in other expressions.

```
spec:
 variables:
 - name: foo
 expression: "'foo' in object.spec.metadata.labels ? object.spec.metadata.labels['foo'] : 'default'"
 validations:
 - expression: variables.foo == 'bar'
```

A variable is lazily evaluated when it is first referred. Any error that occurs during the evaluation will be reported during the evaluation of the referring expression. Both the result and potential error are memorized and count only once towards the runtime cost.

The order of variables are important because a variable can refer to other variables that are defined before it. This ordering prevents circular references.

The following is a more complex example of enforcing that image repo names match the environment defined in its namespace.

[access/image-matches-namespace-environment.policy.yaml](#)

```
This policy enforces that all containers of a deployment has the image repo match the
environment label of its namespace.
Except for "exempt" deployments, or any containers that do not belong to the "example.com"
organization (e.g. common sidecars).
For example, if the namespace has a label of {"environment": "staging"}, all container images
must be either staging.example.com/*
or do not contain "example.com" at all, unless the deployment has {"exempt": "true"} label.
apiVersion: admissionregistration.k8s.io/v1
kind: ValidatingAdmissionPolicy
metadata:
 name: "image-matches-namespace-environment.policy.example.com"
spec:
```

```

failurePolicy: Fail
matchConstraints:
 resourceRules:
 - apiGroups: ["apps"]
 apiVersions: ["v1"]
 operations: ["CREATE", "UPDATE"]
 resources: ["deployments"]
 variables:
 - name: environment
 expression: "'environment' in namespaceObject.metadata.labels ?
namespaceObject.metadata.labels['environment'] : 'prod'"
 - name: exempt
 expression: "'exempt' in object.metadata.labels && object.metadata.labels['exempt'] == 'true'"
 - name: containers
 expression: "object.spec.template.spec.containers"
 - name: containersToCheck
 expression: "variables.containers.filter(c, c.image.contains('example.com/'))"
 validations:
 - expression: "variables.exempt || variables.containersToCheck.all(c,
c.image.startsWith(variables.environment + ':'))"
 messageExpression: "'only ' + variables.environment + ' images are allowed in namespace ' +
namespaceObject.metadata.name"

```

With the policy bound to the namespace default, which is labeled `environment: prod`, the following attempt to create a deployment would be rejected.

```
kubectl create deploy --image=dev.example.com/nginx invalid
```

The error message is similar to this.

```

error: failed to create deployment: deployments.apps "invalid" is forbidden:
ValidatingAdmissionPolicy 'image-matches-namespace-environment.policy.example.com' with
binding 'demo-binding-test.example.com' denied request: only prod images are allowed in
namespace default

```

## Well-Known Labels, Annotations and Taints

Kubernetes reserves all labels and annotations in the `kubernetes.io` and `k8s.io` namespaces.

This document serves both as a reference to the values and as a coordination point for assigning values.

### Labels, annotations and taints used on API objects

#### `apf.kubernetes.io/autoupdate-spec`

Type: Annotation

Example: `apf.kubernetes.io/autoupdate-spec: "true"`

Used on: [FlowSchema and PriorityLevelConfiguration Objects](#)

If this annotation is set to true on a FlowSchema or PriorityLevelConfiguration, the spec for that object is managed by the kube-apiserver. If the API server does not recognize an APF object, and you annotate it for automatic update, the API server deletes the entire object. Otherwise, the API server does not manage the object spec. For more details, read [Maintenance of the Mandatory and Suggested Configuration Objects](#).

## **app.kubernetes.io/component**

Type: Label

Example: `app.kubernetes.io/component: "database"`

Used on: All Objects (typically used on [workload resources](#)).

The component within the application architecture.

One of the [recommended labels](#).

## **app.kubernetes.io/created-by (deprecated)**

Type: Label

Example: `app.kubernetes.io/created-by: "controller-manager"`

Used on: All Objects (typically used on [workload resources](#)).

The controller/user who created this resource.

### **Note:**

Starting from v1.9, this label is deprecated.

## **app.kubernetes.io/instance**

Type: Label

Example: `app.kubernetes.io/instance: "mysql-abcxyz"`

Used on: All Objects (typically used on [workload resources](#)).

A unique name identifying the instance of an application. To assign a non-unique name, use [app.kubernetes.io/name](#).

One of the [recommended labels](#).

## **app.kubernetes.io/managed-by**

Type: Label

Example: `app.kubernetes.io/managed-by: "helm"`

Used on: All Objects (typically used on [workload resources](#)).

The tool being used to manage the operation of an application.

One of the [recommended labels](#).

## **app.kubernetes.io/name**

Type: Label

Example: `app.kubernetes.io/name: "mysql"`

Used on: All Objects (typically used on [workload resources](#)).

The name of the application.

One of the [recommended labels](#).

## **app.kubernetes.io/part-of**

Type: Label

Example: `app.kubernetes.io/part-of: "wordpress"`

Used on: All Objects (typically used on [workload resources](#)).

The name of a higher-level application this object is part of.

One of the [recommended labels](#).

## **app.kubernetes.io/version**

Type: Label

Example: `app.kubernetes.io/version: "5.7.21"`

Used on: All Objects (typically used on [workload resources](#)).

The current version of the application.

Common forms of values include:

- [semantic version](#)
- the Git [revision hash](#) for the source code.

One of the [recommended labels](#).

## **applyset.kubernetes.io/additional-namespaces (alpha)**

Type: Annotation

Example: `applyset.kubernetes.io/additional-namespaces: "namespace1,namespace2"`

Used on: Objects being used as ApplySet parents.

Use of this annotation is Alpha. For Kubernetes version 1.30, you can use this annotation on Secrets, ConfigMaps, or custom resources if the [CustomResourceDefinition](#) defining them has the `applyset.kubernetes.io/is-parent-type` label.

Part of the specification used to implement [ApplySet-based pruning in kubectl](#). This annotation is applied to the parent object used to track an ApplySet to extend the scope of the ApplySet beyond the parent object's own namespace (if any). The value is a comma-separated list of the names of namespaces other than the parent's namespace in which objects are found.

## **applyset.kubernetes.io/contains-group-resources (alpha)**

Type: Annotation

Example: `applyset.kubernetes.io/contains-group-resources: "certificates.cert-manager.io,configmaps,deployments.apps,secrets,services"`

Used on: Objects being used as ApplySet parents.

Use of this annotation is Alpha. For Kubernetes version 1.30, you can use this annotation on Secrets, ConfigMaps, or custom resources if the CustomResourceDefinition defining them has the `applyset.kubernetes.io/is-parent-type` label.

Part of the specification used to implement [ApplySet-based pruning in kubectl](#). This annotation is applied to the parent object used to track an ApplySet to optimize listing of ApplySet member objects. It is optional in the ApplySet specification, as tools can perform discovery or use a different optimization. However, as of Kubernetes version 1.30, it is required by kubectl. When present, the value of this annotation must be a comma separated list of the group-kinds, in the fully-qualified name format, i.e. `<resource>.<group>`.

## **applyset.kubernetes.io/id (alpha)**

Type: Label

Example: `applyset.kubernetes.io/id: "applyset-0eFHV8ySq7XoShsGvyWFQD3s96yqwHmzc4e0HR1dsY-v1"`

Used on: Objects being used as ApplySet parents.

Use of this label is Alpha. For Kubernetes version 1.30, you can use this label on Secrets, ConfigMaps, or custom resources if the CustomResourceDefinition defining them has the `applyset.kubernetes.io/is-parent-type` label.

Part of the specification used to implement [ApplySet-based pruning in kubectl](#). This label is what makes an object an ApplySet parent object. Its value is the unique ID of the ApplySet, which is derived from the identity of the parent object itself. This ID **must** be the base64 encoding (using the URL safe encoding of RFC4648) of the hash of the group-kind-name-namespace of the object it is on, in the form:

`<base64(sha256(<name>.<namespace>.<kind>.<group>))>`. There is no relation between the value of this label and object UID.

## **applyset.kubernetes.io/is-parent-type (alpha)**

Type: Label

Example: `applyset.kubernetes.io/is-parent-type: "true"`

Used on: Custom Resource Definition (CRD)

Use of this label is Alpha. Part of the specification used to implement [ApplySet-based pruning in kubectl](#). You can set this label on a CustomResourceDefinition (CRD) to identify the custom resource type it defines (not the CRD itself) as an allowed parent for an ApplySet. The only permitted value for this label is "true"; if you want to mark a CRD as not being a valid parent for ApplySets, omit this label.

## **applyset.kubernetes.io/part-of (alpha)**

Type: Label

Example: `applyset.kubernetes.io/part-of: "applyset-0eFHV8ySqP7XoShsGvyWFQD3s96yqwHmzc4e0HR1dsY-v1"`

Used on: All objects.

Use of this label is Alpha. Part of the specification used to implement [ApplySet-based pruning in kubectl](#). This label is what makes an object a member of an ApplySet. The value of the label **must** match the value of the `applyset.kubernetes.io/id` label on the parent object.

## **applyset.kubernetes.io/tooling (alpha)**

Type: Annotation

Example: `applyset.kubernetes.io/tooling: "kubectl/v1.30"`

Used on: Objects being used as ApplySet parents.

Use of this annotation is Alpha. For Kubernetes version 1.30, you can use this annotation on Secrets, ConfigMaps, or custom resources if the CustomResourceDefinition defining them has the `applyset.kubernetes.io/is-parent-type` label.

Part of the specification used to implement [ApplySet-based pruning in kubectl](#). This annotation is applied to the parent object used to track an ApplySet to indicate which tooling manages that ApplySet. Tooling should refuse to mutate ApplySets belonging to other tools. The value must be in the format `<toolname>/<semver>`.

## **apps.kubernetes.io/pod-index (beta)**

Type: Label

Example: `apps.kubernetes.io/pod-index: "0"`

Used on: Pod

When a StatefulSet controller creates a Pod for the StatefulSet, it sets this label on that Pod. The value of the label is the ordinal index of the pod being created.

See [Pod Index Label](#) in the StatefulSet topic for more details. Note the [PodIndexLabel](#) feature gate must be enabled for this label to be added to pods.

## **cluster-autoscaler.kubernetes.io/safe-to-evict**

Type: Annotation

Example: `cluster-autoscaler.kubernetes.io/safe-to-evict: "true"`

Used on: Pod

When this annotation is set to "true", the cluster autoscaler is allowed to evict a Pod even if other rules would normally prevent that. The cluster autoscaler never evicts Pods that have this annotation explicitly set to "false"; you could set that on an important Pod that you want to keep running. If this annotation is not set then the cluster autoscaler follows its Pod-level behavior.

## **config.kubernetes.io/local-config**

Type: Annotation

Example: `config.kubernetes.io/local-config: "true"`

Used on: All objects

This annotation is used in manifests to mark an object as local configuration that should not be submitted to the Kubernetes API.

A value of "true" for this annotation declares that the object is only consumed by client-side tooling and should not be submitted to the API server.

A value of "false" can be used to declare that the object should be submitted to the API server even when it would otherwise be assumed to be local.

This annotation is part of the Kubernetes Resource Model (KRM) Functions Specification, which is used by Kustomize and similar third-party tools. For example, Kustomize removes objects with this annotation from its final build output.

## **container.apparmor.security.beta.kubernetes.io/\* (deprecated)**

Type: Annotation

Example: `container.apparmor.security.beta.kubernetes.io/my-container: my-custom-profile`

Used on: Pods

This annotation allows you to specify the AppArmor security profile for a container within a Kubernetes pod. As of Kubernetes v1.30, this should be set with the `appArmorProfile` field instead. To learn more, see the [AppArmor](#) tutorial. The tutorial illustrates using AppArmor to restrict a container's abilities and access.

The profile specified dictates the set of rules and restrictions that the containerized process must adhere to. This helps enforce security policies and isolation for your containers.

## **internal.config.kubernetes.io/\* (reserved prefix)**

Type: Annotation

Used on: All objects

This prefix is reserved for internal use by tools that act as orchestrators in accordance with the Kubernetes Resource Model (KRM) Functions Specification. Annotations with this prefix are internal to the orchestration process and are not persisted to the manifests on the filesystem. In other words, the orchestrator tool should set these annotations when reading files from the local filesystem and remove them when writing the output of functions back to the filesystem.

A KRM function **must not** modify annotations with this prefix, unless otherwise specified for a given annotation. This enables orchestrator tools to add additional internal annotations, without requiring changes to existing functions.

## **internal.config.kubernetes.io/path**

Type: Annotation

Example: `internal.config.kubernetes.io/path: "relative/file/path.yaml"`

Used on: All objects

This annotation records the slash-delimited, OS-agnostic, relative path to the manifest file the object was loaded from. The path is relative to a fixed location on the filesystem, determined by the orchestrator tool.

This annotation is part of the Kubernetes Resource Model (KRM) Functions Specification, which is used by Kustomize and similar third-party tools.

A KRM Function **should not** modify this annotation on input objects unless it is modifying the referenced files. A KRM Function **may** include this annotation on objects it generates.

## **internal.config.kubernetes.io/index**

Type: Annotation

Example: `internal.config.kubernetes.io/index: "2"`

Used on: All objects

This annotation records the zero-indexed position of the YAML document that contains the object within the manifest file the object was loaded from. Note that YAML documents are separated by three dashes (---) and can each contain one object. When this annotation is not specified, a value of 0 is implied.

This annotation is part of the Kubernetes Resource Model (KRM) Functions Specification, which is used by Kustomize and similar third-party tools.

A KRM Function **should not** modify this annotation on input objects unless it is modifying the referenced files. A KRM Function **may** include this annotation on objects it generates.

## **kubernetes.io/arch**

Type: Label

Example: `kubernetes.io/arch: "amd64"`

Used on: Node

The Kubelet populates this with `runtime.GOARCH` as defined by Go. This can be handy if you are mixing ARM and x86 nodes.

## **kubernetes.io/os**

Type: Label

Example: `kubernetes.io/os: "linux"`

Used on: Node, Pod

For nodes, the kubelet populates this with `runtime.GOOS` as defined by Go. This can be handy if you are mixing operating systems in your cluster (for example: mixing Linux and Windows nodes).

You can also set this label on a Pod. Kubernetes allows you to set any value for this label; if you use this label, you should nevertheless set it to the Go `runtime.GOOS` string for the operating system that this Pod actually works with.

When the `kubernetes.io/os` label value for a Pod does not match the label value on a Node, the kubelet on the node will not admit the Pod. However, this is not taken into account by the kube-scheduler. Alternatively, the kubelet refuses to run a Pod where you have specified a Pod OS, if this isn't the same as the operating system for the node where that kubelet is running. Just look for [Pods OS](#) for more details.

## **kubernetes.io/metadata.name**

Type: Label

Example: `kubernetes.io/metadata.name: "mynamespace"`

Used on: Namespaces

The Kubernetes API server (part of the [control plane](#)) sets this label on all namespaces. The label value is set to the name of the namespace. You can't change this label's value.

This is useful if you want to target a specific namespace with a label [selector](#).

## **kubernetes.io/limit-ranger**

Type: Annotation

Example: `kubernetes.io/limit-ranger: "LimitRanger plugin set: cpu, memory request for container nginx; cpu, memory limit for container nginx"`

Used on: Pod

Kubernetes by default doesn't provide any resource limit, that means unless you explicitly define limits, your container can consume unlimited CPU and memory. You can define a default request or default limit for pods. You do this by creating a `LimitRange` in the relevant namespace. Pods deployed after you define a `LimitRange` will have these limits applied to them.

The annotation `kubernetes.io/limit-ranger` records that resource defaults were specified for the Pod, and they were applied successfully. For more details, read about [LimitRanges](#).

## **kubernetes.io/config.hash**

Type: Annotation

Example: `kubernetes.io/config.hash: "df7cc47f8477b6b1226d7d23a904867b"`

Used on: Pod

When the kubelet creates a static Pod based on a given manifest, it attaches this annotation to the static Pod. The value of the annotation is the UID of the Pod. Note that the kubelet also sets the `.spec.nodeName` to the current node name as if the Pod was scheduled to the node.

## **kubernetes.io/config.mirror**

Type: Annotation

Example: `kubernetes.io/config.mirror: "df7cc47f8477b6b1226d7d23a904867b"`

Used on: Pod

For a static Pod created by the kubelet on a node, a [mirror Pod](#) is created on the API server. The kubelet adds an annotation to indicate that this Pod is actually a mirror Pod. The annotation value is copied from the [kubernetes.io/config.hash](#) annotation, which is the UID of the Pod.

When updating a Pod with this annotation set, the annotation cannot be changed or removed. If a Pod doesn't have this annotation, it cannot be added during a Pod update.

## **kubernetes.io/config.source**

Type: Annotation

Example: `kubernetes.io/config.source: "file"`

Used on: Pod

This annotation is added by the kubelet to indicate where the Pod comes from. For static Pods, the annotation value could be one of `file` or `http` depending on where the Pod manifest is located. For a Pod created on the API server and then scheduled to the current node, the annotation value is `api`.

## **kubernetes.io/config.seen**

Type: Annotation

Example: `kubernetes.io/config.seen: "2023-10-27T04:04:56.011314488Z"`

Used on: Pod

When the kubelet sees a Pod for the first time, it may add this annotation to the Pod with a value of current timestamp in the RFC3339 format.

## **addonmanager.kubernetes.io/mode**

Type: Label

Example: `addonmanager.kubernetes.io/mode: "Reconcile"`

Used on: All objects

To specify how an add-on should be managed, you can use the `addonmanager.kubernetes.io/mode` label. This label can have one of three values: `Reconcile`, `EnsureExists`, or `Ignore`.

- `Reconcile`: Addon resources will be periodically reconciled with the expected state. If there are any differences, the add-on manager will recreate, reconfigure or delete the resources as needed. This is the default mode if no label is specified.
- `EnsureExists`: Addon resources will be checked for existence only but will not be modified after creation. The add-on manager will create or re-create the resources when there is no instance of the resource with that name.
- `Ignore`: Addon resources will be ignored. This mode is useful for add-ons that are not compatible with the add-on manager or that are managed by another controller.

For more details, see [Add-on manager](#).

## **beta.kubernetes.io/arch (deprecated)**

Type: Label

This label has been deprecated. Please use [kubernetes.io/arch](#) instead.

## **beta.kubernetes.io/os (deprecated)**

Type: Label

This label has been deprecated. Please use [kubernetes.io/os](#) instead.

## **kube-aggregator.kubernetes.io/automanaged**

Type: Label

Example: `kube-aggregator.kubernetes.io/automanaged: "onstart"`

Used on: APIService

The kube-apiserver sets this label on any APIService object that the API server has created automatically. The label marks how the control plane should manage that APIService. You should not add, modify, or remove this label by yourself.

### **Note:**

Automanaged APIService objects are deleted by kube-apiserver when it has no built-in or custom resource API corresponding to the API group/version of the APIService.

There are two possible values:

- `onstart`: The APIService should be reconciled when an API server starts up, but not otherwise.
- `true`: The API server should reconcile this APIService continuously.

## **service.alpha.kubernetes.io/tolerate-unready-endpoints (deprecated)**

Type: Annotation

Used on: StatefulSet

This annotation on a Service denotes if the Endpoints controller should go ahead and create Endpoints for unready Pods. Endpoints of these Services retain their DNS records and continue receiving traffic for the Service from the moment the kubelet starts all containers in the pod and marks it *Running*, til the kubelet stops all containers and deletes the pod from the API server.

## **kubernetes.io/hostname**

Type: Label

Example: `kubernetes.io/hostname: "ip-172-20-114-199.ec2.internal"`

Used on: Node

The Kubelet populates this label with the hostname of the node. Note that the hostname can be changed from the "actual" hostname by passing the `--hostname-override` flag to the kubelet.

This label is also used as part of the topology hierarchy. See [topology.kubernetes.io/zone](https://kubernetes.io/docs/concepts/topology/topology-hierarchy/) for more information.

## **kubernetes.io/change-cause**

Type: Annotation

Example: `kubernetes.io/change-cause: "kubectl edit --record deployment foo"`

Used on: All Objects

This annotation is a best guess at why something was changed.

It is populated when adding `--record` to a `kubectl` command that may change an object.

## **kubernetes.io/description**

Type: Annotation

Example: `kubernetes.io/description: "Description of K8s object."`

Used on: All Objects

This annotation is used for describing specific behaviour of given object.

## kubernetes.io/enforce-mountable-secrets

Type: Annotation

Example: `kubernetes.io/enforce-mountable-secrets: "true"`

Used on: ServiceAccount

The value for this annotation must be **true** to take effect. When you set this annotation to "true", Kubernetes enforces the following rules for Pods running as this ServiceAccount:

1. Secrets mounted as volumes must be listed in the ServiceAccount's `secrets` field.
2. Secrets referenced in `envFrom` for containers (including sidecar containers and init containers) must also be listed in the ServiceAccount's `secrets` field. If any container in a Pod references a Secret not listed in the ServiceAccount's `secrets` field (and even if the reference is marked as optional), then the Pod will fail to start, and an error indicating the non-compliant secret reference will be generated.
3. Secrets referenced in a Pod's `imagePullSecrets` must be present in the ServiceAccount's `imagePullSecrets` field, the Pod will fail to start, and an error indicating the non-compliant image pull secret reference will be generated.

When you create or update a Pod, these rules are checked. If a Pod doesn't follow them, it won't start and you'll see an error message. If a Pod is already running and you change the `kubernetes.io/enforce-mountable-secrets` annotation to true, or you edit the associated ServiceAccount to remove the reference to a Secret that the Pod is already using, the Pod continues to run.

## node.kubernetes.io/exclude-from-external-load-balancers

Type: Label

Example: `node.kubernetes.io/exclude-from-external-load-balancers`

Used on: Node

Kubernetes automatically enables the `ServiceNodeExclusion` feature gate on the clusters it creates. With this feature gate enabled on a cluster, you can add labels to particular worker nodes to exclude them from the list of backend servers. The following command can be used to exclude a worker node from the list of backend servers in a backend set:

```
kubectll label nodes <node-name> node.kubernetes.io/exclude-from-external-load-balancers=true
```

## controller.kubernetes.io/pod-deletion-cost

Type: Annotation

Example: `controller.kubernetes.io/pod-deletion-cost: "10"`

Used on: Pod

This annotation is used to set [Pod Deletion Cost](#) which allows users to influence ReplicaSet downscaling order. The annotation value parses into an `int32` type.

## **cluster-autoscaler.kubernetes.io/enable-ds-eviction**

Type: Annotation

Example: cluster-autoscaler.kubernetes.io/enable-ds-eviction: "true"

Used on: Pod

This annotation controls whether a DaemonSet pod should be evicted by a ClusterAutoscaler. This annotation needs to be specified on DaemonSet pods in a DaemonSet manifest. When this annotation is set to "true", the ClusterAutoscaler is allowed to evict a DaemonSet Pod, even if other rules would normally prevent that. To disallow the ClusterAutoscaler from evicting DaemonSet pods, you can set this annotation to "false" for important DaemonSet pods. If this annotation is not set, then the ClusterAutoscaler follows its overall behavior (i.e evict the DaemonSets based on its configuration).

### **Note:**

This annotation only impacts DaemonSet Pods.

## **kubernetes.io/ingress-bandwidth**

Type: Annotation

Example: kubernetes.io/ingress-bandwidth: 10M

Used on: Pod

You can apply quality-of-service traffic shaping to a pod and effectively limit its available bandwidth. Ingress traffic to a Pod is handled by shaping queued packets to effectively handle data. To limit the bandwidth on a Pod, write an object definition JSON file and specify the data traffic speed using kubernetes.io/ingress-bandwidth annotation. The unit used for specifying ingress rate is bits per second, as a [Quantity](#). For example, 10M means 10 megabits per second.

### **Note:**

Ingress traffic shaping annotation is an experimental feature. If you want to enable traffic shaping support, you must add the bandwidth plugin to your CNI configuration file (default /etc/cni/net.d) and ensure that the binary is included in your CNI bin dir (default /opt/cni/bin).

## **kubernetes.io/egress-bandwidth**

Type: Annotation

Example: kubernetes.io/egress-bandwidth: 10M

Used on: Pod

Egress traffic from a Pod is handled by policing, which simply drops packets in excess of the configured rate. The limits you place on a Pod do not affect the bandwidth of other Pods. To limit the bandwidth on a Pod, write an object definition JSON file and specify the data traffic speed using kubernetes.io/egress-bandwidth annotation. The unit used for specifying egress rate is bits per second, as a [Quantity](#). For example, 10M means 10 megabits per second.

**Note:**

Egress traffic shaping annotation is an experimental feature. If you want to enable traffic shaping support, you must add the bandwidth plugin to your CNI configuration file (default /etc/cni/net.d) and ensure that the binary is included in your CNI bin dir (default /opt/cni/bin).

**beta.kubernetes.io/instance-type (deprecated)**

Type: Label

**Note:**

Starting in v1.17, this label is deprecated in favor of [node.kubernetes.io/instance-type](https://kubernetes.io/docs/concepts/scheduling/kubernetes-scheduler-configuration/#node-labels).

**node.kubernetes.io/instance-type**

Type: Label

Example: node.kubernetes.io/instance-type: "m3.medium"

Used on: Node

The Kubelet populates this with the instance type as defined by the cloud provider. This will be set only if you are using a cloud provider. This setting is handy if you want to target certain workloads to certain instance types, but typically you want to rely on the Kubernetes scheduler to perform resource-based scheduling. You should aim to schedule based on properties rather than on instance types (for example: require a GPU, instead of requiring a g2.2xlarge).

**failure-domain.beta.kubernetes.io/region (deprecated)**

Type: Label

**Note:**

Starting in v1.17, this label is deprecated in favor of [topology.kubernetes.io/region](https://kubernetes.io/docs/concepts/scheduling/kubernetes-scheduler-configuration/#node-labels).

**failure-domain.beta.kubernetes.io/zone (deprecated)**

Type: Label

**Note:**

Starting in v1.17, this label is deprecated in favor of [topology.kubernetes.io/zone](https://kubernetes.io/docs/concepts/scheduling/kubernetes-scheduler-configuration/#node-labels).

**pv.kubernetes.io/bind-completed**

Type: Annotation

Example: pv.kubernetes.io/bind-completed: "yes"

Used on: PersistentVolumeClaim

When this annotation is set on a PersistentVolumeClaim (PVC), that indicates that the lifecycle of the PVC has passed through initial binding setup. When present, that information changes how the control plane interprets the state of PVC objects. The value of this annotation does not matter to Kubernetes.

## **pv.kubernetes.io/bound-by-controller**

Type: Annotation

Example: `pv.kubernetes.io/bound-by-controller: "yes"`

Used on: PersistentVolume, PersistentVolumeClaim

If this annotation is set on a PersistentVolume or PersistentVolumeClaim, it indicates that a storage binding (PersistentVolume → PersistentVolumeClaim, or PersistentVolumeClaim → PersistentVolume) was installed by the [controller](#). If the annotation isn't set, and there is a storage binding in place, the absence of that annotation means that the binding was done manually. The value of this annotation does not matter.

## **pv.kubernetes.io/provisioned-by**

Type: Annotation

Example: `pv.kubernetes.io/provisioned-by: "kubernetes.io/rbd"`

Used on: PersistentVolume

This annotation is added to a PersistentVolume(PV) that has been dynamically provisioned by Kubernetes. Its value is the name of volume plugin that created the volume. It serves both users (to show where a PV comes from) and Kubernetes (to recognize dynamically provisioned PVs in its decisions).

## **pv.kubernetes.io/migrated-to**

Type: Annotation

Example: `pv.kubernetes.io/migrated-to: pd.csi.storage.gke.io`

Used on: PersistentVolume, PersistentVolumeClaim

It is added to a PersistentVolume(PV) and PersistentVolumeClaim(PVC) that is supposed to be dynamically provisioned/deleted by its corresponding CSI driver through the CSIMigration feature gate. When this annotation is set, the Kubernetes components will "stand-down" and the external-provisioner will act on the objects.

## **statefulset.kubernetes.io/pod-name**

Type: Label

Example: `statefulset.kubernetes.io/pod-name: "mystatefulset-7"`

Used on: Pod

When a StatefulSet controller creates a Pod for the StatefulSet, the control plane sets this label on that Pod. The value of the label is the name of the Pod being created.

See [Pod Name Label](#) in the StatefulSet topic for more details.

## **scheduler.alpha.kubernetes.io/node-selector**

Type: Annotation

Example: scheduler.alpha.kubernetes.io/node-selector: "name-of-node-selector"

Used on: Namespace

The [PodNodeSelector](#) uses this annotation key to assign node selectors to pods in namespaces.

## **topology.kubernetes.io/region**

Type: Label

Example: topology.kubernetes.io/region: "us-east-1"

Used on: Node, PersistentVolume

See [topology.kubernetes.io/zone](#).

## **topology.kubernetes.io/zone**

Type: Label

Example: topology.kubernetes.io/zone: "us-east-1c"

Used on: Node, PersistentVolume

**On Node:** The kubelet or the external cloud-controller-manager populates this with the information from the cloud provider. This will be set only if you are using a cloud provider. However, you can consider setting this on nodes if it makes sense in your topology.

**On PersistentVolume:** topology-aware volume provisioners will automatically set node affinity constraints on a PersistentVolume.

A zone represents a logical failure domain. It is common for Kubernetes clusters to span multiple zones for increased availability. While the exact definition of a zone is left to infrastructure implementations, common properties of a zone include very low network latency within a zone, no-cost network traffic within a zone, and failure independence from other zones. For example, nodes within a zone might share a network switch, but nodes in different zones should not.

A region represents a larger domain, made up of one or more zones. It is uncommon for Kubernetes clusters to span multiple regions. While the exact definition of a zone or region is left to infrastructure implementations, common properties of a region include higher network latency between them than within them, non-zero cost for network traffic between them, and failure independence from other zones or regions. For example, nodes within a region might share power infrastructure (e.g. a UPS or generator), but nodes in different regions typically would not.

Kubernetes makes a few assumptions about the structure of zones and regions:

1. regions and zones are hierarchical: zones are strict subsets of regions and no zone can be in 2 regions
2. zone names are unique across regions; for example region "africa-east-1" might be comprised of zones "africa-east-1a" and "africa-east-1b"

It should be safe to assume that topology labels do not change. Even though labels are strictly mutable, consumers of them can assume that a given node is not going to be moved between zones without being destroyed and recreated.

Kubernetes can use this information in various ways. For example, the scheduler automatically tries to spread the Pods in a ReplicaSet across nodes in a single-zone cluster (to reduce the impact of node failures, see [kubernetes.io/hostname](https://kubernetes.io/hostname)). With multiple-zone clusters, this spreading behavior also applies to zones (to reduce the impact of zone failures). This is achieved via *SelectorSpreadPriority*.

*SelectorSpreadPriority* is a best effort placement. If the zones in your cluster are heterogeneous (for example: different numbers of nodes, different types of nodes, or different pod resource requirements), this placement might prevent equal spreading of your Pods across zones. If desired, you can use homogeneous zones (same number and types of nodes) to reduce the probability of unequal spreading.

The scheduler (through the *VolumeZonePredicate* predicate) also will ensure that Pods, that claim a given volume, are only placed into the same zone as that volume. Volumes cannot be attached across zones.

If *PersistentVolumeLabel* does not support automatic labeling of your *PersistentVolumes*, you should consider adding the labels manually (or adding support for *PersistentVolumeLabel*). With *PersistentVolumeLabel*, the scheduler prevents Pods from mounting volumes in a different zone. If your infrastructure doesn't have this constraint, you don't need to add the zone labels to the volumes at all.

## **volume.beta.kubernetes.io/storage-provisioner (deprecated)**

Type: Annotation

Example: `volume.beta.kubernetes.io/storage-provisioner: "k8s.io/minikube-hostpath"`

Used on: *PersistentVolumeClaim*

This annotation has been deprecated since v1.23. See [volume.kubernetes.io/storage-provisioner](https://volume.kubernetes.io/storage-provisioner).

## **volume.beta.kubernetes.io/storage-class (deprecated)**

Type: Annotation

Example: `volume.beta.kubernetes.io/storage-class: "example-class"`

Used on: *PersistentVolume*, *PersistentVolumeClaim*

This annotation can be used for *PersistentVolume*(PV) or *PersistentVolumeClaim*(PVC) to specify the name of [StorageClass](#). When both the `storageClassName` attribute and the

`volume.beta.kubernetes.io/storage-class` annotation are specified, the annotation `volume.beta.kubernetes.io/storage-class` takes precedence over the `storageClassName` attribute.

This annotation has been deprecated. Instead, set the [storageClassName field](#) for the `PersistentVolumeClaim` or `PersistentVolume`.

## **`volume.beta.kubernetes.io/mount-options` (deprecated)**

Type: Annotation

Example : `volume.beta.kubernetes.io/mount-options: "ro,soft"`

Used on: `PersistentVolume`

A Kubernetes administrator can specify additional [mount options](#) for when a `PersistentVolume` is mounted on a node.

## **`volume.kubernetes.io/storage-provisioner`**

Type: Annotation

Used on: `PersistentVolumeClaim`

This annotation is added to a PVC that is supposed to be dynamically provisioned. Its value is the name of a volume plugin that is supposed to provision a volume for this PVC.

## **`volume.kubernetes.io/selected-node`**

Type: Annotation

Used on: `PersistentVolumeClaim`

This annotation is added to a PVC that is triggered by a scheduler to be dynamically provisioned. Its value is the name of the selected node.

## **`volumes.kubernetes.io/controller-managed-attach-detach`**

Type: Annotation

Used on: Node

If a node has the annotation `volumes.kubernetes.io/controller-managed-attach-detach`, its storage attach and detach operations are being managed by the *volume attach/detach* [controller](#).

The value of the annotation isn't important.

## **`node.kubernetes.io/windows-build`**

Type: Label

Example: `node.kubernetes.io/windows-build: "10.0.17763"`

Used on: Node

When the kubelet is running on Microsoft Windows, it automatically labels its Node to record the version of Windows Server in use.

The label's value is in the format "MajorVersion.MinorVersion.BuildNumber".

## **service.kubernetes.io/headless**

Type: Label

Example: `service.kubernetes.io/headless: ""`

Used on: Endpoints

The control plane adds this label to an Endpoints object when the owning Service is headless. To learn more, read [Headless Services](#).

## **service.kubernetes.io/topology-aware-hints (deprecated)**

Example: `service.kubernetes.io/topology-aware-hints: "Auto"`

Used on: Service

This annotation was used for enabling *topology aware hints* on Services. Topology aware hints have since been renamed: the concept is now called [topology aware routing](#). Setting the annotation to Auto, on a Service, configured the Kubernetes control plane to add topology hints on EndpointSlices associated with that Service. You can also explicitly set the annotation to Disabled.

If you are running a version of Kubernetes older than 1.30, check the documentation for that Kubernetes version to see how topology aware routing works in that release.

There are no other valid values for this annotation. If you don't want topology aware hints for a Service, don't add this annotation.

## **service.kubernetes.io/topology-mode**

Type: Annotation

Example: `service.kubernetes.io/topology-mode: Auto`

Used on: Service

This annotation provides a way to define how Services handle network topology; for example, you can configure a Service so that Kubernetes prefers keeping traffic between a client and server within a single topology zone. In some cases this can help reduce costs or improve network performance.

See [Topology Aware Routing](#) for more details.

## **kubernetes.io/service-name**

Type: Label

Example: `kubernetes.io/service-name: "my-website"`

Used on: EndpointSlice

Kubernetes associates [EndpointSlices](#) with [Services](#) using this label.

This label records the [name](#) of the Service that the EndpointSlice is backing. All EndpointSlices should have this label set to the name of their associated Service.

## **kubernetes.io/service-account.name**

Type: Annotation

Example: kubernetes.io/service-account.name: "sa-name"

Used on: Secret

This annotation records the [name](#) of the ServiceAccount that the token (stored in the Secret of type kubernetes.io/service-account-token) represents.

## **kubernetes.io/service-account.uid**

Type: Annotation

Example: kubernetes.io/service-account.uid: da68f9c6-9d26-11e7-b84e-002dc52800da

Used on: Secret

This annotation records the [unique ID](#) of the ServiceAccount that the token (stored in the Secret of type kubernetes.io/service-account-token) represents.

## **kubernetes.io/legacy-token-last-used**

Type: Label

Example: kubernetes.io/legacy-token-last-used: 2022-10-24

Used on: Secret

The control plane only adds this label to Secrets that have the type kubernetes.io/service-account-token. The value of this label records the date (ISO 8601 format, UTC time zone) when the control plane last saw a request where the client authenticated using the service account token.

If a legacy token was last used before the cluster gained the feature (added in Kubernetes v1.26), then the label isn't set.

## **kubernetes.io/legacy-token-invalid-since**

Type: Label

Example: kubernetes.io/legacy-token-invalid-since: 2023-10-27

Used on: Secret

The control plane automatically adds this label to auto-generated Secrets that have the type `kubernetes.io/service-account-token`. This label marks the Secret-based token as invalid for authentication. The value of this label records the date (ISO 8601 format, UTC time zone) when the control plane detects that the auto-generated Secret has not been used for a specified duration (defaults to one year).

### **endpointslice.kubernetes.io/managed-by**

Type: Label

Example: `endpointslice.kubernetes.io/managed-by: endpointslice-controller.k8s.io`

Used on: EndpointSlices

The label is used to indicate the controller or entity that manages the EndpointSlice. This label aims to enable different EndpointSlice objects to be managed by different controllers or entities within the same cluster.

### **endpointslice.kubernetes.io/skip-mirror**

Type: Label

Example: `endpointslice.kubernetes.io/skip-mirror: "true"`

Used on: Endpoints

The label can be set to `"true"` on an Endpoints resource to indicate that the EndpointSliceMirroring controller should not mirror this resource with EndpointSlices.

### **service.kubernetes.io/service-proxy-name**

Type: Label

Example: `service.kubernetes.io/service-proxy-name: "foo-bar"`

Used on: Service

The kube-proxy has this label for custom proxy, which delegates service control to custom proxy.

### **experimental.windows.kubernetes.io/isolation-type (deprecated)**

Type: Annotation

Example: `experimental.windows.kubernetes.io/isolation-type: "hyperv"`

Used on: Pod

The annotation is used to run Windows containers with Hyper-V isolation.

**Note:**

Starting from v1.20, this annotation is deprecated. Experimental Hyper-V support was removed in 1.21.

**ingressclass.kubernetes.io/is-default-class**

Type: Annotation

Example: `ingressclass.kubernetes.io/is-default-class: "true"`

Used on: IngressClass

When a IngressClass resource has this annotation set to "true", new Ingress resource without a class specified will be assigned this default class.

**kubernetes.io/ingress.class (deprecated)**

Type: Annotation

Used on: Ingress

**Note:**

Starting in v1.18, this annotation is deprecated in favor of `spec.ingressClassName`.

**storageclass.kubernetes.io/is-default-class**

Type: Annotation

Example: `storageclass.kubernetes.io/is-default-class: "true"`

Used on: StorageClass

When a single StorageClass resource has this annotation set to "true", new PersistentVolumeClaim resource without a class specified will be assigned this default class.

**alpha.kubernetes.io/provided-node-ip (alpha)**

Type: Annotation

Example: `alpha.kubernetes.io/provided-node-ip: "10.0.0.1"`

Used on: Node

The kubelet can set this annotation on a Node to denote its configured IPv4 and/or IPv6 address.

When kubelet is started with the `--cloud-provider` flag set to any value (includes both external and legacy in-tree cloud providers), it sets this annotation on the Node to denote an IP address set from the command line flag (`--node-ip`). This IP is verified with the cloud provider as valid by the cloud-controller-manager.

## **batch.kubernetes.io/job-completion-index**

Type: Annotation, Label

Example: batch.kubernetes.io/job-completion-index: "3"

Used on: Pod

The Job controller in the kube-controller-manager sets this as a label and annotation for Pods created with Indexed [completion mode](#).

Note the [PodIndexLabel](#) feature gate must be enabled for this to be added as a pod **label**, otherwise it will just be an annotation.

## **batch.kubernetes.io/cronjob-scheduled-timestamp**

Type: Annotation

Example: batch.kubernetes.io/cronjob-scheduled-timestamp: "2016-05-19T03:00:00-07:00"

Used on: Jobs and Pods controlled by CronJobs

This annotation is used to record the original (expected) creation timestamp for a Job, when that Job is part of a CronJob. The control plane sets the value to that timestamp in RFC3339 format. If the Job belongs to a CronJob with a timezone specified, then the timestamp is in that timezone. Otherwise, the timestamp is in controller-manager's local time.

## **kubectrl.kubernetes.io/default-container**

Type: Annotation

Example: kubectrl.kubernetes.io/default-container: "front-end-app"

The value of the annotation is the container name that is default for this Pod. For example, `kubectrl logs` or `kubectrl exec` without `-c` or `--container` flag will use this default container.

## **kubectrl.kubernetes.io/default-logs-container (deprecated)**

Type: Annotation

Example: kubectrl.kubernetes.io/default-logs-container: "front-end-app"

The value of the annotation is the container name that is the default logging container for this Pod. For example, `kubectrl logs` without `-c` or `--container` flag will use this default container.

### **Note:**

This annotation is deprecated. You should use the [kubectrl.kubernetes.io/default-container](#) annotation instead. Kubernetes versions 1.25 and newer ignore this annotation.

## **kubectrl.kubernetes.io/last-applied-configuration**

Type: Annotation

Example: *see following snippet*

```
kubectl.kubernetes.io/last-applied-configuration: >
{"apiVersion":"apps/v1","kind":"Deployment","metadata":{"annotations":
{"name":"example","namespace":"default"},"spec":{"selector":{"matchLabels":{"app.kubernetes.io/
name":"foo"},"template":{"metadata":{"labels":{"app.kubernetes.io/name":"foo"},"spec":
{"containers":[{"image":"container-registry.example/foo-bar:1.42","name":"foo-bar","ports":
[{"containerPort":42}]}}}}}}}
```

Used on: all objects

The kubectl command line tool uses this annotation as a legacy mechanism to track changes. That mechanism has been superseded by [Server-side apply](#).

## **endpoints.kubernetes.io/over-capacity**

Type: Annotation

Example: endpoints.kubernetes.io/over-capacity:truncated

Used on: Endpoints

The [control plane](#) adds this annotation to an [Endpoints](#) object if the associated [Service](#) has more than 1000 backing endpoints. The annotation indicates that the Endpoints object is over capacity and the number of endpoints has been truncated to 1000.

If the number of backend endpoints falls below 1000, the control plane removes this annotation.

## **endpoints.kubernetes.io/last-change-trigger-time**

Type: Annotation

Example: endpoints.kubernetes.io/last-change-trigger-time: "2023-07-20T04:45:21Z"

Used on: Endpoints

This annotation set to an [Endpoints](#) object that represents the timestamp (The timestamp is stored in RFC 3339 date-time string format. For example, '2018-10-22T19:32:52.1Z'). This is timestamp of the last change in some Pod or Service object, that triggered the change to the Endpoints object.

## **control-plane.alpha.kubernetes.io/leader (deprecated)**

Type: Annotation

```
Example: control-plane.alpha.kubernetes.io/
leader={"holderIdentity":"controller-0","leaseDurationSeconds":
15,"acquireTime":"2023-01-19T13:12:57Z","renewTime":"2023-01-19T13:13:54Z","leaderTransitions
":1}
```

Used on: Endpoints

The [control plane](#) previously set annotation on an [Endpoints](#) object. This annotation provided the following detail:

- Who is the current leader.
- The time when the current leadership was acquired.
- The duration of the lease (of the leadership) in seconds.
- The time the current lease (the current leadership) should be renewed.
- The number of leadership transitions that happened in the past.

Kubernetes now uses [Leases](#) to manage leader assignment for the Kubernetes control plane.

## **batch.kubernetes.io/job-tracking (deprecated)**

Type: Annotation

Example: batch.kubernetes.io/job-tracking: ""

Used on: Jobs

The presence of this annotation on a Job used to indicate that the control plane is [tracking the Job status using finalizers](#). Adding or removing this annotation no longer has an effect (Kubernetes v1.27 and later) All Jobs are tracked with finalizers.

## **job-name (deprecated)**

Type: Label

Example: job-name: "pi"

Used on: Jobs and Pods controlled by Jobs

### **Note:**

Starting from Kubernetes 1.27, this label is deprecated. Kubernetes 1.27 and newer ignore this label and use the prefixed job-name label.

## **controller-uid (deprecated)**

Type: Label

Example: controller-uid: "\$UID"

Used on: Jobs and Pods controlled by Jobs

### **Note:**

Starting from Kubernetes 1.27, this label is deprecated. Kubernetes 1.27 and newer ignore this label and use the prefixed controller-uid label.

## **batch.kubernetes.io/job-name**

Type: Label

Example: `batch.kubernetes.io/job-name: "pi"`

Used on: Jobs and Pods controlled by Jobs

This label is used as a user-friendly way to get Pods corresponding to a Job. The job-name comes from the name of the Job and allows for an easy way to get Pods corresponding to the Job.

## **batch.kubernetes.io/controller-uid**

Type: Label

Example: `batch.kubernetes.io/controller-uid: "$UID"`

Used on: Jobs and Pods controlled by Jobs

This label is used as a programmatic way to get all Pods corresponding to a Job. The controller-uid is a unique identifier that gets set in the selector field so the Job controller can get all the corresponding Pods.

## **scheduler.alpha.kubernetes.io/defaultTolerations**

Type: Annotation

Example: `scheduler.alpha.kubernetes.io/defaultTolerations: '[{"operator": "Equal", "value": "value1", "effect": "NoSchedule", "key": "dedicated-node"}]'`

Used on: Namespace

This annotation requires the [PodTolerationRestriction](#) admission controller to be enabled. This annotation key allows assigning tolerations to a namespace and any new pods created in this namespace would get these tolerations added.

## **scheduler.alpha.kubernetes.io/tolerationsWhitelist**

Type: Annotation

Example: `scheduler.alpha.kubernetes.io/tolerationsWhitelist: '[{"operator": "Exists", "effect": "NoSchedule", "key": "dedicated-node"}]'`

Used on: Namespace

This annotation is only useful when the (Alpha) [PodTolerationRestriction](#) admission controller is enabled. The annotation value is a JSON document that defines a list of allowed tolerations for the namespace it annotates. When you create a Pod or modify its tolerations, the API server checks the tolerations to see if they are mentioned in the allow list. The pod is admitted only if the check succeeds.

## **scheduler.alpha.kubernetes.io/preferAvoidPods (deprecated)**

Type: Annotation

Used on: Node

This annotation requires the [NodePreferAvoidPods scheduling plugin](#) to be enabled. The plugin is deprecated since Kubernetes 1.22. Use [Taints and Tolerations](#) instead.

## **node.kubernetes.io/not-ready**

Type: Taint

Example: `node.kubernetes.io/not-ready: "NoExecute"`

Used on: Node

The Node controller detects whether a Node is ready by monitoring its health and adds or removes this taint accordingly.

## **node.kubernetes.io/unreachable**

Type: Taint

Example: `node.kubernetes.io/unreachable: "NoExecute"`

Used on: Node

The Node controller adds the taint to a Node corresponding to the [NodeCondition](#) Ready being Unknown.

## **node.kubernetes.io/unschedulable**

Type: Taint

Example: `node.kubernetes.io/unschedulable: "NoSchedule"`

Used on: Node

The taint will be added to a node when initializing the node to avoid race condition.

## **node.kubernetes.io/memory-pressure**

Type: Taint

Example: `node.kubernetes.io/memory-pressure: "NoSchedule"`

Used on: Node

The kubelet detects memory pressure based on `memory.available` and `allocatableMemory.available` observed on a Node. The observed values are then compared to the corresponding thresholds that can be set on the kubelet to determine if the Node condition and taint should be added/removed.

## **node.kubernetes.io/disk-pressure**

Type: Taint

Example: `node.kubernetes.io/disk-pressure : "NoSchedule"`

Used on: Node

The kubelet detects disk pressure based on `imagefs.available`, `imagefs.inodesFree`, `nodefs.available` and `nodefs.inodesFree` (Linux only) observed on a Node. The observed values are then compared to the corresponding thresholds that can be set on the kubelet to determine if the Node condition and taint should be added/removed.

## **node.kubernetes.io/network-unavailable**

Type: Taint

Example: `node.kubernetes.io/network-unavailable: "NoSchedule"`

Used on: Node

This is initially set by the kubelet when the cloud provider used indicates a requirement for additional network configuration. Only when the route on the cloud is configured properly will the taint be removed by the cloud provider.

## **node.kubernetes.io/pid-pressure**

Type: Taint

Example: `node.kubernetes.io/pid-pressure: "NoSchedule"`

Used on: Node

The kubelet checks D-value of the size of `/proc/sys/kernel/pid_max` and the PIDs consumed by Kubernetes on a node to get the number of available PIDs that referred to as the `pid.available` metric. The metric is then compared to the corresponding threshold that can be set on the kubelet to determine if the node condition and taint should be added/removed.

## **node.kubernetes.io/out-of-service**

Type: Taint

Example: `node.kubernetes.io/out-of-service:NoExecute`

Used on: Node

A user can manually add the taint to a Node marking it out-of-service. If the `NodeOutOfServiceVolumeDetach` [feature gate](#) is enabled on kube-controller-manager, and a Node is marked out-of-service with this taint, the Pods on the node will be forcefully deleted if there are no matching tolerations on it and volume detach operations for the Pods terminating on the node will happen immediately. This allows the Pods on the out-of-service node to recover quickly on a different node.

### **Caution:**

Refer to [Non-graceful node shutdown](#) for further details about when and how to use this taint.

## **node.cloudprovider.kubernetes.io/uninitialized**

Type: Taint

Example: node.cloudprovider.kubernetes.io/uninitialized: "NoSchedule"

Used on: Node

Sets this taint on a Node to mark it as unusable, when kubelet is started with the "external" cloud provider, until a controller from the cloud-controller-manager initializes this Node, and then removes the taint.

## **node.cloudprovider.kubernetes.io/shutdown**

Type: Taint

Example: node.cloudprovider.kubernetes.io/shutdown: "NoSchedule"

Used on: Node

If a Node is in a cloud provider specified shutdown state, the Node gets tainted accordingly with node.cloudprovider.kubernetes.io/shutdown and the taint effect of NoSchedule.

## **feature.node.kubernetes.io/\***

Type: Label

Example: feature.node.kubernetes.io/network-sriov.capable: "true"

Used on: Node

These labels are used by the Node Feature Discovery (NFD) component to advertise features on a node. All built-in labels use the feature.node.kubernetes.io label namespace and have the format feature.node.kubernetes.io/<feature-name>: "true". NFD has many extension points for creating vendor and application-specific labels. For details, see the [customization guide](#).

## **nfd.node.kubernetes.io/master.version**

Type: Annotation

Example: nfd.node.kubernetes.io/master.version: "v0.6.0"

Used on: Node

For node(s) where the Node Feature Discovery (NFD) [master](#) is scheduled, this annotation records the version of the NFD master. It is used for informative use only.

## **nfd.node.kubernetes.io/worker.version**

Type: Annotation

Example: nfd.node.kubernetes.io/worker.version: "v0.4.0"

Used on: Nodes

This annotation records the version for a Node Feature Discovery's [worker](#) if there is one running on a node. It's used for informative use only.

### **nfd.node.kubernetes.io/feature-labels**

Type: Annotation

Example: `nfd.node.kubernetes.io/feature-labels: "cpu-cpuid.ADX,cpu-cpuid.AESNI,cpu-hardware_multithreading,kernel-version.full"`

Used on: Nodes

This annotation records a comma-separated list of node feature labels managed by [Node Feature Discovery](#) (NFD). NFD uses this for an internal mechanism. You should not edit this annotation yourself.

### **nfd.node.kubernetes.io/extended-resources**

Type: Annotation

Example: `nfd.node.kubernetes.io/extended-resources: "accelerator.acme.example/q500,example.com/coprocessor-fx5"`

Used on: Nodes

This annotation records a comma-separated list of [extended resources](#) managed by [Node Feature Discovery](#) (NFD). NFD uses this for an internal mechanism. You should not edit this annotation yourself.

### **nfd.node.kubernetes.io/node-name**

Type: Label

Example: `nfd.node.kubernetes.io/node-name: node-1`

Used on: Nodes

It specifies which node the NodeFeature object is targeting. Creators of NodeFeature objects must set this label and consumers of the objects are supposed to use the label for filtering features designated for a certain node.

#### **Note:**

These Node Feature Discovery (NFD) labels or annotations only apply to the nodes where NFD is running. To learn more about NFD and its components go to its official [documentation](#).

### **service.beta.kubernetes.io/aws-load-balancer-access-log-emit-interval (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-access-log-emit-interval: "5"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer for a Service based on this annotation. The value determines how often the load balancer writes log entries. For example, if you set the value to 5, the log writes occur 5 seconds apart.

### **service.beta.kubernetes.io/aws-load-balancer-access-log-enabled (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-access-log-enabled: "false"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer for a Service based on this annotation. Access logging is enabled if you set the annotation to "true".

### **service.beta.kubernetes.io/aws-load-balancer-access-log-s3-bucket-name (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-access-log-enabled: example`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer for a Service based on this annotation. The load balancer writes logs to an S3 bucket with the name you specify.

### **service.beta.kubernetes.io/aws-load-balancer-access-log-s3-bucket-prefix (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-access-log-enabled: "/example"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer for a Service based on this annotation. The load balancer writes log objects with the prefix that you specify.

### **service.beta.kubernetes.io/aws-load-balancer-additional-resource-tags (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-additional-resource-tags: "Environment=demo,Project=example"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures tags (an AWS concept) for a load balancer based on the comma-separated key/value pairs in the value of this annotation.

## **service.beta.kubernetes.io/aws-load-balancer-alpn-policy (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-alpn-policy: HTTP2Optional`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

## **service.beta.kubernetes.io/aws-load-balancer-attributes (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-attributes: "deletion_protection.enabled=true"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

## **service.beta.kubernetes.io/aws-load-balancer-backend-protocol (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-backend-protocol: tcp`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer listener based on the value of this annotation.

## **service.beta.kubernetes.io/aws-load-balancer-connection-draining-enabled (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-connection-draining-enabled: "false"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures the load balancer based on this annotation. The load balancer's connection draining setting depends on the value you set.

## **service.beta.kubernetes.io/aws-load-balancer-connection-draining-timeout (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-connection-draining-timeout: "60"`

Used on: Service

If you configure [connection draining](#) for a Service of type: `LoadBalancer`, and you use the AWS cloud, the integration configures the draining period based on this annotation. The value you set determines the draining timeout in seconds.

## **service.beta.kubernetes.io/aws-load-balancer-ip-address-type (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-ip-address-type: ipv4`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

## **service.beta.kubernetes.io/aws-load-balancer-connection-idle-timeout (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-connection-idle-timeout: "60"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The load balancer has a configured idle timeout period (in seconds) that applies to its connections. If no data has been sent or received by the time that the idle timeout period elapses, the load balancer closes the connection.

## **service.beta.kubernetes.io/aws-load-balancer-cross-zone-load-balancing-enabled (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-cross-zone-load-balancing-enabled: "true"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. If you set this annotation to "true", each load balancer node distributes requests evenly across the registered targets in all enabled [availability zones](#). If you disable cross-zone load balancing, each load balancer node distributes requests evenly across the registered targets in its availability zone only.

## **service.beta.kubernetes.io/aws-load-balancer-eip-allocations (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-eip-allocations: "eipalloc-01bcdef23bcdef456,eipalloc-def1234abc4567890"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The value is a comma-separated list of elastic IP address allocation IDs.

This annotation is only relevant for Services of type: LoadBalancer, where the load balancer is an AWS Network Load Balancer.

## **service.beta.kubernetes.io/aws-load-balancer-extra-security-groups (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-extra-security-groups: "sg-12abcd3456,sg-34dcba6543"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value is a comma-separated list of extra AWS VPC security groups to configure for the load balancer.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-healthy-threshold (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-healthy-threshold: "3"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value specifies the number of successive successful health checks required for a backend to be considered healthy for traffic.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-interval (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-interval: "30"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value specifies the interval, in seconds, between health check probes made by the load balancer.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-path (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-path: /healthcheck`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value determines the path part of the URL that is used for HTTP health checks.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-port (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-port: "24"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value determines which port the load balancer connects to when performing health checks.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-protocol (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-protocol: TCP`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value determines how the load balancer checks the health of backend targets.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-timeout (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-timeout: "3"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value specifies the number of seconds before a probe that hasn't yet succeeded is automatically treated as having failed.

## **service.beta.kubernetes.io/aws-load-balancer-healthcheck-unhealthy-threshold (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-healthcheck-unhealthy-threshold: "3"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. The annotation value specifies the number of successive unsuccessful health checks required for a backend to be considered unhealthy for traffic.

## **service.beta.kubernetes.io/aws-load-balancer-internal (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-internal: "true"`

Used on: Service

The cloud controller manager integration with AWS elastic load balancing configures a load balancer based on this annotation. When you set this annotation to "true", the integration configures an internal load balancer.

If you use the [AWS load balancer controller](#), see [service.beta.kubernetes.io/aws-load-balancer-scheme](#).

## **service.beta.kubernetes.io/aws-load-balancer-manage-backend-security-group-rules (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-manage-backend-security-group-rules: "true"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-name (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-name: my-elb`

Used on: Service

If you set this annotation on a Service, and you also annotate that Service with `service.beta.kubernetes.io/aws-load-balancer-type: "external"`, and you use the [AWS load balancer controller](#) in your cluster, then the AWS load balancer controller sets the name of that load balancer to the value you set for *this* annotation.

See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-nlb-target-type (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-nlb-target-type: "true"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-private-ipv4-addresses (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-private-ipv4-addresses: "198.51.100.0,198.51.100.64"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-proxy-protocol (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-proxy-protocol: ""`

Used on: Service

The official Kubernetes integration with AWS elastic load balancing configures a load balancer based on this annotation. The only permitted value is `""`, which indicates that the load balancer should wrap TCP connections to the backend Pod with the PROXY protocol.

### **service.beta.kubernetes.io/aws-load-balancer-scheme (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-scheme: internal`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-security-groups (deprecated)**

Example: `service.beta.kubernetes.io/aws-load-balancer-security-groups: "sg-53fae93f,sg-8725gr62r"`

Used on: Service

The AWS load balancer controller uses this annotation to specify a comma separated list of security groups you want to attach to an AWS load balancer. Both name and ID of security are supported where name matches a Name tag, not the groupName attribute.

When this annotation is added to a Service, the load-balancer controller attaches the security groups referenced by the annotation to the load balancer. If you omit this annotation, the AWS load balancer controller automatically creates a new security group and attaches it to the load balancer.

#### **Note:**

Kubernetes v1.27 and later do not directly set or read this annotation. However, the AWS load balancer controller (part of the Kubernetes project) does still use the `service.beta.kubernetes.io/aws-load-balancer-security-groups` annotation.

### **service.beta.kubernetes.io/load-balancer-source-ranges (deprecated)**

Example: `service.beta.kubernetes.io/load-balancer-source-ranges: "192.0.2.0/25"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. You should set `.spec.loadBalancerSourceRanges` for the Service instead.

### **service.beta.kubernetes.io/aws-load-balancer-ssl-cert (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-ssl-cert: "arn:aws:acm:us-east-1:123456789012:certificate/12345678-1234-1234-1234-123456789012"`

Used on: Service

The official integration with AWS elastic load balancing configures TLS for a Service of type: `LoadBalancer` based on this annotation. The value of the annotation is the AWS Resource Name (ARN) of the X.509 certificate that the load balancer listener should use.

(The TLS protocol is based on an older technology that abbreviates to SSL.)

### **service.beta.kubernetes.io/aws-load-balancer-ssl-negotiation-policy (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-ssl-negotiation-policy: ELBSecurityPolicy-TLS-1-2-2017-01`

The official integration with AWS elastic load balancing configures TLS for a Service of type: LoadBalancer based on this annotation. The value of the annotation is the name of an AWS policy for negotiating TLS with a client peer.

### **service.beta.kubernetes.io/aws-load-balancer-ssl-ports (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-ssl-ports: "**"`

The official integration with AWS elastic load balancing configures TLS for a Service of type: LoadBalancer based on this annotation. The value of the annotation is either "\*\*", which means that all the load balancer's ports should use TLS, or it is a comma separated list of port numbers.

### **service.beta.kubernetes.io/aws-load-balancer-subnets (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-subnets: "private-a,private-b"`

Kubernetes' official integration with AWS uses this annotation to configure a load balancer and determine in which AWS availability zones to deploy the managed load balancing service. The value is either a comma separated list of subnet names, or a comma separated list of subnet IDs.

### **service.beta.kubernetes.io/aws-load-balancer-target-group-attributes (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-target-group-attributes: "stickiness.enabled=true,stickiness.type=source_ip"`

Used on: Service

The [AWS load balancer controller](#) uses this annotation. See [annotations](#) in the AWS load balancer controller documentation.

### **service.beta.kubernetes.io/aws-load-balancer-target-node-labels (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-target-node-labels: "kubernetes.io/os=Linux,topology.kubernetes.io/region=us-east-2"`

Kubernetes' official integration with AWS uses this annotation to determine which nodes in your cluster should be considered as valid targets for the load balancer.

### **service.beta.kubernetes.io/aws-load-balancer-type (beta)**

Example: `service.beta.kubernetes.io/aws-load-balancer-type: external`

Kubernetes' official integrations with AWS use this annotation to determine whether the AWS cloud provider integration should manage a Service of type: LoadBalancer.

There are two permitted values:

`nlb`

the cloud controller manager configures a Network Load Balancer

`external`

the cloud controller manager does not configure any load balancer

If you deploy a Service of type: `LoadBalancer` on AWS, and you don't set any `service.beta.kubernetes.io/aws-load-balancer-type` annotation, the AWS integration deploys a classic Elastic Load Balancer. This behavior, with no annotation present, is the default unless you specify otherwise.

When you set this annotation to `external` on a Service of type: `LoadBalancer`, and your cluster has a working deployment of the AWS Load Balancer controller, then the AWS Load Balancer controller attempts to deploy a load balancer based on the Service specification.

#### Caution:

Do not modify or add the `service.beta.kubernetes.io/aws-load-balancer-type` annotation on an existing Service object. See the AWS documentation on this topic for more details.

### **`service.beta.kubernetes.io/azure-load-balancer-disable-tcp-reset` (deprecated)**

Example: `service.beta.kubernetes.io/azure-load-balancer-disable-tcp-reset: "false"`

Used on: Service

This annotation only works for Azure standard load balancer backed service. This annotation is used on the Service to specify whether the load balancer should disable or enable TCP reset on idle timeout. If enabled, it helps applications to behave more predictably, to detect the termination of a connection, remove expired connections and initiate new connections. You can set the value to be either true or false.

See [Load Balancer TCP Reset](#) for more information.

#### Note:

This annotation is deprecated.

### **`pod-security.kubernetes.io/enforce`**

Type: Label

Example: `pod-security.kubernetes.io/enforce: "baseline"`

Used on: Namespace

Value **must** be one of `privileged`, `baseline`, or `restricted` which correspond to [Pod Security Standard](#) levels. Specifically, the `enforce` label *prohibits* the creation of any Pod in the labeled Namespace which does not meet the requirements outlined in the indicated level.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

### **`pod-security.kubernetes.io/enforce-version`**

Type: Label

Example: `pod-security.kubernetes.io/enforce-version: "1.30"`

Used on: Namespace

Value **must** be latest or a valid Kubernetes version in the format v<major>.<minor>. This determines the version of the [Pod Security Standard](#) policies to apply when validating a Pod.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

## **pod-security.kubernetes.io/audit**

Type: Label

Example: pod-security.kubernetes.io/audit: "baseline"

Used on: Namespace

Value **must** be one of privileged, baseline, or restricted which correspond to [Pod Security Standard](#) levels. Specifically, the audit label does not prevent the creation of a Pod in the labeled Namespace which does not meet the requirements outlined in the indicated level, but adds an this annotation to the Pod.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

## **pod-security.kubernetes.io/audit-version**

Type: Label

Example: pod-security.kubernetes.io/audit-version: "1.30"

Used on: Namespace

Value **must** be latest or a valid Kubernetes version in the format v<major>.<minor>. This determines the version of the [Pod Security Standard](#) policies to apply when validating a Pod.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

## **pod-security.kubernetes.io/warn**

Type: Label

Example: pod-security.kubernetes.io/warn: "baseline"

Used on: Namespace

Value **must** be one of privileged, baseline, or restricted which correspond to [Pod Security Standard](#) levels. Specifically, the warn label does not prevent the creation of a Pod in the labeled Namespace which does not meet the requirements outlined in the indicated level, but returns a warning to the user after doing so. Note that warnings are also displayed when creating or updating objects that contain Pod templates, such as Deployments, Jobs, StatefulSets, etc.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

## **pod-security.kubernetes.io/warn-version**

Type: Label

Example: `pod-security.kubernetes.io/warn-version: "1.30"`

Used on: Namespace

Value **must** be latest or a valid Kubernetes version in the format `v<major>.<minor>`. This determines the version of the [Pod Security Standard](#) policies to apply when validating a submitted Pod. Note that warnings are also displayed when creating or updating objects that contain Pod templates, such as Deployments, Jobs, StatefulSets, etc.

See [Enforcing Pod Security at the Namespace Level](#) for more information.

## **`rbac.authorization.kubernetes.io/autoupdate`**

Type: Annotation

Example: `rbac.authorization.kubernetes.io/autoupdate: "false"`

Used on: ClusterRole, ClusterRoleBinding, Role, RoleBinding

When this annotation is set to `"true"` on default RBAC objects created by the API server, they are automatically updated at server start to add missing permissions and subjects (extra permissions and subjects are left in place). To prevent autoupdating a particular role or rolebinding, set this annotation to `"false"`. If you create your own RBAC objects and set this annotation to `"false"`, `kubectl auth reconcile` (which allows reconciling arbitrary RBAC objects in a [manifest](#)) respects this annotation and does not automatically add missing permissions and subjects.

## **`kubernetes.io/psp (deprecated)`**

Type: Annotation

Example: `kubernetes.io/psp: restricted`

Used on: Pod

This annotation was only relevant if you were using [PodSecurityPolicy](#) objects. Kubernetes v1.30 does not support the PodSecurityPolicy API.

When the PodSecurityPolicy admission controller admitted a Pod, the admission controller modified the Pod to have this annotation. The value of the annotation was the name of the PodSecurityPolicy that was used for validation.

## **`seccomp.security.alpha.kubernetes.io/pod (non-functional)`**

Type: Annotation

Used on: Pod

Kubernetes before v1.25 allowed you to configure seccomp behavior using this annotation. See [Restrict a Container's Syscalls with seccomp](#) to learn the supported way to specify seccomp restrictions for a Pod.

## **container.seccomp.security.alpha.kubernetes.io/[NAME] (non-functional)**

Type: Annotation

Used on: Pod

Kubernetes before v1.25 allowed you to configure seccomp behavior using this annotation. See [Restrict a Container's Syscalls with seccomp](#) to learn the supported way to specify seccomp restrictions for a Pod.

## **snapshot.storage.kubernetes.io/allow-volume-mode-change**

Type: Annotation

Example: `snapshot.storage.kubernetes.io/allow-volume-mode-change: "true"`

Used on: VolumeSnapshotContent

Value can either be true or false. This determines whether a user can modify the mode of the source volume when a PersistentVolumeClaim is being created from a VolumeSnapshot.

Refer to [Converting the volume mode of a Snapshot](#) and the [Kubernetes CSI Developer Documentation](#) for more information.

## **scheduler.alpha.kubernetes.io/critical-pod (deprecated)**

Type: Annotation

Example: `scheduler.alpha.kubernetes.io/critical-pod: ""`

Used on: Pod

This annotation lets Kubernetes control plane know about a Pod being a critical Pod so that the descheduler will not remove this Pod.

### **Note:**

Starting in v1.16, this annotation was removed in favor of [Pod Priority](#).

## **Annotations used for audit**

- [authorization.k8s.io/decision](#)
- [authorization.k8s.io/reason](#)
- [insecure-sha1.invalid-cert.kubernetes.io/\\$hostname](#)
- [missing-san.invalid-cert.kubernetes.io/\\$hostname](#)
- [pod-security.kubernetes.io/audit-violations](#)
- [pod-security.kubernetes.io/enforce-policy](#)
- [pod-security.kubernetes.io/exempt](#)
- [validation.policy.admission.k8s.io/validation\\_failure](#)

See more details on [Audit Annotations](#).

# kubeadm

## **kubeadm.alpha.kubernetes.io/cri-socket**

Type: Annotation

Example: kubeadm.alpha.kubernetes.io/cri-socket: unix:///run/containerd/container.sock

Used on: Node

Annotation that kubeadm uses to preserve the CRI socket information given to kubeadm at init/join time for later use. kubeadm annotates the Node object with this information. The annotation remains "alpha", since ideally this should be a field in KubeletConfiguration instead.

## **kubeadm.kubernetes.io/etcd.advertise-client-urls**

Type: Annotation

Example: kubeadm.kubernetes.io/etcd.advertise-client-urls: https://172.17.0.18:2379

Used on: Pod

Annotation that kubeadm places on locally managed etcd Pods to keep track of a list of URLs where etcd clients should connect to. This is used mainly for etcd cluster health check purposes.

## **kubeadm.kubernetes.io/kube-apiserver.advertise-address.endpoint**

Type: Annotation

Example: kubeadm.kubernetes.io/kube-apiserver.advertise-address.endpoint: https://172.17.0.18:6443

Used on: Pod

Annotation that kubeadm places on locally managed kube-apiserver Pods to keep track of the exposed advertise address/port endpoint for that API server instance.

## **kubeadm.kubernetes.io/component-config.hash**

Type: Annotation

Example: kubeadm.kubernetes.io/component-config.hash:  
2c26b46b68ffc68ff99b453c1d30413413422d706483bfa0f98a5e886266e7ae

Used on: ConfigMap

Annotation that kubeadm places on ConfigMaps that it manages for configuring components. It contains a hash (SHA-256) used to determine if the user has applied settings different from the kubeadm defaults for a particular component.

## **node-role.kubernetes.io/control-plane**

Type: Label

Used on: Node

A marker label to indicate that the node is used to run control plane components. The kubeadm tool applies this label to the control plane nodes that it manages. Other cluster management tools typically also set this taint.

You can label control plane nodes with this label to make it easier to schedule Pods only onto these nodes, or to avoid running Pods on the control plane. If this label is set, the [EndpointSlice controller](#) ignores that node while calculating Topology Aware Hints.

## **node-role.kubernetes.io/control-plane**

Type: Taint

Example: node-role.kubernetes.io/control-plane:NoSchedule

Used on: Node

Taint that kubeadm applies on control plane nodes to restrict placing Pods and allow only specific pods to schedule on them.

If this Taint is applied, control plane nodes allow only critical workloads to be scheduled onto them. You can manually remove this taint with the following command on a specific node.

```
kubecttl taint nodes <node-name> node-role.kubernetes.io/control-plane:NoSchedule-
```

## **node-role.kubernetes.io/master (deprecated)**

Type: Taint

Used on: Node

Example: node-role.kubernetes.io/master:NoSchedule

Taint that kubeadm previously applied on control plane nodes to allow only critical workloads to schedule on them. Replaced by the [node-role.kubernetes.io/control-plane](#) taint. kubeadm no longer sets or uses this deprecated taint.

# **Audit Annotations**

This page serves as a reference for the audit annotations of the kubernetes.io namespace. These annotations apply to Event object from API group audit.k8s.io.

### **Note:**

The following annotations are not used within the Kubernetes API. When you [enable auditing](#) in your cluster, audit event data is written using Event from API group audit.k8s.io. The annotations apply to audit events. Audit events are different from objects in the [Event API](#) (API group events.k8s.io).

## pod-security.kubernetes.io/exempt

Example: pod-security.kubernetes.io/exempt: namespace

Value **must** be one of user, namespace, or runtimeClass which correspond to [Pod Security Exemption](#) dimensions. This annotation indicates on which dimension was based the exemption from the PodSecurity enforcement.

## pod-security.kubernetes.io/enforce-policy

Example: pod-security.kubernetes.io/enforce-policy: restricted:latest

Value **must** be privileged:<version>, baseline:<version>, restricted:<version> which correspond to [Pod Security Standard](#) levels accompanied by a version which **must** be latest or a valid Kubernetes version in the format v<MAJOR>.<MINOR>. This annotations informs about the enforcement level that allowed or denied the pod during PodSecurity admission.

See [Pod Security Standards](#) for more information.

## pod-security.kubernetes.io/audit-violations

Example: pod-security.kubernetes.io/audit-violations: would violate PodSecurity "restricted:latest": allowPrivilegeEscalation != false (container "example" must set securityContext.allowPrivilegeEscalation=false), ...

Value details an audit policy violation, it contains the [Pod Security Standard](#) level that was transgressed as well as the specific policies on the fields that were violated from the PodSecurity enforcement.

See [Pod Security Standards](#) for more information.

## authorization.k8s.io/decision

Example: authorization.k8s.io/decision: "forbid"

This annotation indicates whether or not a request was authorized in Kubernetes audit logs.

See [Auditing](#) for more information.

## authorization.k8s.io/reason

Example: authorization.k8s.io/reason: "Human-readable reason for the decision"

This annotation gives reason for the [decision](#) in Kubernetes audit logs.

See [Auditing](#) for more information.

## **missing-san.invalid-cert.kubernetes.io/\$hostname**

Example:

```
missing-san.invalid-cert.kubernetes.io/example-svc.example-namespace.svc: "relies on a legacy Common Name field instead of the SAN extension for subject validation"
```

Used by Kubernetes version v1.24 and later

This annotation indicates a webhook or aggregated API server is using an invalid certificate that is missing subjectAltNames. Support for these certificates was disabled by default in Kubernetes 1.19, and removed in Kubernetes 1.23.

Requests to endpoints using these certificates will fail. Services using these certificates should replace them as soon as possible to avoid disruption when running in Kubernetes 1.23+ environments.

There's more information about this in the Go documentation: [X.509 CommonName deprecation](#).

## **insecure-sha1.invalid-cert.kubernetes.io/\$hostname**

Example: `insecure-sha1.invalid-cert.kubernetes.io/example-svc.example-namespace.svc: "uses an insecure SHA-1 signature"`

Used by Kubernetes version v1.24 and later

This annotation indicates a webhook or aggregated API server is using an insecure certificate signed with a SHA-1 hash. Support for these insecure certificates is disabled by default in Kubernetes 1.24, and will be removed in a future release.

Services using these certificates should replace them as soon as possible, to ensure connections are secured properly and to avoid disruption in future releases.

There's more information about this in the Go documentation: [Rejecting SHA-1 certificates](#).

## **validation.policy.admission.k8s.io/validation\_failure**

Example: `validation.policy.admission.k8s.io/validation_failure: [{"message": "Invalid value", "policy": "policy.example.com", "binding": "policybinding.example.com", "expressionIndex": "1", "validationActions": ["Audit"]}]"`

Used by Kubernetes version v1.27 and later.

This annotation indicates that a admission policy validation evaluated to false for an API request, or that the validation resulted in an error while the policy was configured with failurePolicy: Fail.

The value of the annotation is a JSON object. The message in the JSON provides the message about the validation failure.

The `policy`, `binding` and `expressionIndex` in the JSON identifies the name of the `ValidatingAdmissionPolicy`, the name of the `ValidatingAdmissionPolicyBinding` and the index in the policy validations of the CEL expressions that failed, respectively.

The `validationActions` shows what actions were taken for this validation failure. See [Validating Admission Policy](#) for more details about `validationActions`.

# Kubernetes API

Kubernetes' API is the application that serves Kubernetes functionality through a RESTful interface and stores the state of the cluster.

Kubernetes resources and "records of intent" are all stored as API objects, and modified via RESTful calls to the API. The API allows configuration to be managed in a declarative way. Users can interact with the Kubernetes API directly, or via tools like `kubectl`. The core Kubernetes API is flexible and can also be extended to support custom resources.

[Common Parameters](#)

## Workload Resources

---

[Pod](#)

Pod is a collection of containers that can run on a host.

### [PodTemplate](#)

PodTemplate describes a template for creating copies of a predefined pod.

### [ReplicationController](#)

ReplicationController represents the configuration of a replication controller.

### [ReplicaSet](#)

ReplicaSet ensures that a specified number of pod replicas are running at any given time.

### [Deployment](#)

Deployment enables declarative updates for Pods and ReplicaSets.

### [StatefulSet](#)

StatefulSet represents a set of pods with consistent identities.

### [ControllerRevision](#)

ControllerRevision implements an immutable snapshot of state data.

### [DaemonSet](#)

DemonSet represents the configuration of a daemon set.

### [Job](#)

Job represents the configuration of a single job.

### [CronJob](#)

CronJob represents the configuration of a single cron job.

### [HorizontalPodAutoscaler](#)

configuration of a horizontal pod autoscaler.

### [HorizontalPodAutoscaler](#)

HorizontalPodAutoscaler is the configuration for a horizontal pod autoscaler, which automatically manages the replica count of any resource implementing the scale subresource based on the metrics specified.

### [PriorityClass](#)

PriorityClass defines mapping from a priority class name to the priority integer value.

### [PodSchedulingContext v1alpha2](#)

PodSchedulingContext objects hold information that is needed to schedule a Pod with ResourceClaims that use "WaitForFirstConsumer" allocation mode.

### [ResourceClaim v1alpha2](#)

ResourceClaim describes which resources are needed by a resource consumer.

### [ResourceClaimTemplate v1alpha2](#)

ResourceClaimTemplate is used to produce ResourceClaim objects.

### [ResourceClass v1alpha2](#)

ResourceClass is used by administrators to influence how resources are allocated.

## Pod

Pod is a collection of containers that can run on a host.

apiVersion: v1

```
import "k8s.io/api/core/v1"
```

## Pod

Pod is a collection of containers that can run on a host. This resource is created by clients and scheduled onto hosts.

- 
- **apiVersion:** v1
  - **kind:** Pod
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PodSpec](#))

Specification of the desired behavior of the pod. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([PodStatus](#))

Most recently observed status of the pod. This data may not be up to date. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

# PodSpec

PodSpec is a description of a pod.

---

## Containers

- **containers** ([][Container](#)), required

*Patch strategy: merge on key name*

List of containers belonging to the pod. Containers cannot currently be added or removed. There must be at least one container in a Pod. Cannot be updated.

- **initContainers** ([][Container](#))

*Patch strategy: merge on key name*

List of initialization containers belonging to the pod. Init containers are executed in order prior to containers being started. If any init container fails, the pod is considered to have failed and is handled according to its restartPolicy. The name for an init container or normal container must be unique among all containers. Init containers may not have Lifecycle actions, Readiness probes, Liveness probes, or Startup probes. The resourceRequirements of an init container are taken into account during scheduling by finding the highest request/limit for each resource type, and then using the max of that value or the sum of the normal containers. Limits are applied to init containers in a similar fashion. Init containers cannot currently be added or removed. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/workloads/pods/init-containers/>

- **ephemeralContainers** ([][EphemeralContainer](#))

*Patch strategy: merge on key name*

List of ephemeral containers run in this pod. Ephemeral containers may be run in an existing pod to perform user-initiated actions such as debugging. This list cannot be specified when creating a pod, and it cannot be modified by updating the pod spec. In order to add an ephemeral container to an existing pod, use the pod's ephemeralcontainers subresource.

- **imagePullSecrets** ([][LocalObjectReference](#))

*Patch strategy: merge on key name*

ImagePullSecrets is an optional list of references to secrets in the same namespace to use for pulling any of the images used by this PodSpec. If specified, these secrets will be passed to individual puller implementations for them to use. More info: <https://kubernetes.io/docs/concepts/containers/images#specifying-imagepullsecrets-on-a-pod>

- **enableServiceLinks** (boolean)

EnableServiceLinks indicates whether information about services should be injected into pod's environment variables, matching the syntax of Docker links. Optional: Defaults to true.

## • **os** (PodOS)

Specifies the OS of the containers in the pod. Some pod and container fields are restricted if this is set.

If the OS field is set to linux, the following fields must be unset: - securityContext.windowsOptions

If the OS field is set to windows, following fields must be unset: - spec.hostPID - spec.hostIPC - spec.hostUsers - spec.securityContext.seLinuxOptions - spec.securityContext.seccompProfile - spec.securityContext.fsGroup - spec.securityContext.fsGroupChangePolicy - spec.securityContext.sysctl - spec.shareProcessNamespace - spec.securityContext.runAsUser - spec.securityContext.runAsGroup - spec.securityContext.supplementalGroups - spec.containers[].securityContext.seLinuxOptions - spec.containers[].securityContext.seccompProfile - spec.containers[].securityContext.capabilities - spec.containers[].securityContext.readOnlyRootFilesystem - spec.containers[].securityContext.privileged - spec.containers[].securityContext.allowPrivilegeEscalation - spec.containers[].securityContext.procMount - spec.containers[].securityContext.runAsUser - spec.containers[\*].securityContext.runAsGroup

*PodOS defines the OS parameters of a pod.*

- **os.name** (string), required

Name is the name of the operating system. The currently supported values are linux and windows. Additional value may be defined in future and can be one of: <https://github.com/opencontainers/runtime-spec/blob/master/config.md#platform-specific-configuration> Clients should expect to handle additional values and treat unrecognized values in this field as os: null

## Volumes

- **volumes** ([][Volume](#))

*Patch strategies: retainKeys, merge on key name*

List of volumes that can be mounted by containers belonging to the pod. More info: <https://kubernetes.io/docs/concepts/storage/volumes>

## Scheduling

- **nodeSelector** (map[string]string)

NodeSelector is a selector which must be true for the pod to fit on a node. Selector which must match a node's labels for the pod to be scheduled on that node. More info: <https://kubernetes.io/docs/concepts/configuration/assign-pod-node/>

- **nodeName** (string)

nodeName is a request to schedule this pod onto a specific node. If it is non-empty, the scheduler simply schedules this pod onto that node, assuming that it fits resource requirements.

- **affinity** (Affinity)

If specified, the pod's scheduling constraints

*Affinity is a group of affinity scheduling rules.*

- **affinity.nodeName** ([NodeAffinity](#))

Describes node affinity scheduling rules for the pod.

- **affinity.podAffinity** ([PodAffinity](#))

Describes pod affinity scheduling rules (e.g. co-locate this pod in the same node, zone, etc. as some other pod(s)).

- **affinity.podAntiAffinity** ([PodAntiAffinity](#))

Describes pod anti-affinity scheduling rules (e.g. avoid putting this pod in the same node, zone, etc. as some other pod(s)).

- **tolerations** ([]Toleration)

If specified, the pod's tolerations.

*The pod this Toleration is attached to tolerates any taint that matches the triple <key,value,effect> using the matching operator .*

- **tolerations.key** (string)

Key is the taint key that the toleration applies to. Empty means match all taint keys. If the key is empty, operator must be Exists; this combination means to match all values and all keys.

- **tolerations.operator** (string)

Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

- **tolerations.value** (string)

Value is the taint value the toleration matches to. If the operator is Exists, the value should be empty, otherwise just a regular string.

- **tolerations.effect** (string)

Effect indicates the taint effect to match. Empty means match all taint effects. When specified, allowed values are NoSchedule, PreferNoSchedule and NoExecute.

- **tolerations.tolerationSeconds** (int64)

TolerationSeconds represents the period of time the toleration (which must be of effect NoExecute, otherwise this field is ignored) tolerates the taint. By default, it is not set, which means tolerate the taint forever (do not evict). Zero and negative values will be treated as 0 (evict immediately) by the system.

- **schedulerName** (string)

If specified, the pod will be dispatched by specified scheduler. If not specified, the pod will be dispatched by default scheduler.

- **runtimeClassName** (string)

RuntimeClassName refers to a RuntimeClass object in the node.k8s.io group, which should be used to run this pod. If no RuntimeClass resource matches the named class, the pod will not be run. If unset or empty, the "legacy" RuntimeClass will be used, which is an implicit class with an empty definition that uses the default runtime handler. More info: <https://git.k8s.io/enhancements/keps/sig-node/585-runtime-class>

- **priorityClassName** (string)

If specified, indicates the pod's priority. "system-node-critical" and "system-cluster-critical" are two special keywords which indicate the highest priorities with the former being the highest priority. Any other name must be defined by creating a PriorityClass object with that name. If not specified, the pod priority will be default or zero if there is no default.

- **priority** (int32)

The priority value. Various system components use this field to find the priority of the pod. When Priority Admission Controller is enabled, it prevents users from setting this field. The admission controller populates this field from PriorityClassName. The higher the value, the higher the priority.

- **preemptionPolicy** (string)

PreemptionPolicy is the Policy for preempting pods with lower priority. One of Never, PreemptLowerPriority. Defaults to PreemptLowerPriority if unset.

- **topologySpreadConstraints** ([]TopologySpreadConstraint)

*Patch strategy: merge on key topologyKey*

*Map: unique values on keys topologyKey, whenUnsatisfiable will be kept during a merge*

TopologySpreadConstraints describes how a group of pods ought to spread across topology domains. Scheduler will schedule pods in a way which abides by the constraints. All topologySpreadConstraints are ANDed.

*TopologySpreadConstraint specifies how to spread matching pods among the given topology.*

- **topologySpreadConstraints.maxSkew** (int32), required

MaxSkew describes the degree to which pods may be unevenly distributed. When `whenUnsatisfiable=DoNotSchedule`, it is the maximum permitted difference between the number of matching pods in the target topology and the global

minimum. The global minimum is the minimum number of matching pods in an eligible domain or zero if the number of eligible domains is less than MinDomains. For example, in a 3-zone cluster, MaxSkew is set to 1, and pods with the same labelSelector spread as 2/2/1: In this case, the global minimum is 1. | zone1 | zone2 | zone3 || P P | P P | P | - if MaxSkew is 1, incoming pod can only be scheduled to zone3 to become 2/2/2; scheduling it onto zone1(zone2) would make the ActualSkew(3-1) on zone1(zone2) violate MaxSkew(1). - if MaxSkew is 2, incoming pod can be scheduled onto any zone. When whenUnsatisfiable=ScheduleAnyway, it is used to give higher precedence to topologies that satisfy it. It's a required field. Default value is 1 and 0 is not allowed.

- **topologySpreadConstraints.topologyKey** (string), required

TopologyKey is the key of node labels. Nodes that have a label with this key and identical values are considered to be in the same topology. We consider each <key, value> as a "bucket", and try to put balanced number of pods into each bucket. We define a domain as a particular instance of a topology. Also, we define an eligible domain as a domain whose nodes meet the requirements of nodeAffinityPolicy and nodeTaintsPolicy. e.g. If TopologyKey is "kubernetes.io/hostname", each Node is a domain of that topology. And, if TopologyKey is "topology.kubernetes.io/zone", each zone is a domain of that topology. It's a required field.

- **topologySpreadConstraints.whenUnsatisfiable** (string), required

WhenUnsatisfiable indicates how to deal with a pod if it doesn't satisfy the spread constraint. - DoNotSchedule (default) tells the scheduler not to schedule it. - ScheduleAnyway tells the scheduler to schedule the pod in any location, but giving higher precedence to topologies that would help reduce the skew. A constraint is considered "Unsatisfiable" for an incoming pod if and only if every possible node assignment for that pod would violate "MaxSkew" on some topology. For example, in a 3-zone cluster, MaxSkew is set to 1, and pods with the same labelSelector spread as 3/1/1: | zone1 | zone2 | zone3 || P P P | P | P | If WhenUnsatisfiable is set to DoNotSchedule, incoming pod can only be scheduled to zone2(zone3) to become 3/2/1(3/1/2) as ActualSkew(2-1) on zone2(zone3) satisfies MaxSkew(1). In other words, the cluster can still be imbalanced, but scheduler won't make it *more* imbalanced. It's a required field.

- **topologySpreadConstraints.labelSelector** ([LabelSelector](#))

LabelSelector is used to find matching pods. Pods that match this label selector are counted to determine the number of pods in their corresponding topology domain.

- **topologySpreadConstraints.matchLabelKeys** ([]string)

*Atomic: will be replaced during a merge*

MatchLabelKeys is a set of pod label keys to select the pods over which spreading will be calculated. The keys are used to lookup values from the incoming pod labels, those key-value labels are ANDed with labelSelector to select the group of existing pods over which spreading will be calculated for the incoming pod. The same key is forbidden to exist in both MatchLabelKeys and LabelSelector. MatchLabelKeys cannot be set when LabelSelector isn't set. Keys that don't exist in the incoming pod labels will be ignored. A null or empty list means only match against labelSelector.

This is a beta field and requires the MatchLabelKeysInPodTopologySpread feature gate to be enabled (enabled by default).

- **topologySpreadConstraints.minDomains** (int32)

MinDomains indicates a minimum number of eligible domains. When the number of eligible domains with matching topology keys is less than minDomains, Pod Topology Spread treats "global minimum" as 0, and then the calculation of Skew is performed. And when the number of eligible domains with matching topology keys equals or greater than minDomains, this value has no effect on scheduling. As a result, when the number of eligible domains is less than minDomains, scheduler won't schedule more than maxSkew Pods to those domains. If value is nil, the constraint behaves as if MinDomains is equal to 1. Valid values are integers greater than 0. When value is not nil, WhenUnsatisfiable must be DoNotSchedule.

For example, in a 3-zone cluster, MaxSkew is set to 2, MinDomains is set to 5 and pods with the same labelSelector spread as 2/2/2: | zone1 | zone2 | zone3 | | P P | P P | P P | The number of domains is less than 5(MinDomains), so "global minimum" is treated as 0. In this situation, new pod with the same labelSelector cannot be scheduled, because computed skew will be 3(3 - 0) if new Pod is scheduled to any of the three zones, it will violate MaxSkew.

This is a beta field and requires the MinDomainsInPodTopologySpread feature gate to be enabled (enabled by default).

- **topologySpreadConstraints.nodeAffinityPolicy** (string)

NodeAffinityPolicy indicates how we will treat Pod's nodeAffinity/nodeSelector when calculating pod topology spread skew. Options are: - Honor: only nodes matching nodeAffinity/nodeSelector are included in the calculations. - Ignore: nodeAffinity/nodeSelector are ignored. All nodes are included in the calculations.

If this value is nil, the behavior is equivalent to the Honor policy. This is a beta-level feature default enabled by the NodeInclusionPolicyInPodTopologySpread feature flag.

- **topologySpreadConstraints.nodeTaintsPolicy** (string)

NodeTaintsPolicy indicates how we will treat node taints when calculating pod topology spread skew. Options are: - Honor: nodes without taints, along with tainted nodes for which the incoming pod has a toleration, are included. - Ignore: node taints are ignored. All nodes are included.

If this value is nil, the behavior is equivalent to the Ignore policy. This is a beta-level feature default enabled by the NodeInclusionPolicyInPodTopologySpread feature flag.

- **overhead** (map[string][Quantity](#))

Overhead represents the resource overhead associated with running a pod for a given RuntimeClass. This field will be autopopulated at admission time by the RuntimeClass admission controller. If the RuntimeClass admission controller is enabled, overhead must not be set in Pod create requests. The RuntimeClass admission controller will reject Pod create requests which have the overhead already set. If RuntimeClass is configured and

selected in the PodSpec, Overhead will be set to the value defined in the corresponding RuntimeClass, otherwise it will remain unset and treated as zero. More info: <https://git.k8s.io/enhancements/keps/sig-node/688-pod-overhead/README.md>

## Lifecycle

- **restartPolicy** (string)

Restart policy for all containers within the pod. One of Always, OnFailure, Never. In some contexts, only a subset of those values may be permitted. Default to Always. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle/#restart-policy>

- **terminationGracePeriodSeconds** (int64)

Optional duration in seconds the pod needs to terminate gracefully. May be decreased in delete request. Value must be non-negative integer. The value zero indicates stop immediately via the kill signal (no opportunity to shut down). If this value is nil, the default grace period will be used instead. The grace period is the duration in seconds after the processes running in the pod are sent a termination signal and the time when the processes are forcibly halted with a kill signal. Set this value longer than the expected cleanup time for your process. Defaults to 30 seconds.

- **activeDeadlineSeconds** (int64)

Optional duration in seconds the pod may be active on the node relative to StartTime before the system will actively try to mark it failed and kill associated containers. Value must be a positive integer.

- **readinessGates** ([]PodReadinessGate)

If specified, all readiness gates will be evaluated for pod readiness. A pod is ready when all its containers are ready AND all conditions specified in the readiness gates have status equal to "True" More info: <https://git.k8s.io/enhancements/keps/sig-network/580-pod-readiness-gates>

*PodReadinessGate contains the reference to a pod condition*

- **readinessGates.conditionType** (string), required

ConditionType refers to a condition in the pod's condition list with matching type.

## Hostname and Name resolution

- **hostname** (string)

Specifies the hostname of the Pod If not specified, the pod's hostname will be set to a system-defined value.

- **setHostnameAsFQDN** (boolean)

If true the pod's hostname will be configured as the pod's FQDN, rather than the leaf name (the default). In Linux containers, this means setting the FQDN in the hostname field of the kernel (the nodename field of struct utsname). In Windows containers, this means setting the registry value of hostname for the registry key

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters to FQDN. If a pod does not have FQDN, this has no effect. Default to false.

- **subdomain** (string)

If specified, the fully qualified Pod hostname will be "<hostname>.<subdomain>.<pod namespace>.svc.<cluster domain>". If not specified, the pod will not have a domainname at all.

- **hostAliases** ([]HostAlias)

*Patch strategy: merge on key ip*

HostAliases is an optional list of hosts and IPs that will be injected into the pod's hosts file if specified. This is only valid for non-hostNetwork pods.

*HostAlias holds the mapping between IP and hostnames that will be injected as an entry in the pod's hosts file.*

- **hostAliases.hostnames** ([]string)

Hostnames for the above IP address.

- **hostAliases.ip** (string)

IP address of the host file entry.

- **dnsConfig** (PodDNSConfig)

Specifies the DNS parameters of a pod. Parameters specified here will be merged to the generated DNS configuration based on DNSPolicy.

*PodDNSConfig defines the DNS parameters of a pod in addition to those generated from DNSPolicy.*

- **dnsConfig.nameservers** ([]string)

A list of DNS name server IP addresses. This will be appended to the base nameservers generated from DNSPolicy. Duplicated nameservers will be removed.

- **dnsConfig.options** ([]PodDNSConfigOption)

A list of DNS resolver options. This will be merged with the base options generated from DNSPolicy. Duplicated entries will be removed. Resolution options given in Options will override those that appear in the base DNSPolicy.

*PodDNSConfigOption defines DNS resolver options of a pod.*

- **dnsConfig.options.name** (string)

Required.

- **dnsConfig.options.value** (string)

- **dnsConfig.searches** ([]string)

A list of DNS search domains for host-name lookup. This will be appended to the base search paths generated from DNSPolicy. Duplicated search paths will be removed.

- **dnsPolicy** (string)

Set DNS policy for the pod. Defaults to "ClusterFirst". Valid values are 'ClusterFirstWithHostNet', 'ClusterFirst', 'Default' or 'None'. DNS parameters given in DNSConfig will be merged with the policy selected with DNSPolicy. To have DNS options set along with hostNetwork, you have to specify DNS policy explicitly to 'ClusterFirstWithHostNet'.

## Hosts namespaces

- **hostNetwork** (boolean)

Host networking requested for this pod. Use the host's network namespace. If this option is set, the ports that will be used must be specified. Default to false.

- **hostPID** (boolean)

Use the host's pid namespace. Optional: Default to false.

- **hostIPC** (boolean)

Use the host's ipc namespace. Optional: Default to false.

- **shareProcessNamespace** (boolean)

Share a single process namespace between all of the containers in a pod. When this is set containers will be able to view and signal processes from other containers in the same pod, and the first process in each container will not be assigned PID 1. HostPID and ShareProcessNamespace cannot both be set. Optional: Default to false.

## Service account

- **serviceAccountName** (string)

ServiceAccountName is the name of the ServiceAccount to use to run this pod. More info: <https://kubernetes.io/docs/tasks/configure-pod-container/configure-service-account/>

- **automountServiceAccountToken** (boolean)

AutomountServiceAccountToken indicates whether a service account token should be automatically mounted.

## Security context

- **securityContext** (PodSecurityContext)

SecurityContext holds pod-level security attributes and common container settings. Optional: Defaults to empty. See type description for default values of each field.

*PodSecurityContext holds pod-level security attributes and common container settings. Some fields are also present in container.securityContext. Field values of container.securityContext take precedence over field values of PodSecurityContext.*

- **securityContext.runAsUser** (int64)

The UID to run the entrypoint of the container process. Defaults to user specified in image metadata if unspecified. May also be set in SecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence for that container. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.runAsNonRoot** (boolean)

Indicates that the container must run as a non-root user. If true, the Kubelet will validate the image at runtime to ensure that it does not run as UID 0 (root) and fail to start the container if it does. If unset or false, no such validation will be performed. May also be set in SecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

- **securityContext.runAsGroup** (int64)

The GID to run the entrypoint of the container process. Uses runtime default if unset. May also be set in SecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence for that container. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.supplementalGroups** ([]int64)

A list of groups applied to the first process run in each container, in addition to the container's primary GID, the fsGroup (if specified), and group memberships defined in the container image for the uid of the container process. If unspecified, no additional groups are added to any container. Note that group memberships defined in the container image for the uid of the container process are still effective, even if they are not included in this list. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.fsGroup** (int64)

A special supplemental group that applies to all containers in a pod. Some volume types allow the Kubelet to change the ownership of that volume to be owned by the pod:

1. The owning GID will be the FSGroup
2. The setgid bit is set (new files created in the volume will be owned by FSGroup)
3. The permission bits are OR'd with rw-rw----

If unset, the Kubelet will not modify the ownership and permissions of any volume. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.fsGroupChangePolicy** (string)

fsGroupChangePolicy defines behavior of changing ownership and permission of the volume before being exposed inside Pod. This field will only apply to volume types which support fsGroup based ownership(and permissions). It will have no

effect on ephemeral volume types such as: secret, configmaps and emptydir. Valid values are "OnRootMismatch" and "Always". If not specified, "Always" is used. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.seccompProfile** (SeccompProfile)

The seccomp options to use by the containers in this pod. Note that this field cannot be set when spec.os.name is windows.

*SeccompProfile defines a pod/container's seccomp profile settings. Only one profile source may be set.*

- **securityContext.seccompProfile.type** (string), required

type indicates which kind of seccomp profile will be applied. Valid options are:

Localhost - a profile defined in a file on the node should be used.

RuntimeDefault - the container runtime default profile should be used.

Unconfined - no profile should be applied.

- **securityContext.seccompProfile.localhostProfile** (string)

localhostProfile indicates a profile defined in a file on the node should be used. The profile must be preconfigured on the node to work. Must be a descending path, relative to the kubelet's configured seccomp profile location. Must be set if type is "Localhost". Must NOT be set for any other type.

- **securityContext.seLinuxOptions** (SELinuxOptions)

The SELinux context to be applied to all containers. If unspecified, the container runtime will allocate a random SELinux context for each container. May also be set in SecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence for that container. Note that this field cannot be set when spec.os.name is windows.

*SELinuxOptions are the labels to be applied to the container*

- **securityContext.seLinuxOptions.level** (string)

Level is SELinux level label that applies to the container.

- **securityContext.seLinuxOptions.role** (string)

Role is a SELinux role label that applies to the container.

- **securityContext.seLinuxOptions.type** (string)

Type is a SELinux type label that applies to the container.

- **securityContext.seLinuxOptions.user** (string)

User is a SELinux user label that applies to the container.

- **securityContext.sysctls** ([]Sysctl)

Sysctls hold a list of namespaced sysctls used for the pod. Pods with unsupported sysctls (by the container runtime) might fail to launch. Note that this field cannot be set when spec.os.name is windows.

*Sysctl defines a kernel parameter to be set*

- **securityContext.sysctls.name** (string), required

Name of a property to set

- **securityContext.sysctls.value** (string), required

Value of a property to set

- **securityContext.windowsOptions** (WindowsSecurityContextOptions)

The Windows specific settings applied to all containers. If unspecified, the options within a container's SecurityContext will be used. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is linux.

*WindowsSecurityContextOptions contain Windows-specific options and credentials.*

- **securityContext.windowsOptions.gmsaCredentialSpec** (string)

GMSACredentialSpec is where the GMSA admission webhook (<https://github.com/kubernetes-sigs/windows-gmsa>) inlines the contents of the GMSA credential spec named by the GMSACredentialSpecName field.

- **securityContext.windowsOptions.gmsaCredentialSpecName** (string)

GMSACredentialSpecName is the name of the GMSA credential spec to use.

- **securityContext.windowsOptions.hostProcess** (boolean)

HostProcess determines if a container should be run as a 'Host Process' container. All of a Pod's containers must have the same effective HostProcess value (it is not allowed to have a mix of HostProcess containers and non-HostProcess containers). In addition, if HostProcess is true then HostNetwork must also be set to true.

- **securityContext.windowsOptions.runAsUserName** (string)

The UserName in Windows to run the entrypoint of the container process. Defaults to the user specified in image metadata if unspecified. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

## Alpha level

- **hostUsers** (boolean)

Use the host's user namespace. Optional: Default to true. If set to true or not present, the pod will be run in the host user namespace, useful for when the pod needs a feature only available to the host user namespace, such as loading a kernel module with

CAP\_SYS\_MODULE. When set to false, a new users is created for the pod. Setting false is useful for mitigating container breakout vulnerabilities even allowing users to run their containers as root without actually having root privileges on the host. This field is alpha-level and is only honored by servers that enable the UserNamespacesSupport feature.

- **resourceClaims** ([]PodResourceClaim)

*Patch strategies: retainKeys, merge on key name*

*Map: unique values on key name will be kept during a merge*

ResourceClaims defines which ResourceClaims must be allocated and reserved before the Pod is allowed to start. The resources will be made available to those containers which consume them by name.

This is an alpha field and requires enabling the DynamicResourceAllocation feature gate.

This field is immutable.

*PodResourceClaim references exactly one ResourceClaim through a ClaimSource. It adds a name to it that uniquely identifies the ResourceClaim inside the Pod. Containers that need access to the ResourceClaim reference it with this name.*

- **resourceClaims.name** (string), required

Name uniquely identifies this resource claim inside the pod. This must be a DNS\_LABEL.

- **resourceClaims.source** (ClaimSource)

Source describes where to find the ResourceClaim.

\*ClaimSource describes a reference to a ResourceClaim.

Exactly one of these fields should be set. Consumers of this type must treat an empty object as if it has an unknown value.\*

- **resourceClaims.source.resourceClaimName** (string)

ResourceClaimName is the name of a ResourceClaim object in the same namespace as this pod.

- **resourceClaims.source.resourceClaimTemplateName** (string)

ResourceClaimTemplateName is the name of a ResourceClaimTemplate object in the same namespace as this pod.

The template will be used to create a new ResourceClaim, which will be bound to this pod. When this pod is deleted, the ResourceClaim will also be deleted. The pod name and resource name, along with a generated component, will be used to form a unique name for the ResourceClaim, which will be recorded in pod.status.resourceClaimStatuses.

This field is immutable and no changes will be made to the corresponding ResourceClaim by the control plane after creating the ResourceClaim.

• **schedulingGates** ([]PodSchedulingGate)

*Patch strategy: merge on key name*

*Map: unique values on key name will be kept during a merge*

SchedulingGates is an opaque list of values that if specified will block scheduling the pod. If schedulingGates is not empty, the pod will stay in the SchedulingGated state and the scheduler will not attempt to schedule the pod.

SchedulingGates can only be set at pod creation time, and be removed only afterwards.

This is a beta feature enabled by the PodSchedulingReadiness feature gate.

*PodSchedulingGate is associated to a Pod to guard its scheduling.*

- **schedulingGates.name** (string), required

Name of the scheduling gate. Each scheduling gate must have a unique name field.

## Deprecated

- **serviceAccount** (string)

DeprecatedServiceAccount is a depreciated alias for ServiceAccountName. Deprecated: Use serviceAccountName instead.

## Container

A single application container that you want to run within a pod.

---

- **name** (string), required

Name of the container specified as a DNS\_LABEL. Each container in a pod must have a unique name (DNS\_LABEL). Cannot be updated.

## Image

- **image** (string)

Container image name. More info: <https://kubernetes.io/docs/concepts/containers/images>  
This field is optional to allow higher level config management to default or override container images in workload controllers like Deployments and StatefulSets.

- **imagePullPolicy** (string)

Image pull policy. One of Always, Never, IfNotPresent. Defaults to Always if :latest tag is specified, or IfNotPresent otherwise. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/containers/images#updating-images>

## Entrypoint

- **command** ([]string)

Entrypoint array. Not executed within a shell. The container image's ENTRYPOINT is used if this is not provided. Variable references \$(VAR\_NAME) are expanded using the container's environment. If a variable cannot be resolved, the reference in the input string will be unchanged. Double \$\$ are reduced to a single \$, which allows for escaping the \$(VAR\_NAME) syntax: i.e. "\$\$(VAR\_NAME)" will produce the string literal "\$ (VAR\_NAME)". Escaped references will never be expanded, regardless of whether the variable exists or not. Cannot be updated. More info: <https://kubernetes.io/docs/tasks/inject-data-application/define-command-argument-container/#running-a-command-in-a-shell>

- **args** ([]string)

Arguments to the entrypoint. The container image's CMD is used if this is not provided. Variable references \$(VAR\_NAME) are expanded using the container's environment. If a variable cannot be resolved, the reference in the input string will be unchanged. Double \$ are reduced to a single \$, which allows for escaping the \$(VAR\_NAME) syntax: i.e. "\$\$ (VAR\_NAME)" will produce the string literal "\$(VAR\_NAME)". Escaped references will never be expanded, regardless of whether the variable exists or not. Cannot be updated. More info: <https://kubernetes.io/docs/tasks/inject-data-application/define-command-argument-container/#running-a-command-in-a-shell>

- **workingDir** (string)

Container's working directory. If not specified, the container runtime's default will be used, which might be configured in the container image. Cannot be updated.

## Ports

- **ports** ([]ContainerPort)

*Patch strategy: merge on key containerPort*

*Map: unique values on keys containerPort, protocol will be kept during a merge*

List of ports to expose from the container. Not specifying a port here DOES NOT prevent that port from being exposed. Any port which is listening on the default "0.0.0.0" address inside a container will be accessible from the network. Modifying this array with strategic merge patch may corrupt the data. For more information See <https://github.com/kubernetes/kubernetes/issues/108255>. Cannot be updated.

*ContainerPort represents a network port in a single container.*

- **ports.containerPort** (int32), required

Number of port to expose on the pod's IP address. This must be a valid port number, 0 < x < 65536.

- **ports.hostIP** (string)

What host IP to bind the external port to.

**ports.hostPort** (int32)

- Number of port to expose on the host. If specified, this must be a valid port number,  $0 < x < 65536$ . If HostNetwork is specified, this must match ContainerPort. Most containers do not need this.

- **ports.name** (string)

If specified, this must be an IANA\_SVC\_NAME and unique within the pod. Each named port in a pod must have a unique name. Name for the port that can be referred to by services.

- **ports.protocol** (string)

Protocol for port. Must be UDP, TCP, or SCTP. Defaults to "TCP".

## Environment variables

- **env** ([]EnvVar)

*Patch strategy: merge on key name*

List of environment variables to set in the container. Cannot be updated.

*EnvVar represents an environment variable present in a Container.*

- **env.name** (string), required

Name of the environment variable. Must be a C\_IDENTIFIER.

- **env.value** (string)

Variable references  $\$(VAR\_NAME)$  are expanded using the previously defined environment variables in the container and any service environment variables. If a variable cannot be resolved, the reference in the input string will be unchanged. Double  $\$$  are reduced to a single  $\$$ , which allows for escaping the  $\$(VAR\_NAME)$  syntax: i.e.  $\$\$(VAR\_NAME)$  will produce the string literal  $\$(VAR\_NAME)$ . Escaped references will never be expanded, regardless of whether the variable exists or not. Defaults to "".

- **env.valueFrom** (EnvVarSource)

Source for the environment variable's value. Cannot be used if value is not empty.

*EnvVarSource represents a source for the value of an EnvVar.*

- **env.valueFrom.configMapKeyRef** (ConfigMapKeySelector)

Selects a key of a ConfigMap.

*Selects a key from a ConfigMap.*

- **env.valueFrom.configMapKeyRef.key** (string), required

The key to select.

▪ **env.valueFrom.configMapKeyRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

▪ **env.valueFrom.configMapKeyRef.optional** (boolean)

Specify whether the ConfigMap or its key must be defined

▪ **env.valueFrom.fieldRef** ([ObjectFieldSelector](#))

Selects a field of the pod: supports metadata.name, metadata.namespace, metadata.labels['\<KEY>'], metadata.annotations['\<KEY>'], spec.nodeName, spec.serviceAccountName, status.hostIP, status.podIP, status.podIPs.

▪ **env.valueFrom.resourceFieldRef** ([ResourceFieldSelector](#))

Selects a resource of the container: only resources limits and requests (limits.cpu, limits.memory, limits.ephemeral-storage, requests.cpu, requests.memory and requests.ephemeral-storage) are currently supported.

▪ **env.valueFrom.secretKeyRef** (SecretKeySelector)

Selects a key of a secret in the pod's namespace

*SecretKeySelector selects a key of a Secret.*

▪ **env.valueFrom.secretKeyRef.key** (string), required

The key of the secret to select from. Must be a valid secret key.

▪ **env.valueFrom.secretKeyRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

▪ **env.valueFrom.secretKeyRef.optional** (boolean)

Specify whether the Secret or its key must be defined

• **envFrom** ([]EnvFromSource)

List of sources to populate environment variables in the container. The keys defined within a source must be a C\_IDENTIFIER. All invalid keys will be reported as an event when the container is starting. When a key exists in multiple sources, the value associated with the last source will take precedence. Values defined by an Env with a duplicate key will take precedence. Cannot be updated.

*EnvFromSource represents the source of a set of ConfigMaps*

◦ **envFrom.configMapRef** (ConfigMapEnvSource)

The ConfigMap to select from

\*ConfigMapEnvSource selects a ConfigMap to populate the environment variables with.

The contents of the target ConfigMap's Data field will represent the key-value pairs as environment variables.\*

- **envFrom.configMapRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **envFrom.configMapRef.optional** (boolean)

Specify whether the ConfigMap must be defined

- **envFrom.prefix** (string)

An optional identifier to prepend to each key in the ConfigMap. Must be a C\_IDENTIFIER.

- **envFrom.secretRef** (SecretEnvSource)

The Secret to select from

\*SecretEnvSource selects a Secret to populate the environment variables with.

The contents of the target Secret's Data field will represent the key-value pairs as environment variables.\*

- **envFrom.secretRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **envFrom.secretRef.optional** (boolean)

Specify whether the Secret must be defined

## Volumes

- **volumeMounts** ([]VolumeMount)

*Patch strategy: merge on key mountPath*

Pod volumes to mount into the container's filesystem. Cannot be updated.

*VolumeMount describes a mounting of a Volume within a container.*

- **volumeMounts.mountPath** (string), required

Path within the container at which the volume should be mounted. Must not contain ':

- **volumeMounts.name** (string), required

This must match the Name of a Volume.

- **volumeMounts.mountPropagation** (string)

mountPropagation determines how mounts are propagated from the host to container and the other way around. When not set, MountPropagationNone is used. This field is beta in 1.10.

- **volumeMounts.readOnly** (boolean)

Mounted read-only if true, read-write otherwise (false or unspecified). Defaults to false.

- **volumeMounts.subPath** (string)

Path within the volume from which the container's volume should be mounted. Defaults to "" (volume's root).

- **volumeMounts.subPathExpr** (string)

Expanded path within the volume from which the container's volume should be mounted. Behaves similarly to SubPath but environment variable references \$ (VAR\_NAME) are expanded using the container's environment. Defaults to "" (volume's root). SubPathExpr and SubPath are mutually exclusive.

- **volumeDevices** ([]VolumeDevice)

*Patch strategy: merge on key devicePath*

volumeDevices is the list of block devices to be used by the container.

*volumeDevice describes a mapping of a raw block device within a container.*

- **volumeDevices.devicePath** (string), required

devicePath is the path inside of the container that the device will be mapped to.

- **volumeDevices.name** (string), required

name must match the name of a persistentVolumeClaim in the pod

## Resources

- **resources** (ResourceRequirements)

Compute Resources required by this container. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

*ResourceRequirements describes the compute resource requirements.*

- **resources.claims** ([]ResourceClaim)

*Map: unique values on key name will be kept during a merge*

Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container.

This is an alpha field and requires enabling the DynamicResourceAllocation feature gate.

This field is immutable. It can only be set for containers.

*ResourceClaim references one entry in PodSpec.ResourceClaims.*

- **resources.claims.name** (string), required

Name must match the name of one entry in pod.spec.resourceClaims of the Pod where this field is used. It makes that resource available inside a container.

- **resources.limits** (map[string][Quantity](https://kubernetes.io/docs/concepts/containers/quantity/))

Limits describes the maximum amount of compute resources allowed. More info: <https://kubernetes.io/docs/concepts/containers/quantity/>

- **resources.requests** (map[string][Quantity](https://kubernetes.io/docs/concepts/containers/quantity/))

Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: <https://kubernetes.io/docs/concepts/containers/quantity/>

- **resizePolicy** ([]ContainerResizePolicy)

*Atomic: will be replaced during a merge*

Resources resize policy for the container.

*ContainerResizePolicy represents resource resize policy for the container.*

- **resizePolicy.resourceName** (string), required

Name of the resource to which this resource resize policy applies. Supported values: cpu, memory.

- **resizePolicy.restartPolicy** (string), required

Restart policy to apply when specified resource is resized. If not specified, it defaults to NotRequired.

## Lifecycle

- **lifecycle** (Lifecycle)

Actions that the management system should take in response to container lifecycle events. Cannot be updated.

*Lifecycle describes actions that the management system should take in response to container lifecycle events. For the PostStart and PreStop lifecycle handlers, management of the container blocks until the action is complete, unless the container process fails, in which case the handler is aborted.*

- **lifecycle.postStart** ([LifecycleHandler](https://kubernetes.io/docs/concepts/containers/lifecycle-hooks/))

PostStart is called immediately after a container is created. If the handler fails, the container is terminated and restarted according to its restart policy. Other management of the container blocks until the hook completes. More info: <https://kubernetes.io/docs/concepts/containers/container-lifecycle-hooks/#container-hooks>

- **lifecycle.preStop** ([LifecycleHandler](#))

PreStop is called immediately before a container is terminated due to an API request or management event such as liveness/startup probe failure, preemption, resource contention, etc. The handler is not called if the container crashes or exits. The Pod's termination grace period countdown begins before the PreStop hook is executed. Regardless of the outcome of the handler, the container will eventually terminate within the Pod's termination grace period (unless delayed by finalizers). Other management of the container blocks until the hook completes or until the termination grace period is reached. More info: <https://kubernetes.io/docs/concepts/containers/container-lifecycle-hooks/#container-hooks>

- **terminationMessagePath** (string)

Optional: Path at which the file to which the container's termination message will be written is mounted into the container's filesystem. Message written is intended to be brief final status, such as an assertion failure message. Will be truncated by the node if greater than 4096 bytes. The total message length across all containers will be limited to 12kb. Defaults to /dev/termination-log. Cannot be updated.

- **terminationMessagePolicy** (string)

Indicate how the termination message should be populated. File will use the contents of terminationMessagePath to populate the container status message on both success and failure. FallbackToLogsOnError will use the last chunk of container log output if the termination message file is empty and the container exited with an error. The log output is limited to 2048 bytes or 80 lines, whichever is smaller. Defaults to File. Cannot be updated.

- **livenessProbe** ([Probe](#))

Periodic probe of container liveness. Container will be restarted if the probe fails. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#container-probes>

- **readinessProbe** ([Probe](#))

Periodic probe of container service readiness. Container will be removed from service endpoints if the probe fails. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#container-probes>

- **startupProbe** ([Probe](#))

StartupProbe indicates that the Pod has successfully initialized. If specified, no other probes are executed until this completes successfully. If this probe fails, the Pod will be restarted, just as if the livenessProbe failed. This can be used to provide different probe parameters at the beginning of a Pod's lifecycle, when it might take a long time to load

data or warm a cache, than during steady-state operation. This cannot be updated. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#container-probes>

- **restartPolicy** (string)

RestartPolicy defines the restart behavior of individual containers in a pod. This field may only be set for init containers, and the only allowed value is "Always". For non-init containers or when this field is not specified, the restart behavior is defined by the Pod's restart policy and the container type. Setting the RestartPolicy as "Always" for the init container will have the following effect: this init container will be continually restarted on exit until all regular containers have terminated. Once all regular containers have completed, all init containers with restartPolicy "Always" will be shut down. This lifecycle differs from normal init containers and is often referred to as a "sidecar" container. Although this init container still starts in the init container sequence, it does not wait for the container to complete before proceeding to the next init container. Instead, the next init container starts immediately after this init container is started, or after any startupProbe has successfully completed.

## Security Context

- **securityContext** (SecurityContext)

SecurityContext defines the security options the container should be run with. If set, the fields of SecurityContext override the equivalent fields of PodSecurityContext. More info: <https://kubernetes.io/docs/tasks/configure-pod-container/security-context/>

*SecurityContext holds security configuration that will be applied to a container. Some fields are present in both SecurityContext and PodSecurityContext. When both are set, the values in SecurityContext take precedence.*

- **securityContext.runAsUser** (int64)

The UID to run the entrypoint of the container process. Defaults to user specified in image metadata if unspecified. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.runAsNonRoot** (boolean)

Indicates that the container must run as a non-root user. If true, the Kubelet will validate the image at runtime to ensure that it does not run as UID 0 (root) and fail to start the container if it does. If unset or false, no such validation will be performed. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

- **securityContext.runAsGroup** (int64)

The GID to run the entrypoint of the container process. Uses runtime default if unset. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.readOnlyRootFilesystem** (boolean)

Whether this container has a read-only root filesystem. Default is false. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.procMount** (string)

procMount denotes the type of proc mount to use for the containers. The default is DefaultProcMount which uses the container runtime defaults for readonly paths and masked paths. This requires the ProcMountType feature flag to be enabled. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.privileged** (boolean)

Run container in privileged mode. Processes in privileged containers are essentially equivalent to root on the host. Defaults to false. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.allowPrivilegeEscalation** (boolean)

AllowPrivilegeEscalation controls whether a process can gain more privileges than its parent process. This bool directly controls if the no\_new\_privs flag will be set on the container process. AllowPrivilegeEscalation is true always when the container is: 1) run as Privileged 2) has CAP\_SYS\_ADMIN Note that this field cannot be set when spec.os.name is windows.

- **securityContext.capabilities** (Capabilities)

The capabilities to add/drop when running containers. Defaults to the default set of capabilities granted by the container runtime. Note that this field cannot be set when spec.os.name is windows.

*Adds and removes POSIX capabilities from running containers.*

- **securityContext.capabilities.add** ([]string)

Added capabilities

- **securityContext.capabilities.drop** ([]string)

Removed capabilities

- **securityContext.seccompProfile** (SeccompProfile)

The seccomp options to use by this container. If seccomp options are provided at both the pod & container level, the container options override the pod options. Note that this field cannot be set when spec.os.name is windows.

*SeccompProfile defines a pod/container's seccomp profile settings. Only one profile source may be set.*

- **securityContext.seccompProfile.type** (string), required

type indicates which kind of seccomp profile will be applied. Valid options are:

Localhost - a profile defined in a file on the node should be used.  
RuntimeDefault - the container runtime default profile should be used.  
Unconfined - no profile should be applied.

- **securityContext.seccompProfile.localhostProfile** (string)

localhostProfile indicates a profile defined in a file on the node should be used. The profile must be preconfigured on the node to work. Must be a descending path, relative to the kubelet's configured seccomp profile location. Must be set if type is "Localhost". Must NOT be set for any other type.

- **securityContext.seLinuxOptions** (SELinuxOptions)

The SELinux context to be applied to the container. If unspecified, the container runtime will allocate a random SELinux context for each container. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

*SELinuxOptions are the labels to be applied to the container*

- **securityContext.seLinuxOptions.level** (string)

Level is SELinux level label that applies to the container.

- **securityContext.seLinuxOptions.role** (string)

Role is a SELinux role label that applies to the container.

- **securityContext.seLinuxOptions.type** (string)

Type is a SELinux type label that applies to the container.

- **securityContext.seLinuxOptions.user** (string)

User is a SELinux user label that applies to the container.

- **securityContext.windowsOptions** (WindowsSecurityContextOptions)

The Windows specific settings applied to all containers. If unspecified, the options from the PodSecurityContext will be used. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is linux.

*WindowsSecurityContextOptions contain Windows-specific options and credentials.*

- **securityContext.windowsOptions.gmsaCredentialSpec** (string)

GMSACredentialSpec is where the GMSA admission webhook (<https://github.com/kubernetes-sigs/windows-gmsa>) inlines the contents of the GMSA credential spec named by the GMSACredentialSpecName field.

- **securityContext.windowsOptions.gmsaCredentialSpecName** (string)

GMSACredentialSpecName is the name of the GMSA credential spec to use.

- **securityContext.windowsOptions.hostProcess** (boolean)

HostProcess determines if a container should be run as a 'Host Process' container. All of a Pod's containers must have the same effective HostProcess value (it is not allowed to have a mix of HostProcess containers and non-HostProcess containers). In addition, if HostProcess is true then HostNetwork must also be set to true.

- **securityContext.windowsOptions.runAsUserName** (string)

The UserName in Windows to run the entrypoint of the container process. Defaults to the user specified in image metadata if unspecified. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

## Debugging

- **stdin** (boolean)

Whether this container should allocate a buffer for stdin in the container runtime. If this is not set, reads from stdin in the container will always result in EOF. Default is false.

- **stdinOnce** (boolean)

Whether the container runtime should close the stdin channel after it has been opened by a single attach. When stdin is true the stdin stream will remain open across multiple attach sessions. If stdinOnce is set to true, stdin is opened on container start, is empty until the first client attaches to stdin, and then remains open and accepts data until the client disconnects, at which time stdin is closed and remains closed until the container is restarted. If this flag is false, a container processes that reads from stdin will never receive an EOF. Default is false

- **tty** (boolean)

Whether this container should allocate a TTY for itself, also requires 'stdin' to be true. Default is false.

## EphemeralContainer

An EphemeralContainer is a temporary container that you may add to an existing Pod for user-initiated activities such as debugging. Ephemeral containers have no resource or scheduling guarantees, and they will not be restarted when they exit or when a Pod is removed or restarted. The kubelet may evict a Pod if an ephemeral container causes the Pod to exceed its resource allocation.

To add an ephemeral container, use the ephemeralcontainers subresource of an existing Pod. Ephemeral containers may not be removed or restarted.

---

- **name** (string), required

Name of the ephemeral container specified as a DNS\_LABEL. This name must be unique among all containers, init containers and ephemeral containers.

- **targetContainerName** (string)

If set, the name of the container from PodSpec that this ephemeral container targets. The ephemeral container will be run in the namespaces (IPC, PID, etc) of this container. If not set then the ephemeral container uses the namespaces configured in the Pod spec.

The container runtime must implement support for this feature. If the runtime does not support namespace targeting then the result of setting this field is undefined.

## Image

- **image** (string)

Container image name. More info: <https://kubernetes.io/docs/concepts/containers/images>

- **imagePullPolicy** (string)

Image pull policy. One of Always, Never, IfNotPresent. Defaults to Always if :latest tag is specified, or IfNotPresent otherwise. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/containers/images#updating-images>

## Entrypoint

- **command** ([]string)

Entrypoint array. Not executed within a shell. The image's ENTRYPOINT is used if this is not provided. Variable references \$(VAR\_NAME) are expanded using the container's environment. If a variable cannot be resolved, the reference in the input string will be unchanged. Double \$\$ are reduced to a single \$, which allows for escaping the \$(VAR\_NAME) syntax: i.e. "\$\$(VAR\_NAME)" will produce the string literal "\$ (VAR\_NAME)". Escaped references will never be expanded, regardless of whether the variable exists or not. Cannot be updated. More info: <https://kubernetes.io/docs/tasks/inject-data-application/define-command-argument-container/#running-a-command-in-a-shell>

- **args** ([]string)

Arguments to the entrypoint. The image's CMD is used if this is not provided. Variable references \$(VAR\_NAME) are expanded using the container's environment. If a variable cannot be resolved, the reference in the input string will be unchanged. Double \$\$ are reduced to a single \$, which allows for escaping the \$(VAR\_NAME) syntax: i.e. "\$\$(VAR\_NAME)" will produce the string literal "\$(VAR\_NAME)". Escaped references will never be expanded, regardless of whether the variable exists or not. Cannot be updated. More info: <https://kubernetes.io/docs/tasks/inject-data-application/define-command-argument-container/#running-a-command-in-a-shell>

- **workingDir** (string)

Container's working directory. If not specified, the container runtime's default will be used, which might be configured in the container image. Cannot be updated.

## Environment variables

- **env** ([]EnvVar)

*Patch strategy: merge on key name*

List of environment variables to set in the container. Cannot be updated.

*EnvVar represents an environment variable present in a Container.*

- **env.name** (string), required

Name of the environment variable. Must be a C\_IDENTIFIER.

- **env.value** (string)

Variable references \$(VAR\_NAME) are expanded using the previously defined environment variables in the container and any service environment variables. If a variable cannot be resolved, the reference in the input string will be unchanged. Double \$\$ are reduced to a single \$, which allows for escaping the \$(VAR\_NAME) syntax: i.e. "\$\$(VAR\_NAME)" will produce the string literal "\$(VAR\_NAME)". Escaped references will never be expanded, regardless of whether the variable exists or not. Defaults to "".

- **env.valueFrom** (EnvVarSource)

Source for the environment variable's value. Cannot be used if value is not empty.

*EnvVarSource represents a source for the value of an EnvVar.*

- **env.valueFrom.configMapKeyRef** (ConfigMapKeySelector)

Selects a key of a ConfigMap.

*Selects a key from a ConfigMap.*

- **env.valueFrom.configMapKeyRef.key** (string), required

The key to select.

- **env.valueFrom.configMapKeyRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **env.valueFrom.configMapKeyRef.optional** (boolean)

Specify whether the ConfigMap or its key must be defined

- **env.valueFrom.fieldRef** ([ObjectFieldSelector](#))

Selects a field of the pod: supports metadata.name, metadata.namespace, metadata.labels['<KEY>'], metadata.annotations['<KEY>'], spec.nodeName, spec.serviceAccountName, status.hostIP, status.podIP, status.podIPs.

▪ **env.valueFrom.resourceFieldRef** ([ResourceFieldSelector](#))

Selects a resource of the container: only resources limits and requests (limits.cpu, limits.memory, limits.ephemeral-storage, requests.cpu, requests.memory and requests.ephemeral-storage) are currently supported.

▪ **env.valueFrom.secretKeyRef** (SecretKeySelector)

Selects a key of a secret in the pod's namespace

*SecretKeySelector selects a key of a Secret.*

▪ **env.valueFrom.secretKeyRef.key** (string), required

The key of the secret to select from. Must be a valid secret key.

▪ **env.valueFrom.secretKeyRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

▪ **env.valueFrom.secretKeyRef.optional** (boolean)

Specify whether the Secret or its key must be defined

• **envFrom** ([]EnvFromSource)

List of sources to populate environment variables in the container. The keys defined within a source must be a C\_IDENTIFIER. All invalid keys will be reported as an event when the container is starting. When a key exists in multiple sources, the value associated with the last source will take precedence. Values defined by an Env with a duplicate key will take precedence. Cannot be updated.

*EnvFromSource represents the source of a set of ConfigMaps*

◦ **envFrom.configMapRef** (ConfigMapEnvSource)

The ConfigMap to select from

\*ConfigMapEnvSource selects a ConfigMap to populate the environment variables with.

The contents of the target ConfigMap's Data field will represent the key-value pairs as environment variables.\*

▪ **envFrom.configMapRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

▪ **envFrom.configMapRef.optional** (boolean)

Specify whether the ConfigMap must be defined

◦ **envFrom.prefix** (string)

An optional identifier to prepend to each key in the ConfigMap. Must be a C\_IDENTIFIER.

- **envFrom.secretRef** (SecretEnvSource)

The Secret to select from

\*SecretEnvSource selects a Secret to populate the environment variables with.

The contents of the target Secret's Data field will represent the key-value pairs as environment variables.\*

- **envFrom.secretRef.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **envFrom.secretRef.optional** (boolean)

Specify whether the Secret must be defined

## Volumes

- **volumeMounts** ([]VolumeMount)

*Patch strategy: merge on key mountPath*

Pod volumes to mount into the container's filesystem. Subpath mounts are not allowed for ephemeral containers. Cannot be updated.

*VolumeMount describes a mounting of a Volume within a container.*

- **volumeMounts.mountPath** (string), required

Path within the container at which the volume should be mounted. Must not contain ':

- **volumeMounts.name** (string), required

This must match the Name of a Volume.

- **volumeMounts.mountPropagation** (string)

mountPropagation determines how mounts are propagated from the host to container and the other way around. When not set, MountPropagationNone is used. This field is beta in 1.10.

- **volumeMounts.readOnly** (boolean)

Mounted read-only if true, read-write otherwise (false or unspecified). Defaults to false.

- **volumeMounts.subPath** (string)

Path within the volume from which the container's volume should be mounted. Defaults to "" (volume's root).

- **volumeMounts.subPathExpr** (string)

Expanded path within the volume from which the container's volume should be mounted. Behaves similarly to SubPath but environment variable references \$ (VAR\_NAME) are expanded using the container's environment. Defaults to "" (volume's root). SubPathExpr and SubPath are mutually exclusive.

- **volumeDevices** ([]VolumeDevice)

*Patch strategy: merge on key devicePath*

volumeDevices is the list of block devices to be used by the container.

*volumeDevice describes a mapping of a raw block device within a container.*

- **volumeDevices.devicePath** (string), required

devicePath is the path inside of the container that the device will be mapped to.

- **volumeDevices.name** (string), required

name must match the name of a persistentVolumeClaim in the pod

## Resources

- **resizePolicy** ([]ContainerResizePolicy)

*Atomic: will be replaced during a merge*

Resources resize policy for the container.

*ContainerResizePolicy represents resource resize policy for the container.*

- **resizePolicy.resourceName** (string), required

Name of the resource to which this resource resize policy applies. Supported values: cpu, memory.

- **resizePolicy.restartPolicy** (string), required

Restart policy to apply when specified resource is resized. If not specified, it defaults to NotRequired.

## Lifecycle

- **terminationMessagePath** (string)

Optional: Path at which the file to which the container's termination message will be written is mounted into the container's filesystem. Message written is intended to be brief final status, such as an assertion failure message. Will be truncated by the node if greater than 4096 bytes. The total message length across all containers will be limited to 12kb. Defaults to /dev/termination-log. Cannot be updated.

- **terminationMessagePolicy** (string)

Indicate how the termination message should be populated. File will use the contents of terminationMessagePath to populate the container status message on both success and failure. FallbackToLogsOnError will use the last chunk of container log output if the termination message file is empty and the container exited with an error. The log output is limited to 2048 bytes or 80 lines, whichever is smaller. Defaults to File. Cannot be updated.

- **restartPolicy** (string)

Restart policy for the container to manage the restart behavior of each container within a pod. This may only be set for init containers. You cannot set this field on ephemeral containers.

## Debugging

- **stdin** (boolean)

Whether this container should allocate a buffer for stdin in the container runtime. If this is not set, reads from stdin in the container will always result in EOF. Default is false.

- **stdinOnce** (boolean)

Whether the container runtime should close the stdin channel after it has been opened by a single attach. When stdin is true the stdin stream will remain open across multiple attach sessions. If stdinOnce is set to true, stdin is opened on container start, is empty until the first client attaches to stdin, and then remains open and accepts data until the client disconnects, at which time stdin is closed and remains closed until the container is restarted. If this flag is false, a container processes that reads from stdin will never receive an EOF. Default is false

- **tty** (boolean)

Whether this container should allocate a TTY for itself, also requires 'stdin' to be true. Default is false.

## Security context

- **securityContext** (SecurityContext)

Optional: SecurityContext defines the security options the ephemeral container should be run with. If set, the fields of SecurityContext override the equivalent fields of PodSecurityContext.

*SecurityContext holds security configuration that will be applied to a container. Some fields are present in both SecurityContext and PodSecurityContext. When both are set, the values in SecurityContext take precedence.*

- **securityContext.runAsUser** (int64)

The UID to run the entrypoint of the container process. Defaults to user specified in image metadata if unspecified. May also be set in PodSecurityContext. If set in both

SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.runAsNonRoot** (boolean)

Indicates that the container must run as a non-root user. If true, the Kubelet will validate the image at runtime to ensure that it does not run as UID 0 (root) and fail to start the container if it does. If unset or false, no such validation will be performed. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

- **securityContext.runAsGroup** (int64)

The GID to run the entrypoint of the container process. Uses runtime default if unset. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.readOnlyRootFilesystem** (boolean)

Whether this container has a read-only root filesystem. Default is false. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.procMount** (string)

procMount denotes the type of proc mount to use for the containers. The default is DefaultProcMount which uses the container runtime defaults for readonly paths and masked paths. This requires the ProcMountType feature flag to be enabled. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.privileged** (boolean)

Run container in privileged mode. Processes in privileged containers are essentially equivalent to root on the host. Defaults to false. Note that this field cannot be set when spec.os.name is windows.

- **securityContext.allowPrivilegeEscalation** (boolean)

AllowPrivilegeEscalation controls whether a process can gain more privileges than its parent process. This bool directly controls if the no\_new\_privs flag will be set on the container process. AllowPrivilegeEscalation is true always when the container is: 1) run as Privileged 2) has CAP\_SYS\_ADMIN Note that this field cannot be set when spec.os.name is windows.

- **securityContext.capabilities** (Capabilities)

The capabilities to add/drop when running containers. Defaults to the default set of capabilities granted by the container runtime. Note that this field cannot be set when spec.os.name is windows.

*Adds and removes POSIX capabilities from running containers.*

- **securityContext.capabilities.add** ([]string)

Added capabilities

- **securityContext.capabilities.drop** ([]string)

- Removed capabilities

- **securityContext.seccompProfile** (SeccompProfile)

The seccomp options to use by this container. If seccomp options are provided at both the pod & container level, the container options override the pod options. Note that this field cannot be set when spec.os.name is windows.

*SeccompProfile defines a pod/container's seccomp profile settings. Only one profile source may be set.*

- **securityContext.seccompProfile.type** (string), required

- type indicates which kind of seccomp profile will be applied. Valid options are:

- Localhost - a profile defined in a file on the node should be used.

- RuntimeDefault - the container runtime default profile should be used.

- Unconfined - no profile should be applied.

- **securityContext.seccompProfile.localhostProfile** (string)

- localhostProfile indicates a profile defined in a file on the node should be used. The profile must be preconfigured on the node to work. Must be a descending path, relative to the kubelet's configured seccomp profile location. Must be set if type is "Localhost". Must NOT be set for any other type.

- **securityContext.seLinuxOptions** (SELinuxOptions)

The SELinux context to be applied to the container. If unspecified, the container runtime will allocate a random SELinux context for each container. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is windows.

*SELinuxOptions are the labels to be applied to the container*

- **securityContext.seLinuxOptions.level** (string)

- Level is SELinux level label that applies to the container.

- **securityContext.seLinuxOptions.role** (string)

- Role is a SELinux role label that applies to the container.

- **securityContext.seLinuxOptions.type** (string)

- Type is a SELinux type label that applies to the container.

- **securityContext.seLinuxOptions.user** (string)

- User is a SELinux user label that applies to the container.

**securityContext.windowsOptions** (WindowsSecurityContextOptions)

◦

The Windows specific settings applied to all containers. If unspecified, the options from the PodSecurityContext will be used. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence. Note that this field cannot be set when spec.os.name is linux.

*WindowsSecurityContextOptions contain Windows-specific options and credentials.*

▪ **securityContext.windowsOptions.gmsaCredentialSpec** (string)

GMSACredentialSpec is where the GMSA admission webhook (<https://github.com/kubernetes-sigs/windows-gmsa>) inlines the contents of the GMSA credential spec named by the GMSACredentialSpecName field.

▪ **securityContext.windowsOptions.gmsaCredentialSpecName** (string)

GMSACredentialSpecName is the name of the GMSA credential spec to use.

▪ **securityContext.windowsOptions.hostProcess** (boolean)

HostProcess determines if a container should be run as a 'Host Process' container. All of a Pod's containers must have the same effective HostProcess value (it is not allowed to have a mix of HostProcess containers and non-HostProcess containers). In addition, if HostProcess is true then HostNetwork must also be set to true.

▪ **securityContext.windowsOptions.runAsUserName** (string)

The UserName in Windows to run the entrypoint of the container process. Defaults to the user specified in image metadata if unspecified. May also be set in PodSecurityContext. If set in both SecurityContext and PodSecurityContext, the value specified in SecurityContext takes precedence.

## Not allowed

• **ports** ([]ContainerPort)

*Patch strategy: merge on key containerPort*

*Map: unique values on keys containerPort, protocol will be kept during a merge*

Ports are not allowed for ephemeral containers.

*ContainerPort represents a network port in a single container.*

◦ **ports.containerPort** (int32), required

Number of port to expose on the pod's IP address. This must be a valid port number,  $0 < x < 65536$ .

◦ **ports.hostIP** (string)

What host IP to bind the external port to.

**ports.hostPort** (int32)

- Number of port to expose on the host. If specified, this must be a valid port number,  $0 < x < 65536$ . If HostNetwork is specified, this must match ContainerPort. Most containers do not need this.

- **ports.name** (string)

If specified, this must be an IANA\_SVC\_NAME and unique within the pod. Each named port in a pod must have a unique name. Name for the port that can be referred to by services.

- **ports.protocol** (string)

Protocol for port. Must be UDP, TCP, or SCTP. Defaults to "TCP".

- **resources** (ResourceRequirements)

Resources are not allowed for ephemeral containers. Ephemeral containers use spare resources already allocated to the pod.

*ResourceRequirements describes the compute resource requirements.*

- **resources.claims** ([]ResourceClaim)

*Map: unique values on key name will be kept during a merge*

Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container.

This is an alpha field and requires enabling the DynamicResourceAllocation feature gate.

This field is immutable. It can only be set for containers.

*ResourceClaim references one entry in PodSpec.ResourceClaims.*

- **resources.claims.name** (string), required

Name must match the name of one entry in pod.spec.resourceClaims of the Pod where this field is used. It makes that resource available inside a container.

- **resources.limits** (map[string][Quantity](#))

Limits describes the maximum amount of compute resources allowed. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

- **resources.requests** (map[string][Quantity](#))

Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

## **lifecycle** (Lifecycle)

- Lifecycle is not allowed for ephemeral containers.

*Lifecycle describes actions that the management system should take in response to container lifecycle events. For the PostStart and PreStop lifecycle handlers, management of the container blocks until the action is complete, unless the container process fails, in which case the handler is aborted.*

- **lifecycle.postStart** ([LifecycleHandler](#))

PostStart is called immediately after a container is created. If the handler fails, the container is terminated and restarted according to its restart policy. Other management of the container blocks until the hook completes. More info: <https://kubernetes.io/docs/concepts/containers/container-lifecycle-hooks/#container-hooks>

- **lifecycle.preStop** ([LifecycleHandler](#))

PreStop is called immediately before a container is terminated due to an API request or management event such as liveness/startup probe failure, preemption, resource contention, etc. The handler is not called if the container crashes or exits. The Pod's termination grace period countdown begins before the PreStop hook is executed. Regardless of the outcome of the handler, the container will eventually terminate within the Pod's termination grace period (unless delayed by finalizers). Other management of the container blocks until the hook completes or until the termination grace period is reached. More info: <https://kubernetes.io/docs/concepts/containers/container-lifecycle-hooks/#container-hooks>

- **livenessProbe** ([Probe](#))

Probes are not allowed for ephemeral containers.

- **readinessProbe** ([Probe](#))

Probes are not allowed for ephemeral containers.

- **startupProbe** ([Probe](#))

Probes are not allowed for ephemeral containers.

## **LifecycleHandler**

LifecycleHandler defines a specific action that should be taken in a lifecycle hook. One and only one of the fields, except TCPSocket must be specified.

---

- **exec** (ExecAction)

Exec specifies the action to take.

*ExecAction describes a "run in container" action.*

- **exec.command** ([]string)

Command is the command line to execute inside the container, the working directory for the command is root ('/') in the container's filesystem. The command is simply exec'd, it is not run inside a shell, so traditional shell instructions ('|', etc) won't work. To use a shell, you need to explicitly call out to that shell. Exit status of 0 is treated as live/healthy and non-zero is unhealthy.

- **httpGet** (HTTPGetAction)

HTTPGet specifies the http request to perform.

*HTTPGetAction describes an action based on HTTP Get requests.*

- **httpGet.port** (IntOrString), required

Name or number of the port to access on the container. Number must be in the range 1 to 65535. Name must be an IANA\_SVC\_NAME.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **httpGet.host** (string)

Host name to connect to, defaults to the pod IP. You probably want to set "Host" in httpHeaders instead.

- **httpGet.httpHeaders** ([]HTTPHeader)

Custom headers to set in the request. HTTP allows repeated headers.

*HTTPHeader describes a custom header to be used in HTTP probes*

- **httpGet.httpHeaders.name** (string), required

The header field name. This will be canonicalized upon output, so case-variant names will be understood as the same header.

- **httpGet.httpHeaders.value** (string), required

The header field value

- **httpGet.path** (string)

Path to access on the HTTP server.

- **httpGet.scheme** (string)

Scheme to use for connecting to the host. Defaults to HTTP.

- **tcpSocket** (TCPSocketAction)

Deprecated. TCPSocket is NOT supported as a LifecycleHandler and kept for the backward compatibility. There are no validation of this field and lifecycle hooks will fail in runtime when tcp handler is specified.

*TCPSocketAction describes an action based on opening a socket*

- **tcpSocket.port** (IntOrString), required

Number or name of the port to access on the container. Number must be in the range 1 to 65535. Name must be an IANA\_SVC\_NAME.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **tcpSocket.host** (string)

Optional: Host name to connect to, defaults to the pod IP.

## NodeAffinity

Node affinity is a group of node affinity scheduling rules.

---

- **preferredDuringSchedulingIgnoredDuringExecution** ([]PreferredSchedulingTerm)

The scheduler will prefer to schedule pods to nodes that satisfy the affinity expressions specified by this field, but it may choose a node that violates one or more of the expressions. The node that is most preferred is the one with the greatest sum of weights, i.e. for each node that meets all of the scheduling requirements (resource request, requiredDuringScheduling affinity expressions, etc.), compute a sum by iterating through the elements of this field and adding "weight" to the sum if the node matches the corresponding matchExpressions; the node(s) with the highest sum are the most preferred.

*An empty preferred scheduling term matches all objects with implicit weight 0 (i.e. it's a no-op). A null preferred scheduling term matches no objects (i.e. is also a no-op).*

- **preferredDuringSchedulingIgnoredDuringExecution.preference** (NodeSelectorTerm), required

A node selector term, associated with the corresponding weight.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **preferredDuringSchedulingIgnoredDuringExecution.preference.matchExpressions** ([][NodeSelectorRequirement](#))

A list of node selector requirements by node's labels.

- **preferredDuringSchedulingIgnoredDuringExecution.preference.matchFields** ([][NodeSelectorRequirement](#))

A list of node selector requirements by node's fields.

- **preferredDuringSchedulingIgnoredDuringExecution.weight** (int32), required

Weight associated with matching the corresponding nodeSelectorTerm, in the range 1-100.

- **requiredDuringSchedulingIgnoredDuringExecution** (NodeSelector)

If the affinity requirements specified by this field are not met at scheduling time, the pod will not be scheduled onto the node. If the affinity requirements specified by this field cease to be met at some point during pod execution (e.g. due to an update), the system may or may not try to eventually evict the pod from its node.

*A node selector represents the union of the results of one or more label queries over a set of nodes; that is, it represents the OR of the selectors represented by the node selector terms.*

- **requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms** ([]NodeSelectorTerm), required

Required. A list of node selector terms. The terms are ORed.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms.matchExpressions** ([]NodeSelectorRequirement)

A list of node selector requirements by node's labels.

- **requiredDuringSchedulingIgnoredDuringExecution.nodeSelectorTerms.matchFields** ([]NodeSelectorRequirement)

A list of node selector requirements by node's fields.

## PodAffinity

Pod affinity is a group of inter pod affinity scheduling rules.

---

- **preferredDuringSchedulingIgnoredDuringExecution** ([]WeightedPodAffinityTerm)

The scheduler will prefer to schedule pods to nodes that satisfy the affinity expressions specified by this field, but it may choose a node that violates one or more of the expressions. The node that is most preferred is the one with the greatest sum of weights, i.e. for each node that meets all of the scheduling requirements (resource request, requiredDuringScheduling affinity expressions, etc.), compute a sum by iterating through the elements of this field and adding "weight" to the sum if the node has pods which matches the corresponding podAffinityTerm; the node(s) with the highest sum are the most preferred.

*The weights of all of the matched WeightedPodAffinityTerm fields are added per-node to find the most preferred node(s)*

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm** (PodAffinityTerm), required

Required. A pod affinity term, associated with the corresponding weight.

*Defines a set of pods (namely those matching the labelSelector relative to the given namespace(s)) that this pod should be co-located (affinity) or not co-located (anti-affinity) with, where co-located is defined as running on a node whose value of the label with key matches that of any node on which a pod of the set of pods is running*

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.topologyKey** (string), required

This pod should be co-located (affinity) or not co-located (anti-affinity) with the pods matching the labelSelector in the specified namespaces, where co-located is defined as running on a node whose value of the label with key topologyKey matches that of any node on which any of the selected pods is running. Empty topologyKey is not allowed.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.labelSelector** ([LabelSelector](#))

A label query over a set of resources, in this case pods.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.namespaces** ([LabelSelector](#))

A label query over the set of namespaces that the term applies to. The term is applied to the union of the namespaces selected by this field and the ones listed in the namespaces field. null selector and null or empty namespaces list means "this pod's namespace". An empty selector ({}) matches all namespaces.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.namespaces** ([]string)

namespaces specifies a static list of namespace names that the term applies to. The term is applied to the union of the namespaces listed in this field and the ones selected by namespaceSelector. null or empty namespaces list and null namespaceSelector means "this pod's namespace".

- **preferredDuringSchedulingIgnoredDuringExecution.weight** (int32), required

weight associated with matching the corresponding podAffinityTerm, in the range 1-100.

- **requiredDuringSchedulingIgnoredDuringExecution** ([]PodAffinityTerm)

If the affinity requirements specified by this field are not met at scheduling time, the pod will not be scheduled onto the node. If the affinity requirements specified by this field cease to be met at some point during pod execution (e.g. due to a pod label update), the system may or may not try to eventually evict the pod from its node. When there are multiple elements, the lists of nodes corresponding to each podAffinityTerm are intersected, i.e. all terms must be satisfied.

*Defines a set of pods (namely those matching the labelSelector relative to the given namespace(s)) that this pod should be co-located (affinity) or not co-located (anti-affinity)*

with, where co-located is defined as running on a node whose value of the label with key matches that of any node on which a pod of the set of pods is running

- **requiredDuringSchedulingIgnoredDuringExecution.topologyKey** (string), required

This pod should be co-located (affinity) or not co-located (anti-affinity) with the pods matching the labelSelector in the specified namespaces, where co-located is defined as running on a node whose value of the label with key topologyKey matches that of any node on which any of the selected pods is running. Empty topologyKey is not allowed.

- **requiredDuringSchedulingIgnoredDuringExecution.labelSelector** ([LabelSelector](#))

A label query over a set of resources, in this case pods.

- **requiredDuringSchedulingIgnoredDuringExecution.namespaceSelector** ([LabelSelector](#))

A label query over the set of namespaces that the term applies to. The term is applied to the union of the namespaces selected by this field and the ones listed in the namespaces field. null selector and null or empty namespaces list means "this pod's namespace". An empty selector ({} ) matches all namespaces.

- **requiredDuringSchedulingIgnoredDuringExecution.namespaces** ([]string)

namespaces specifies a static list of namespace names that the term applies to. The term is applied to the union of the namespaces listed in this field and the ones selected by namespaceSelector. null or empty namespaces list and null namespaceSelector means "this pod's namespace".

## PodAntiAffinity

Pod anti affinity is a group of inter pod anti affinity scheduling rules.

---

- **preferredDuringSchedulingIgnoredDuringExecution** ([]WeightedPodAffinityTerm)

The scheduler will prefer to schedule pods to nodes that satisfy the anti-affinity expressions specified by this field, but it may choose a node that violates one or more of the expressions. The node that is most preferred is the one with the greatest sum of weights, i.e. for each node that meets all of the scheduling requirements (resource request, requiredDuringScheduling anti-affinity expressions, etc.), compute a sum by iterating through the elements of this field and adding "weight" to the sum if the node has pods which matches the corresponding podAffinityTerm; the node(s) with the highest sum are the most preferred.

*The weights of all of the matched WeightedPodAffinityTerm fields are added per-node to find the most preferred node(s)*

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm** (PodAffinityTerm), required

Required. A pod affinity term, associated with the corresponding weight.

*Defines a set of pods (namely those matching the labelSelector relative to the given namespace(s)) that this pod should be co-located (affinity) or not co-located (anti-affinity) with, where co-located is defined as running on a node whose value of the label with key matches that of any node on which a pod of the set of pods is running*

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.topologyKey** (string), required

This pod should be co-located (affinity) or not co-located (anti-affinity) with the pods matching the labelSelector in the specified namespaces, where co-located is defined as running on a node whose value of the label with key topologyKey matches that of any node on which any of the selected pods is running. Empty topologyKey is not allowed.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.labelSelector** ([LabelSelector](#))

A label query over a set of resources, in this case pods.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.namespaces** ([LabelSelector](#))

A label query over the set of namespaces that the term applies to. The term is applied to the union of the namespaces selected by this field and the ones listed in the namespaces field. null selector and null or empty namespaces list means "this pod's namespace". An empty selector ({} ) matches all namespaces.

- **preferredDuringSchedulingIgnoredDuringExecution.podAffinityTerm.namespaces** ([]string)

namespaces specifies a static list of namespace names that the term applies to. The term is applied to the union of the namespaces listed in this field and the ones selected by namespaceSelector. null or empty namespaces list and null namespaceSelector means "this pod's namespace".

- **preferredDuringSchedulingIgnoredDuringExecution.weight** (int32), required

weight associated with matching the corresponding podAffinityTerm, in the range 1-100.

- **requiredDuringSchedulingIgnoredDuringExecution** ([]PodAffinityTerm)

If the anti-affinity requirements specified by this field are not met at scheduling time, the pod will not be scheduled onto the node. If the anti-affinity requirements specified by this field cease to be met at some point during pod execution (e.g. due to a pod label update), the system may or may not try to eventually evict the pod from its node. When there are multiple elements, the lists of nodes corresponding to each podAffinityTerm are intersected, i.e. all terms must be satisfied.

*Defines a set of pods (namely those matching the labelSelector relative to the given namespace(s)) that this pod should be co-located (affinity) or not co-located (anti-affinity)*

with, where co-located is defined as running on a node whose value of the label with key matches that of any node on which a pod of the set of pods is running

- **requiredDuringSchedulingIgnoredDuringExecution.topologyKey** (string), required

This pod should be co-located (affinity) or not co-located (anti-affinity) with the pods matching the labelSelector in the specified namespaces, where co-located is defined as running on a node whose value of the label with key topologyKey matches that of any node on which any of the selected pods is running. Empty topologyKey is not allowed.

- **requiredDuringSchedulingIgnoredDuringExecution.labelSelector** ([LabelSelector](#))

A label query over a set of resources, in this case pods.

- **requiredDuringSchedulingIgnoredDuringExecution.namespaceSelector** ([LabelSelector](#))

A label query over the set of namespaces that the term applies to. The term is applied to the union of the namespaces selected by this field and the ones listed in the namespaces field. null selector and null or empty namespaces list means "this pod's namespace". An empty selector ({} ) matches all namespaces.

- **requiredDuringSchedulingIgnoredDuringExecution.namespaces** ([]string)

namespaces specifies a static list of namespace names that the term applies to. The term is applied to the union of the namespaces listed in this field and the ones selected by namespaceSelector. null or empty namespaces list and null namespaceSelector means "this pod's namespace".

## Probe

Probe describes a health check to be performed against a container to determine whether it is alive or ready to receive traffic.

- 
- **exec** (ExecAction)

Exec specifies the action to take.

*ExecAction describes a "run in container" action.*

- **exec.command** ([]string)

Command is the command line to execute inside the container, the working directory for the command is root ('/') in the container's filesystem. The command is simply exec'd, it is not run inside a shell, so traditional shell instructions ('|', etc) won't work. To use a shell, you need to explicitly call out to that shell. Exit status of 0 is treated as live/healthy and non-zero is unhealthy.

- **httpGet** (HTTPGetAction)

HTTPGet specifies the http request to perform.

*HTTPGetAction describes an action based on HTTP Get requests.*

- **httpGet.port** (IntOrString), required

Name or number of the port to access on the container. Number must be in the range 1 to 65535. Name must be an IANA\_SVC\_NAME.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **httpGet.host** (string)

Host name to connect to, defaults to the pod IP. You probably want to set "Host" in httpHeaders instead.

- **httpGet.httpHeaders** ([]HTTPHeader)

Custom headers to set in the request. HTTP allows repeated headers.

*HTTPHeader describes a custom header to be used in HTTP probes*

- **httpGet.httpHeaders.name** (string), required

The header field name. This will be canonicalized upon output, so case-variant names will be understood as the same header.

- **httpGet.httpHeaders.value** (string), required

The header field value

- **httpGet.path** (string)

Path to access on the HTTP server.

- **httpGet.scheme** (string)

Scheme to use for connecting to the host. Defaults to HTTP.

- **tcpSocket** (TCPSocketAction)

TCPSocket specifies an action involving a TCP port.

*TCPSocketAction describes an action based on opening a socket*

- **tcpSocket.port** (IntOrString), required

Number or name of the port to access on the container. Number must be in the range 1 to 65535. Name must be an IANA\_SVC\_NAME.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

**tcpSocket.host** (string)

◦

Optional: Host name to connect to, defaults to the pod IP.

- **initialDelaySeconds** (int32)

Number of seconds after the container has started before liveness probes are initiated.

More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#container-probes>

- **terminationGracePeriodSeconds** (int64)

Optional duration in seconds the pod needs to terminate gracefully upon probe failure.

The grace period is the duration in seconds after the processes running in the pod are sent a termination signal and the time when the processes are forcibly halted with a kill signal. Set this value longer than the expected cleanup time for your process. If this value is nil, the pod's terminationGracePeriodSeconds will be used. Otherwise, this value overrides the value provided by the pod spec. Value must be non-negative integer. The value zero indicates stop immediately via the kill signal (no opportunity to shut down). This is a beta field and requires enabling ProbeTerminationGracePeriod feature gate. Minimum value is 1. spec.terminationGracePeriodSeconds is used if unset.

- **periodSeconds** (int32)

How often (in seconds) to perform the probe. Default to 10 seconds. Minimum value is 1.

- **timeoutSeconds** (int32)

Number of seconds after which the probe times out. Defaults to 1 second. Minimum value is 1. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#container-probes>

- **failureThreshold** (int32)

Minimum consecutive failures for the probe to be considered failed after having succeeded. Defaults to 3. Minimum value is 1.

- **successThreshold** (int32)

Minimum consecutive successes for the probe to be considered successful after having failed. Defaults to 1. Must be 1 for liveness and startup. Minimum value is 1.

- **grpc** (GRPCAction)

GRPC specifies an action involving a GRPC port.

\*\*

- **grpc.port** (int32), required

Port number of the gRPC service. Number must be in the range 1 to 65535.

- **grpc.service** (string)

Service is the name of the service to place in the gRPC HealthCheckRequest (see <https://github.com/grpc/grpc/blob/master/doc/health-checking.md>).

If this is not specified, the default behavior is defined by gRPC.

## PodStatus

PodStatus represents information about the status of a pod. Status may trail the actual state of a system, especially if the node that hosts the pod cannot contact the control plane.

---

- **nominatedNodeName** (string)

nominatedNodeName is set only when this pod preempts other pods on the node, but it cannot be scheduled right away as preemption victims receive their graceful termination periods. This field does not guarantee that the pod will be scheduled on this node. Scheduler may decide to place the pod elsewhere if other nodes become available sooner. Scheduler may also decide to give the resources on this node to a higher priority pod that is created after preemption. As a result, this field may be different than PodSpec.nodeName when the pod is scheduled.

- **hostIP** (string)

hostIP holds the IP address of the host to which the pod is assigned. Empty if the pod has not started yet. A pod can be assigned to a node that has a problem in kubelet which in turns mean that HostIP will not be updated even if there is a node is assigned to pod

- **hostIPs** ([]HostIP)

*Patch strategy: merge on key ip*

*Atomic: will be replaced during a merge*

hostIPs holds the IP addresses allocated to the host. If this field is specified, the first entry must match the hostIP field. This list is empty if the pod has not started yet. A pod can be assigned to a node that has a problem in kubelet which in turns means that HostIPs will not be updated even if there is a node is assigned to this pod.

*HostIP represents a single IP address allocated to the host.*

- **hostIPs.ip** (string)

IP is the IP address assigned to the host

- **startTime** (Time)

RFC 3339 date and time at which the object was acknowledged by the Kubelet. This is before the Kubelet pulled the container image(s) for the pod.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **phase** (string)

The phase of a Pod is a simple, high-level summary of where the Pod is in its lifecycle. The conditions array, the reason and message fields, and the individual container status arrays contain more detail about the pod's status. There are five possible phase values:

**Pending:** The pod has been accepted by the Kubernetes system, but one or more of the container images has not been created. This includes time before being scheduled as well as time spent downloading images over the network, which could take a while. **Running:** The pod has been bound to a node, and all of the containers have been created. At least one container is still running, or is in the process of starting or restarting. **Succeeded:** All containers in the pod have terminated in success, and will not be restarted. **Failed:** All containers in the pod have terminated, and at least one container has terminated in failure. The container either exited with non-zero status or was terminated by the system. **Unknown:** For some reason the state of the pod could not be obtained, typically due to an error in communicating with the host of the pod.

More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-phase>

- **message** (string)

A human readable message indicating details about why the pod is in this condition.

- **reason** (string)

A brief CamelCase message indicating details about why the pod is in this state. e.g. 'Evicted'

- **podIP** (string)

podIP address allocated to the pod. Routable at least within the cluster. Empty if not yet allocated.

- **podIPs** ([]PodIP)

*Patch strategy: merge on key ip*

podIPs holds the IP addresses allocated to the pod. If this field is specified, the 0th entry must match the podIP field. Pods may be allocated at most 1 value for each of IPv4 and IPv6. This list is empty if no IPs have been allocated yet.

*PodIP represents a single IP address allocated to the pod.*

- **podIPs.ip** (string)

IP is the IP address assigned to the pod

- **conditions** ([]PodCondition)

*Patch strategy: merge on key type*

Current service state of pod. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-conditions>

*PodCondition contains details for the current condition of this pod.*

- **conditions.status** (string), required

Status is the status of the condition. Can be True, False, Unknown. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-conditions>

- **conditions.type** (string), required

Type is the type of the condition. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-conditions>

- **conditions.lastProbeTime** (Time)

Last time we probed the condition.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.lastTransitionTime** (Time)

Last time the condition transitioned from one status to another.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

Human-readable message indicating details about last transition.

- **conditions.reason** (string)

Unique, one-word, CamelCase reason for the condition's last transition.

- **qosClass** (string)

The Quality of Service (QOS) classification assigned to the pod based on resource requirements See PodQOSClass type for available QOS classes More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-qos/#quality-of-service-classes>

- **initContainerStatuses** ([]ContainerStatus)

The list has one entry per init container in the manifest. The most recent successful init container will have ready = true, the most recently started container will have startTime set. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-and-container-status>

*ContainerStatus contains details for the current status of this container.*

- **containerStatuses** ([]ContainerStatus)

The list has one entry per container in the manifest. More info: <https://kubernetes.io/docs/concepts/workloads/pods/pod-lifecycle#pod-and-container-status>

*ContainerStatus contains details for the current status of this container.*

- **ephemeralContainerStatuses** ([]ContainerStatus)

Status for any ephemeral containers that have run in this pod.

*ContainerStatus contains details for the current status of this container.*

- **resourceClaimStatuses** ([]PodResourceClaimStatus)

*Patch strategies: retainKeys, merge on key name*

*Map: unique values on key name will be kept during a merge*

Status of resource claims.

*PodResourceClaimStatus is stored in the PodStatus for each PodResourceClaim which references a ResourceClaimTemplate. It stores the generated name for the corresponding ResourceClaim.*

- **resourceClaimStatuses.name** (string), required

Name uniquely identifies this resource claim inside the pod. This must match the name of an entry in pod.spec.resourceClaims, which implies that the string must be a DNS\_LABEL.

- **resourceClaimStatuses.resourceClaimName** (string)

ResourceClaimName is the name of the ResourceClaim that was generated for the Pod in the namespace of the Pod. If this is unset, then generating a ResourceClaim was not necessary. The pod.spec.resourceClaims entry can be ignored in this case.

- **resize** (string)

Status of resources resize desired for pod's containers. It is empty if no resources resize is pending. Any changes to container resources will automatically set this to "Proposed"

## PodList

PodList is a list of Pods.

- 
- **items** ([]Pod), required

List of pods. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md>

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In

CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

## Operations

---

### get read the specified Pod

#### HTTP Request

GET /api/v1/namespaces/{namespace}/pods/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the Pod
- **namespace** (*in path*): string, required  
[namespace](#)

[pretty](#)

#### Response

200 ([Pod](#)): OK

401: Unauthorized

### get read ephemeralcontainers of the specified Pod

#### HTTP Request

GET /api/v1/namespaces/{namespace}/pods/{name}/ephemeralcontainers

#### Parameters

- **name** (*in path*): string, required  
name of the Pod
- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([Pod](#)): OK

401: Unauthorized

## get read log of the specified Pod

### HTTP Request

GET /api/v1/namespaces/{namespace}/pods/{name}/log

### Parameters

- **name** (*in path*): string, required

name of the Pod

- **namespace** (*in path*): string, required

[namespace](#)

- **container** (*in query*): string

The container for which to stream logs. Defaults to only container if there is one container in the pod.

- **follow** (*in query*): boolean

Follow the log stream of the pod. Defaults to false.

- **insecureSkipTLSVerifyBackend** (*in query*): boolean

`insecureSkipTLSVerifyBackend` indicates that the apiserver should not confirm the validity of the serving certificate of the backend it is connecting to. This will make the HTTPS connection between the apiserver and the backend insecure. This means the apiserver cannot verify the log data it is receiving came from the real kubelet. If the kubelet is configured to verify the apiserver's TLS credentials, it does not mean the connection to the real kubelet is vulnerable to a man in the middle attack (e.g. an attacker could not intercept the actual log data coming from the real kubelet).

- **limitBytes** (*in query*): integer

If set, the number of bytes to read from the server before terminating the log output. This may not display a complete final line of logging, and may return slightly more or slightly less than the specified limit.

- **pretty** (*in query*): string

- [pretty](#)

- **previous** (*in query*): boolean

Return previous terminated container logs. Defaults to false.

- **sinceSeconds** (*in query*): integer

A relative time in seconds before the current time from which to show logs. If this value precedes the time a pod was started, only logs since the pod start will be returned. If this value is in the future, no logs will be returned. Only one of sinceSeconds or sinceTime may be specified.

- **tailLines** (*in query*): integer

If set, the number of lines from the end of the logs to show. If not specified, logs are shown from the creation of the container or sinceSeconds or sinceTime

- **timestamps** (*in query*): boolean

If true, add an RFC3339 or RFC3339Nano timestamp at the beginning of every line of log output. Defaults to false.

## Response

200 (string): OK

401: Unauthorized

## get read status of the specified Pod

### HTTP Request

# PodTemplate

PodTemplate describes a template for creating copies of a predefined pod.

apiVersion: v1

import "k8s.io/api/core/v1"

## PodTemplate

PodTemplate describes a template for creating copies of a predefined pod.

---

- **apiVersion:** v1
- **kind:** PodTemplate
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **template** ([PodTemplateSpec](#))

Template defines the pods that will be created from this pod template. <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## PodTemplateSpec

PodTemplateSpec describes the data a pod should have when created from a template

---

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PodSpec](#))

Specification of the desired behavior of the pod. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## PodTemplateList

PodTemplateList is a list of PodTemplates.

---

- **apiVersion:** v1
- **kind:** PodTemplateList

- **metadata** ([ListMeta](#))  
Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>
- **items** ([\[\]PodTemplate](#)), required  
List of pod templates

## Operations

# ReplicationController

ReplicationController represents the configuration of a replication controller.

apiVersion: v1

import "k8s.io/api/core/v1"

## ReplicationController

ReplicationController represents the configuration of a replication controller.

- 
- **apiVersion**: v1
  - **kind**: ReplicationController
  - **metadata** ([ObjectMeta](#))

If the Labels of a ReplicationController are empty, they are defaulted to be the same as the Pod(s) that the replication controller manages. Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([ReplicationControllerSpec](#))

Spec defines the specification of the desired behavior of the replication controller. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([ReplicationControllerStatus](#))

Status is the most recently observed status of the replication controller. This data may be out of date by some window of time. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## ReplicationControllerSpec

ReplicationControllerSpec is the specification of a replication controller.

---

- **selector** (map[string]string)

Selector is a label query over pods that should match the Replicas count. If Selector is empty, it is defaulted to the labels present on the Pod template. Label keys and values that must match in order to be controlled by this replication controller, if empty defaulted to labels on Pod template. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/#label-selectors>

- **template** ([PodTemplateSpec](#))

Template is the object that describes the pod that will be created if insufficient replicas are detected. This takes precedence over a TemplateRef. The only allowed template.spec.restartPolicy value is "Always". More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller#pod-template>

- **replicas** (int32)

Replicas is the number of desired replicas. This is a pointer to distinguish between explicit zero and unspecified. Defaults to 1. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller#what-is-a-replicationcontroller>

- **minReadySeconds** (int32)

Minimum number of seconds for which a newly created pod should be ready without any of its container crashing, for it to be considered available. Defaults to 0 (pod will be considered available as soon as it is ready)

## ReplicationControllerStatus

ReplicationControllerStatus represents the current status of a replication controller.

---

- **replicas** (int32), required

Replicas is the most recently observed number of replicas. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller#what-is-a-replicationcontroller>

- **availableReplicas** (int32)

The number of available replicas (ready for at least minReadySeconds) for this replication controller.

**readyReplicas** (int32)

- The number of ready replicas for this replication controller.

• **fullyLabeledReplicas** (int32)

The number of pods that have labels matching the labels of the pod template of the replication controller.

• **conditions** ([]ReplicationControllerCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a replication controller's current state.

*ReplicationControllerCondition describes the state of a replication controller at a certain point.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of replication controller condition.

- **conditions.lastTransitionTime** (Time)

The last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

A human readable message indicating details about the transition.

- **conditions.reason** (string)

The reason for the condition's last transition.

• **observedGeneration** (int64)

ObservedGeneration reflects the generation of the most recently observed replication controller.

## ReplicationControllerList

ReplicationControllerList is a collection of replication controllers.

---

• **apiVersion:** v1

• **kind:** ReplicationControllerList

**metadata** ([ListMeta](#))

- Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]ReplicationController](#)), required

List of replication controllers. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller>

## Operations

---

### get read the specified ReplicationController

#### HTTP Request

# ReplicaSet

ReplicaSet ensures that a specified number of pod replicas are running at any given time.

apiVersion: apps/v1

import "k8s.io/api/apps/v1"

## ReplicaSet

ReplicaSet ensures that a specified number of pod replicas are running at any given time.

- 
- **apiVersion**: apps/v1
  - **kind**: ReplicaSet
  - **metadata** ([ObjectMeta](#))

If the Labels of a ReplicaSet are empty, they are defaulted to be the same as the Pod(s) that the ReplicaSet manages. Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([ReplicaSetSpec](#))

Spec defines the specification of the desired behavior of the ReplicaSet. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([ReplicaSetStatus](#))

Status is the most recently observed status of the ReplicaSet. This data may be out of date by some window of time. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## ReplicaSetSpec

ReplicaSetSpec is the specification of a ReplicaSet.

---

- **selector** ([LabelSelector](#)), required

Selector is a label query over pods that should match the replica count. Label keys and values that must match in order to be controlled by this replica set. It must match the pod template's labels. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/#label-selectors>

- **template** ([PodTemplateSpec](#))

Template is the object that describes the pod that will be created if insufficient replicas are detected. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller#pod-template>

- **replicas** (int32)

Replicas is the number of desired replicas. This is a pointer to distinguish between explicit zero and unspecified. Defaults to 1. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller/#what-is-a-replicationcontroller>

- **minReadySeconds** (int32)

Minimum number of seconds for which a newly created pod should be ready without any of its container crashing, for it to be considered available. Defaults to 0 (pod will be considered available as soon as it is ready)

## ReplicaSetStatus

ReplicaSetStatus represents the current status of a ReplicaSet.

---

- **replicas** (int32), required

Replicas is the most recently observed number of replicas. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller/#what-is-a-replicationcontroller>

- **availableReplicas** (int32)

The number of available replicas (ready for at least minReadySeconds) for this replica set.

- **readyReplicas** (int32)

readyReplicas is the number of pods targeted by this ReplicaSet with a Ready Condition.

- **fullyLabeledReplicas** (int32)

The number of pods that have labels matching the labels of the pod template of the replicaset.

- **conditions** ([]ReplicaSetCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a replica set's current state.

*ReplicaSetCondition describes the state of a replica set at a certain point.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of replica set condition.

- **conditions.lastTransitionTime** (Time)

The last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

A human readable message indicating details about the transition.

- **conditions.reason** (string)

The reason for the condition's last transition.

- **observedGeneration** (int64)

ObservedGeneration reflects the generation of the most recently observed ReplicaSet.

## ReplicaSetList

ReplicaSetList is a collection of ReplicaSets.

---

- **apiVersion:** apps/v1

- **kind:** ReplicaSetList

**metadata** ([ListMeta](#))

- Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]ReplicaSet](#)), required

List of ReplicaSets. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller>

## Operations

---

### get read the specified ReplicaSet

#### HTTP Request

# Deployment

Deployment enables declarative updates for Pods and ReplicaSets.

apiVersion: apps/v1

import "k8s.io/api/apps/v1"

## Deployment

Deployment enables declarative updates for Pods and ReplicaSets.

- 
- **apiVersion**: apps/v1
  - **kind**: Deployment
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([DeploymentSpec](#))

Specification of the desired behavior of the Deployment.

**status** ([DeploymentStatus](#))

- Most recently observed status of the Deployment.

## DeploymentSpec

DeploymentSpec is the specification of the desired behavior of the Deployment.

---

- **selector** ([LabelSelector](#)), required

Label selector for pods. Existing ReplicaSets whose pods are selected by this will be the ones affected by this deployment. It must match the pod template's labels.

- **template** ([PodTemplateSpec](#)), required

Template describes the pods that will be created. The only allowed `template.spec.restartPolicy` value is "Always".

- **replicas** (int32)

Number of desired pods. This is a pointer to distinguish between explicit zero and not specified. Defaults to 1.

- **minReadySeconds** (int32)

Minimum number of seconds for which a newly created pod should be ready without any of its container crashing, for it to be considered available. Defaults to 0 (pod will be considered available as soon as it is ready)

- **strategy** (DeploymentStrategy)

*Patch strategy: retainKeys*

The deployment strategy to use to replace existing pods with new ones.

*DeploymentStrategy describes how to replace existing pods with new ones.*

- **strategy.type** (string)

Type of deployment. Can be "Recreate" or "RollingUpdate". Default is RollingUpdate.

- **strategy.rollingUpdate** (RollingUpdateDeployment)

Rolling update config params. Present only if DeploymentStrategyType = RollingUpdate.

*Spec to control the desired behavior of rolling update.*

- **strategy.rollingUpdate.maxSurge** (IntOrString)

The maximum number of pods that can be scheduled above the desired number of pods. Value can be an absolute number (ex: 5) or a percentage of desired pods (ex: 10%). This can not be 0 if MaxUnavailable is 0. Absolute

number is calculated from percentage by rounding up. Defaults to 25%. Example: when this is set to 30%, the new ReplicaSet can be scaled up immediately when the rolling update starts, such that the total number of old and new pods do not exceed 130% of desired pods. Once old pods have been killed, new ReplicaSet can be scaled up further, ensuring that total number of pods running at any time during the update is at most 130% of desired pods.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **strategy.rollingUpdate.maxUnavailable** (IntOrString)

The maximum number of pods that can be unavailable during the update. Value can be an absolute number (ex: 5) or a percentage of desired pods (ex: 10%). Absolute number is calculated from percentage by rounding down. This can not be 0 if MaxSurge is 0. Defaults to 25%. Example: when this is set to 30%, the old ReplicaSet can be scaled down to 70% of desired pods immediately when the rolling update starts. Once new pods are ready, old ReplicaSet can be scaled down further, followed by scaling up the new ReplicaSet, ensuring that the total number of pods available at all times during the update is at least 70% of desired pods.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **revisionHistoryLimit** (int32)

The number of old ReplicaSets to retain to allow rollback. This is a pointer to distinguish between explicit zero and not specified. Defaults to 10.

- **progressDeadlineSeconds** (int32)

The maximum time in seconds for a deployment to make progress before it is considered to be failed. The deployment controller will continue to process failed deployments and a condition with a ProgressDeadlineExceeded reason will be surfaced in the deployment status. Note that progress will not be estimated during the time a deployment is paused. Defaults to 600s.

- **paused** (boolean)

Indicates that the deployment is paused.

## DeploymentStatus

DeploymentStatus is the most recently observed status of the Deployment.

---

- **replicas** (int32)

Total number of non-terminated pods targeted by this deployment (their labels match the selector).

- **availableReplicas** (int32)

Total number of available pods (ready for at least minReadySeconds) targeted by this deployment.

- **readyReplicas** (int32)

readyReplicas is the number of pods targeted by this Deployment with a Ready Condition.

- **unavailableReplicas** (int32)

Total number of unavailable pods targeted by this deployment. This is the total number of pods that are still required for the deployment to have 100% available capacity. They may either be pods that are running but not yet available or pods that still have not been created.

- **updatedReplicas** (int32)

Total number of non-terminated pods targeted by this deployment that have the desired template spec.

- **collisionCount** (int32)

Count of hash collisions for the Deployment. The Deployment controller uses this field as a collision avoidance mechanism when it needs to create the name for the newest ReplicaSet.

- **conditions** ([]DeploymentCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a deployment's current state.

*DeploymentCondition describes the state of a deployment at a certain point.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of deployment condition.

- **conditions.lastTransitionTime** (Time)

Last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.lastUpdateTime** (Time)

The last time this condition was updated.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

A human readable message indicating details about the transition.

- **conditions.reason** (string)

The reason for the condition's last transition.

- **observedGeneration** (int64)

The generation observed by the deployment controller.

## DeploymentList

DeploymentList is a list of Deployments.

---

- **apiVersion:** apps/v1

- **kind:** DeploymentList

- **metadata** ([ListMeta](#))

Standard list metadata.

- **items** ([\[\]Deployment](#)), required

Items is the list of Deployments.

## Operations

---

# StatefulSet

StatefulSet represents a set of pods with consistent identities.

apiVersion: apps/v1

import "k8s.io/api/apps/v1"

## StatefulSet

StatefulSet represents a set of pods with consistent identities. Identities are defined as:

- Network: A single stable DNS and hostname.
- Storage: As many VolumeClaims as requested.

The StatefulSet guarantees that a given network identity will always map to the same storage identity.

- 
- **apiVersion:** apps/v1
  - **kind:** StatefulSet
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([StatefulSetSpec](#))

Spec defines the desired identities of pods in this set.

- **status** ([StatefulSetStatus](#))

Status is the current status of Pods in this StatefulSet. This data may be out of date by some window of time.

## StatefulSetSpec

A StatefulSetSpec is the specification of a StatefulSet.

- 
- **serviceName** (string), required

serviceName is the name of the service that governs this StatefulSet. This service must exist before the StatefulSet, and is responsible for the network identity of the set. Pods get DNS/hostnames that follow the pattern: pod-specific-string.serviceName.default.svc.cluster.local where "pod-specific-string" is managed by the StatefulSet controller.

- **selector** ([LabelSelector](#)), required

selector is a label query over pods that should match the replica count. It must match the pod template's labels. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/#label-selectors>

- **template** ([PodTemplateSpec](#)), required

template is the object that describes the pod that will be created if insufficient replicas are detected. Each pod stamped out by the StatefulSet will fulfill this Template, but have a unique identity from the rest of the StatefulSet. Each pod will be named with the format <statefulsetname>-<podindex>. For example, a pod in a StatefulSet named "web" with index number "3" would be named "web-3". The only allowed template.spec.restartPolicy value is "Always".

- **replicas** (int32)

replicas is the desired number of replicas of the given Template. These are replicas in the sense that they are instantiations of the same Template, but individual replicas also have a consistent identity. If unspecified, defaults to 1.

- **updateStrategy** (StatefulSetUpdateStrategy)

updateStrategy indicates the StatefulSetUpdateStrategy that will be employed to update Pods in the StatefulSet when a revision is made to Template.

*StatefulSetUpdateStrategy indicates the strategy that the StatefulSet controller will use to perform updates. It includes any additional parameters necessary to perform the update for the indicated strategy.*

- **updateStrategy.type** (string)

Type indicates the type of the StatefulSetUpdateStrategy. Default is RollingUpdate.

- **updateStrategy.rollingUpdate** (RollingUpdateStatefulSetStrategy)

RollingUpdate is used to communicate parameters when Type is RollingUpdateStatefulSetStrategyType.

*RollingUpdateStatefulSetStrategy is used to communicate parameter for RollingUpdateStatefulSetStrategyType.*

- **updateStrategy.rollingUpdate.maxUnavailable** (IntOrString)

The maximum number of pods that can be unavailable during the update. Value can be an absolute number (ex: 5) or a percentage of desired pods (ex: 10%). Absolute number is calculated from percentage by rounding up. This can not be 0. Defaults to 1. This field is alpha-level and is only honored by servers that enable the MaxUnavailableStatefulSet feature. The field applies to all pods in the range 0 to Replicas-1. That means if there is any unavailable pod in the range 0 to Replicas-1, it will be counted towards MaxUnavailable.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

▪ **updateStrategy.rollingUpdate.partition** (int32)

Partition indicates the ordinal at which the StatefulSet should be partitioned for updates. During a rolling update, all pods from ordinal Replicas-1 to Partition are updated. All pods from ordinal Partition-1 to 0 remain untouched. This is helpful in being able to do a canary based deployment. The default value is 0.

• **podManagementPolicy** (string)

podManagementPolicy controls how pods are created during initial scale up, when replacing pods on nodes, or when scaling down. The default policy is OrderedReady, where pods are created in increasing order (pod-0, then pod-1, etc) and the controller will wait until each pod is ready before continuing. When scaling down, the pods are removed in the opposite order. The alternative policy is Parallel which will create pods in parallel to match the desired scale without waiting, and on scale down will delete all pods at once.

• **revisionHistoryLimit** (int32)

revisionHistoryLimit is the maximum number of revisions that will be maintained in the StatefulSet's revision history. The revision history consists of all revisions not represented by a currently applied StatefulSetSpec version. The default value is 10.

• **volumeClaimTemplates** ([][PersistentVolumeClaim](#))

volumeClaimTemplates is a list of claims that pods are allowed to reference. The StatefulSet controller is responsible for mapping network identities to claims in a way that maintains the identity of a pod. Every claim in this list must have at least one matching (by name) volumeMount in one container in the template. A claim in this list takes precedence over any volumes in the template, with the same name.

• **minReadySeconds** (int32)

Minimum number of seconds for which a newly created pod should be ready without any of its container crashing for it to be considered available. Defaults to 0 (pod will be considered available as soon as it is ready)

• **persistentVolumeClaimRetentionPolicy**  
(StatefulSetPersistentVolumeClaimRetentionPolicy)

persistentVolumeClaimRetentionPolicy describes the lifecycle of persistent volume claims created from volumeClaimTemplates. By default, all persistent volume claims are created as needed and retained until manually deleted. This policy allows the lifecycle to be altered, for example by deleting persistent volume claims when their stateful set is deleted, or when their pod is scaled down. This requires the StatefulSetAutoDeletePVC feature gate to be enabled, which is alpha. +optional

*StatefulSetPersistentVolumeClaimRetentionPolicy describes the policy used for PVCs created from the StatefulSet VolumeClaimTemplates.*

◦ **persistentVolumeClaimRetentionPolicy.whenDeleted** (string)

WhenDeleted specifies what happens to PVCs created from StatefulSet VolumeClaimTemplates when the StatefulSet is deleted. The default policy of Retain

causes PVCs to not be affected by StatefulSet deletion. The Delete policy causes those PVCs to be deleted.

- **persistentVolumeClaimRetentionPolicy.whenScaled** (string)

WhenScaled specifies what happens to PVCs created from StatefulSet VolumeClaimTemplates when the StatefulSet is scaled down. The default policy of Retain causes PVCs to not be affected by a scaledown. The Delete policy causes the associated PVCs for any excess pods above the replica count to be deleted.

- **ordinals** (StatefulSetOrdinals)

ordinals controls the numbering of replica indices in a StatefulSet. The default ordinals behavior assigns a "0" index to the first replica and increments the index by one for each additional replica requested. Using the ordinals field requires the StatefulSetStartOrdinal feature gate to be enabled, which is beta.

*StatefulSetOrdinals describes the policy used for replica ordinal assignment in this StatefulSet.*

- **ordinals.start** (int32)

start is the number representing the first replica's index. It may be used to number replicas from an alternate index (eg: 1-indexed) over the default 0-indexed names, or to orchestrate progressive movement of replicas from one StatefulSet to another. If set, replica indices will be in the range: [.spec.ordinals.start, .spec.ordinals.start + .spec.replicas). If unset, defaults to 0. Replica indices will be in the range: [0, .spec.replicas).

## StatefulSetStatus

StatefulSetStatus represents the current state of a StatefulSet.

---

- **replicas** (int32), required

replicas is the number of Pods created by the StatefulSet controller.

- **readyReplicas** (int32)

readyReplicas is the number of pods created for this StatefulSet with a Ready Condition.

- **currentReplicas** (int32)

currentReplicas is the number of Pods created by the StatefulSet controller from the StatefulSet version indicated by currentRevision.

- **updatedReplicas** (int32)

updatedReplicas is the number of Pods created by the StatefulSet controller from the StatefulSet version indicated by updateRevision.

- **availableReplicas** (int32)

Total number of available pods (ready for at least minReadySeconds) targeted by this statefulset.

- **collisionCount** (int32)

collisionCount is the count of hash collisions for the StatefulSet. The StatefulSet controller uses this field as a collision avoidance mechanism when it needs to create the name for the newest ControllerRevision.

- **conditions** ([]StatefulSetCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a statefulset's current state.

*StatefulSetCondition describes the state of a statefulset at a certain point.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of statefulset condition.

- **conditions.lastTransitionTime** (Time)

Last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

A human readable message indicating details about the transition.

- **conditions.reason** (string)

The reason for the condition's last transition.

- **currentRevision** (string)

currentRevision, if not empty, indicates the version of the StatefulSet used to generate Pods in the sequence [0,currentReplicas).

- **updateRevision** (string)

updateRevision, if not empty, indicates the version of the StatefulSet used to generate Pods in the sequence [replicas-updatedReplicas,replicas)

- **observedGeneration** (int64)

observedGeneration is the most recent generation observed for this StatefulSet. It corresponds to the StatefulSet's generation, which is updated on mutation by the API Server.

# StatefulSetList

StatefulSetList is a collection of StatefulSets.

---

- **apiVersion:** apps/v1
- **kind:** StatefulSetList
- **metadata** ([ListMeta](#))

Standard list's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]StatefulSet](#)), required

Items is the list of stateful sets.

## Operations

---

### get read the specified StatefulSet

#### HTTP Request

# ControllerRevision

ControllerRevision implements an immutable snapshot of state data.

apiVersion: apps/v1

import "k8s.io/api/apps/v1"

# ControllerRevision

ControllerRevision implements an immutable snapshot of state data. Clients are responsible for serializing and deserializing the objects that contain their internal state. Once a ControllerRevision has been successfully created, it can not be updated. The API Server will fail validation of all requests that attempt to mutate the Data field. ControllerRevisions may, however, be deleted. Note that, due to its use by both the DaemonSet and StatefulSet controllers for update and rollback, this object is beta. However, it may be subject to name and representation changes in future releases, and clients should not depend on its stability. It is primarily for internal use by controllers.

---

- **apiVersion:** apps/v1
- **kind:** ControllerRevision
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **revision** (int64), required

Revision indicates the revision of the state represented by Data.

- **data** (RawExtension)

Data is the serialized representation of the state.

\*RawExtension is used to hold extensions in external versions.

To use this, make a field which has RawExtension as its type in your external, versioned struct, and Object in your internal struct. You also need to register your various plugin types.

// Internal package:

```
type MyAPIObject struct { runtime.TypeMeta json:",inline" MyPlugin runtime.Object
json:"myPlugin" }
```

```
type PluginA struct { AOption string json:"aOption" }
```

// External package:

```
type MyAPIObject struct { runtime.TypeMeta json:",inline" MyPlugin
runtime.RawExtension json:"myPlugin" }
```

```
type PluginA struct { AOption string json:"aOption" }
```

// On the wire, the JSON will look something like this:

```
{ "kind": "MyAPIObject", "apiVersion": "v1", "myPlugin": { "kind": "PluginA", "aOption": "foo",
}, }
```

So what happens? Decode first uses json or yaml to unmarshal the serialized data into your external MyAPIObject. That causes the raw JSON to be stored, but not unpacked. The next step is to copy (using pkg/conversion) into the internal struct. The runtime package's DefaultScheme has conversion functions installed which will unpack the JSON stored in RawExtension, turning it into the correct object type, and storing it in the Object. (TODO: In the case where the object is of an unknown type, a runtime.Unknown object will be created and stored.)\*

## ControllerRevisionList

ControllerRevisionList is a resource containing a list of ControllerRevision objects.

---

- **apiVersion:** apps/v1
- **kind:** ControllerRevisionList
- **metadata** ([ListMeta](#))

More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

## update replace the specified ControllerRevision

### HTTP Request

PUT /apis/apps/v1/namespaces/{namespace}/controllerrevisions/{name}

### Parameters

- **name** (*in path*): string, required  
name of the ControllerRevision
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [ControllerRevision](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([ControllerRevision](#)): OK

201 ([ControllerRevision](#)): Created

401: Unauthorized

## patch partially update the specified ControllerRevision

### HTTP Request

PATCH /apis/apps/v1/namespaces/{namespace}/controllerrevisions/{name}

### Parameters

- **name** (*in path*): string, required  
name of the ControllerRevision

- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [Patch](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string

# DaemonSet

DaemonSet represents the configuration of a daemon set.

apiVersion: apps/v1

import "k8s.io/api/apps/v1"

## DaemonSet

DaemonSet represents the configuration of a daemon set.

---

- **apiVersion**: apps/v1
- **kind**: DaemonSet

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([DaemonSetSpec](#))

The desired behavior of this daemon set. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([DaemonSetStatus](#))

The current status of this daemon set. This data may be out of date by some window of time. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## DaemonSetSpec

DaemonSetSpec is the specification of a daemon set.

---

- **selector** ([LabelSelector](#)), required

A label query over pods that are managed by the daemon set. Must match in order to be controlled. It must match the pod template's labels. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/#label-selectors>

- **template** ([PodTemplateSpec](#)), required

An object that describes the pod that will be created. The DaemonSet will create exactly one copy of this pod on every node that matches the template's node selector (or on every node if no node selector is specified). The only allowed template.spec.restartPolicy value is "Always". More info: <https://kubernetes.io/docs/concepts/workloads/controllers/replicationcontroller#pod-template>

- **minReadySeconds** (int32)

The minimum number of seconds for which a newly created DaemonSet pod should be ready without any of its container crashing, for it to be considered available. Defaults to 0 (pod will be considered available as soon as it is ready).

- **updateStrategy** ([DaemonSetUpdateStrategy](#))

An update strategy to replace existing DaemonSet pods with new pods.

*DaemonSetUpdateStrategy is a struct used to control the update strategy for a DaemonSet.*

- **updateStrategy.type** (string)

Type of daemon set update. Can be "RollingUpdate" or "OnDelete". Default is RollingUpdate.

- **updateStrategy.rollingUpdate** ([RollingUpdateDaemonSet](#))

Rolling update config params. Present only if type = "RollingUpdate".

*Spec to control the desired behavior of daemon set rolling update.*

- **updateStrategy.rollingUpdate.maxSurge** (IntOrString)

The maximum number of nodes with an existing available DaemonSet pod that can have an updated DaemonSet pod during during an update. Value can be an absolute number (ex: 5) or a percentage of desired pods (ex: 10%). This can not be 0 if MaxUnavailable is 0. Absolute number is calculated from percentage by rounding up to a minimum of 1. Default value is 0. Example: when this is set to 30%, at most 30% of the total number of nodes that should be running the daemon pod (i.e. status.desiredNumberScheduled) can have their a new pod created before the old pod is marked as deleted. The update starts by launching new pods on 30% of nodes. Once an updated pod is available (Ready for at least minReadySeconds) the old DaemonSet pod on that node is marked deleted. If the old pod becomes unavailable for any reason (Ready transitions to false, is evicted, or is drained) an updated pod is immediately created on that node without considering surge limits. Allowing surge implies the possibility that the resources consumed by the daemonset on any given node can double if the readiness check fails, and so resource intensive daemonsets should take into account that they may cause evictions during disruption.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **updateStrategy.rollingUpdate.maxUnavailable** (IntOrString)

The maximum number of DaemonSet pods that can be unavailable during the update. Value can be an absolute number (ex: 5) or a percentage of total number of DaemonSet pods at the start of the update (ex: 10%). Absolute number is calculated from percentage by rounding up. This cannot be 0 if MaxSurge is 0 Default value is 1. Example: when this is set to 30%, at most 30% of the total number of nodes that should be running the daemon pod (i.e. status.desiredNumberScheduled) can have their pods stopped for an update at any given time. The update starts by stopping at most 30% of those DaemonSet pods and then brings up new DaemonSet pods in their place. Once the new pods are available, it then proceeds onto other DaemonSet pods, thus ensuring that at least 70% of original number of DaemonSet pods are available at all times during the update.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **revisionHistoryLimit** (int32)

The number of old history to retain to allow rollback. This is a pointer to distinguish between explicit zero and not specified. Defaults to 10.

# DaemonSetStatus

DaemonSetStatus represents the current status of a daemon set.

---

- **numberReady** (int32), required

numberReady is the number of nodes that should be running the daemon pod and have one or more of the daemon pod running with a Ready Condition.

- **numberAvailable** (int32)

The number of nodes that should be running the daemon pod and have one or more of the daemon pod running and available (ready for at least spec.minReadySeconds)

- **numberUnavailable** (int32)

The number of nodes that should be running the daemon pod and have none of the daemon pod running and available (ready for at least spec.minReadySeconds)

- **numberMisscheduled** (int32), required

The number of nodes that are running the daemon pod, but are not supposed to run the daemon pod. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/daemonset/>

- **desiredNumberScheduled** (int32), required

The total number of nodes that should be running the daemon pod (including nodes correctly running the daemon pod). More info: <https://kubernetes.io/docs/concepts/workloads/controllers/daemonset/>

- **currentNumberScheduled** (int32), required

The number of nodes that are running at least 1 daemon pod and are supposed to run the daemon pod. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/daemonset/>

- **updatedNumberScheduled** (int32)

The total number of nodes that are running updated daemon pod

- **collisionCount** (int32)

Count of hash collisions for the DaemonSet. The DaemonSet controller uses this field as a collision avoidance mechanism when it needs to create the name for the newest ControllerRevision.

- **conditions** ([]DaemonSetCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a DaemonSet's current state.

*DaemonSetCondition describes the state of a DaemonSet at a certain point.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of DaemonSet condition.

- **conditions.lastTransitionTime** (Time)

Last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

A human readable message indicating details about the transition.

- **conditions.reason** (string)

The reason for the condition's last transition.

- **observedGeneration** (int64)

The most recent generation observed by the daemon set controller.

## DaemonSetList

DaemonSetList is a collection of daemon sets.

- 
- **apiVersion**: apps/v1

- **kind**: DaemonSetList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]DaemonSet](#)), required

A list of daemon sets.

## Operations

---

## get read the specified DaemonSet

### HTTP Request

GET /apis/apps/v1/namespaces/{namespace}/daemonsets/{name}

### Parameters

- **name** (*in path*): string, required  
name of the DaemonSet
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([DaemonSet](#)): OK

401: Unauthorized

## get read status of the specified DaemonSet

### HTTP Request

GET /apis/apps/v1/namespaces/{namespace}/daemonsets/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the DaemonSet
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([DaemonSet](#)): OK

401: Unauthorized

## list list or watch objects of kind DaemonSet

### HTTP Request

GET /apis/apps/v1/namespaces/{namespace}/daemonsets

### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)
- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string  
[continue](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)
- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)
- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean  
[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)
- **watch** (*in query*): boolean  
[watch](#)

## Response

200 ([DaemonSetList](#)): OK

401: Unauthorized

## list list or watch objects of kind DaemonSet

### HTTP Request

GET /apis/apps/v1/daemonsets

### Parameters

- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string  
[continue](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)
- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)
- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean  
[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)

- **watch** (*in query*): boolean

- [watch](#)

## Response

200 ([DaemonSetList](#)): OK

401: Unauthorized

## create create a DaemonSet

### HTTP Request

POST /apis/apps/v1/namespaces/{namespace}/daemonsets

### Parameters

- **namespace** (*in path*): string, required

- [namespace](#)

- **body**: [DaemonSet](#), required

- **dryRun** (*in query*): string

- [dryRun](#)

- **fieldManager** (*in query*): string

- [fieldManager](#)

- **fieldValidation** (*in query*): string

- [fieldValidation](#)

- **pretty** (*in query*): string

# Job

Job represents the configuration of a single job.

apiVersion: batch/v1

import "k8s.io/api/batch/v1"

# Job

Job represents the configuration of a single job.

- 
- **apiVersion**: batch/v1
  - **kind**: Job
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([JobSpec](#))

Specification of the desired behavior of a job. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([JobStatus](#))

Current status of a job. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## JobSpec

JobSpec describes how the job execution will look like.

---

## Replicas

- **template** ([PodTemplateSpec](#)), required

Describes the pod that will be created when executing a job. The only allowed `template.spec.restartPolicy` values are "Never" or "OnFailure". More info: <https://kubernetes.io/docs/concepts/workloads/controllers/jobs-run-to-completion/>

- **parallelism** (int32)

Specifies the maximum desired number of pods the job should run at any given time. The actual number of pods running in steady state will be less than this number when  $((\text{.spec.completions} - \text{.status.successful}) < \text{.spec.parallelism})$ , i.e. when the work left to do is less than max parallelism. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/jobs-run-to-completion/>

## Lifecycle

- **completions** (int32)

Specifies the desired number of successfully finished pods the job should be run with. Setting to null means that the success of any pod signals the success of all pods, and allows parallelism to have any positive value. Setting to 1 means that parallelism is limited to 1 and the success of that pod signals the success of the job. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/jobs-run-to-completion/>

- **completionMode** (string)

`completionMode` specifies how Pod completions are tracked. It can be `NonIndexed` (default) or `Indexed`.

`NonIndexed` means that the Job is considered complete when there have been `.spec.completions` successfully completed Pods. Each Pod completion is homologous to each other.

`Indexed` means that the Pods of a Job get an associated completion index from 0 to  $(\text{.spec.completions} - 1)$ , available in the annotation `batch.kubernetes.io/job-completion-index`. The Job is considered complete when there is one successfully completed Pod for each index. When value is `Indexed`, `.spec.completions` must be specified and `.spec.parallelism` must be less than or equal to  $10^5$ . In addition, The Pod name takes the form `$(job-name)-$(index)-$(random-string)`, the Pod hostname takes the form `$(job-name)-$(index)`.

More completion modes can be added in the future. If the Job controller observes a mode that it doesn't recognize, which is possible during upgrades due to version skew, the controller skips updates for the Job.

- **backoffLimit** (int32)

Specifies the number of retries before marking this job failed. Defaults to 6

- **activeDeadlineSeconds** (int64)

Specifies the duration in seconds relative to the start`Time` that the job may be continuously active before the system tries to terminate it; value must be positive integer. If a Job is suspended (at creation or through an update), this timer will effectively be stopped and reset when the Job is resumed again.

- **ttlSecondsAfterFinished** (int32)

ttlSecondsAfterFinished limits the lifetime of a Job that has finished execution (either Complete or Failed). If this field is set, ttlSecondsAfterFinished after the Job finishes, it is eligible to be automatically deleted. When the Job is being deleted, its lifecycle guarantees (e.g. finalizers) will be honored. If this field is unset, the Job won't be automatically deleted. If this field is set to zero, the Job becomes eligible to be deleted immediately after it finishes.

- **suspend** (boolean)

suspend specifies whether the Job controller should create Pods or not. If a Job is created with suspend set to true, no Pods are created by the Job controller. If a Job is suspended after creation (i.e. the flag goes from false to true), the Job controller will delete all active Pods associated with this Job. Users must design their workload to gracefully handle this. Suspending a Job will reset the Start`Time` field of the Job, effectively resetting the ActiveDeadlineSeconds timer too. Defaults to false.

## Selector

- **selector** ([LabelSelector](#))

A label query over pods that should match the pod count. Normally, the system sets this field for you. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/#label-selectors>

- **manualSelector** (boolean)

manualSelector controls generation of pod labels and pod selectors. Leave manualSelector unset unless you are certain what you are doing. When false or unset, the system pick labels unique to this job and appends those labels to the pod template. When true, the user is responsible for picking unique labels and specifying the selector. Failure to pick a unique label may cause this and other jobs to not function correctly. However, You may see manualSelector=true in jobs that were created with the old extensions/v1beta1 API. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/jobs-run-to-completion/#specifying-your-own-pod-selector>

## Beta level

- **podFailurePolicy** (PodFailurePolicy)

Specifies the policy of handling failed pods. In particular, it allows to specify the set of actions and conditions which need to be satisfied to take the associated action. If empty, the default behaviour applies - the counter of failed pods, represented by the jobs's .status.failed field, is incremented and it is checked against the backoffLimit. This field cannot be used in combination with restartPolicy=OnFailure.

This field is beta-level. It can be used when the JobPodFailurePolicy feature gate is enabled (enabled by default).

*PodFailurePolicy describes how failed pods influence the backoffLimit.*

- **podFailurePolicy.rules** ([]PodFailurePolicyRule), required

*Atomic: will be replaced during a merge*

A list of pod failure policy rules. The rules are evaluated in order. Once a rule matches a Pod failure, the remaining of the rules are ignored. When no rule matches the Pod failure, the default handling applies - the counter of pod failures is incremented and it is checked against the backoffLimit. At most 20 elements are allowed.

*PodFailurePolicyRule describes how a pod failure is handled when the requirements are met. One of onExitCodes and onPodConditions, but not both, can be used in each rule.*

- **podFailurePolicy.rules.action** (string), required

Specifies the action taken on a pod failure when the requirements are satisfied. Possible values are:

- FailJob: indicates that the pod's job is marked as Failed and all running pods are terminated.
- FailIndex: indicates that the pod's index is marked as Failed and will not be restarted. This value is alpha-level. It can be used when the JobBackoffLimitPerIndex feature gate is enabled (disabled by default).
- Ignore: indicates that the counter towards the .backoffLimit is not incremented and a replacement pod is created.
- Count: indicates that the pod is handled in the default way - the counter towards the .backoffLimit is incremented. Additional values are considered to be added in the future. Clients should react to an unknown action by skipping the rule.

- **podFailurePolicy.rules.onPodConditions** ([]PodFailurePolicyOnPodConditionsPattern), required

*Atomic: will be replaced during a merge*

Represents the requirement on the pod conditions. The requirement is represented as a list of pod condition patterns. The requirement is satisfied if at least one pattern matches an actual pod condition. At most 20 elements are allowed.

*PodFailurePolicyOnPodConditionsPattern describes a pattern for matching an actual pod condition type.*

- **podFailurePolicy.rules.onPodConditions.status** (string), required

Specifies the required Pod condition status. To match a pod condition it is required that the specified status equals the pod condition status. Defaults to True.

- **podFailurePolicy.rules.onPodConditions.type** (string), required  
Specifies the required Pod condition type. To match a pod condition it is required that specified type equals the pod condition type.
- **podFailurePolicy.rules.onExitCodes**  
(PodFailurePolicyOnExitCodesRequirement)

Represents the requirement on the container exit codes.

*PodFailurePolicyOnExitCodesRequirement describes the requirement for handling a failed pod based on its container exit codes. In particular, it lookups the .state.terminated.exitCode for each app container and init container status, represented by the .status.containerStatuses and .status.initContainerStatuses fields in the Pod status, respectively. Containers completed with success (exit code 0) are excluded from the requirement check.*

- **podFailurePolicy.rules.onExitCodes.operator** (string), required

Represents the relationship between the container exit code(s) and the specified values. Containers completed with success (exit code 0) are excluded from the requirement check. Possible values are:

- In: the requirement is satisfied if at least one container exit code (might be multiple if there are multiple containers not restricted by the 'containerName' field) is in the set of specified values.
- NotIn: the requirement is satisfied if at least one container exit code (might be multiple if there are multiple containers not restricted by the 'containerName' field) is not in the set of specified values. Additional values are considered to be added in the future. Clients should react to an unknown operator by assuming the requirement is not satisfied.

- **podFailurePolicy.rules.onExitCodes.values** ([]int32), required

*Set: unique values will be kept during a merge*

Specifies the set of values. Each returned container exit code (might be multiple in case of multiple containers) is checked against this set of values with respect to the operator. The list of values must be ordered and must not contain duplicates. Value '0' cannot be used for the In operator. At least one element is required. At most 255 elements are allowed.

- **podFailurePolicy.rules.onExitCodes.containerName** (string)

Restricts the check for exit codes to the container with the specified name. When null, the rule applies to all containers. When specified, it should match one the container or initContainer names in the pod template.

## Alpha level

- **backoffLimitPerIndex** (int32)

Specifies the limit for the number of retries within an index before marking this index as failed. When enabled the number of failures per index is kept in the pod's `batch.kubernetes.io/job-index-failure-count` annotation. It can only be set when Job's `completionMode=Indexed`, and the Pod's restart policy is `Never`. The field is immutable. This field is alpha-level. It can be used when the `JobBackoffLimitPerIndex` feature gate is enabled (disabled by default).

- **maxFailedIndexes** (int32)

Specifies the maximal number of failed indexes before marking the Job as failed, when `backoffLimitPerIndex` is set. Once the number of failed indexes exceeds this number the entire Job is marked as Failed and its execution is terminated. When left as null the job continues execution of all of its indexes and is marked with the Complete Job condition. It can only be specified when `backoffLimitPerIndex` is set. It can be null or up to completions. It is required and must be less than or equal to  $10^4$  when is completions greater than  $10^5$ . This field is alpha-level. It can be used when the `JobBackoffLimitPerIndex` feature gate is enabled (disabled by default).

- **podReplacementPolicy** (string)

`podReplacementPolicy` specifies when to create replacement Pods. Possible values are: - `TerminatingOrFailed` means that we recreate pods when they are terminating (has a `metadata.deletionTimestamp`) or failed.

- Failed means to wait until a previously created Pod is fully terminated (has phase Failed or Succeeded) before creating a replacement Pod.

When using `podFailurePolicy`, Failed is the the only allowed value. `TerminatingOrFailed` and Failed are allowed values when `podFailurePolicy` is not in use. This is an alpha field. Enable `JobPodReplacementPolicy` to be able to use this field.

## JobStatus

JobStatus represents the current state of a Job.

---

- **startTime** (Time)

Represents time when the job controller started processing a job. When a Job is created in the suspended state, this field is not set until the first time it is resumed. This field is reset every time a Job is resumed from suspension. It is represented in RFC3339 form and is in UTC.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **completionTime** (Time)

Represents time when the job was completed. It is not guaranteed to be set in happens-before order across separate operations. It is represented in RFC3339 form and is in UTC. The completion time is only set when the job finishes successfully.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

**active** (int32)

- The number of pending and running pods.

• **failed** (int32)

The number of pods which reached phase Failed.

• **succeeded** (int32)

The number of pods which reached phase Succeeded.

• **completedIndexes** (string)

completedIndexes holds the completed indexes when .spec.completionMode = "Indexed" in a text format. The indexes are represented as decimal integers separated by commas. The numbers are listed in increasing order. Three or more consecutive numbers are compressed and represented by the first and last element of the series, separated by a hyphen. For example, if the completed indexes are 1, 3, 4, 5 and 7, they are represented as "1,3-5,7".

• **conditions** ([]JobCondition)

*Patch strategy: merge on key type*

*Atomic: will be replaced during a merge*

The latest available observations of an object's current state. When a Job fails, one of the conditions will have type "Failed" and status true. When a Job is suspended, one of the conditions will have type "Suspended" and status true; when the Job is resumed, the status of this condition will become false. When a Job is completed, one of the conditions will have type "Complete" and status true. More info: <https://kubernetes.io/docs/concepts/workloads/controllers/jobs-run-to-completion/>

*JobCondition describes current state of a job.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of job condition, Complete or Failed.

- **conditions.lastProbeTime** (Time)

Last time the condition was checked.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.lastTransitionTime** (Time)

Last time the condition transit from one status to another.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

Human readable message indicating details about last transition.

- **conditions.reason** (string)

(brief) reason for the condition's last transition.

- **uncountedTerminatedPods** (UncountedTerminatedPods)

uncountedTerminatedPods holds the UIDs of Pods that have terminated but the job controller hasn't yet accounted for in the status counters.

The job controller creates pods with a finalizer. When a pod terminates (succeeded or failed), the controller does three steps to account for it in the job status:

1. Add the pod UID to the arrays in this field.
2. Remove the pod finalizer.
3. Remove the pod UID from the arrays while increasing the corresponding counter.

Old jobs might not be tracked using this field, in which case the field remains null.

*UncountedTerminatedPods holds UIDs of Pods that have terminated but haven't been accounted in Job status counters.*

- **uncountedTerminatedPods.failed** ([]string)

*Set: unique values will be kept during a merge*

failed holds UIDs of failed Pods.

- **uncountedTerminatedPods.succeeded** ([]string)

*Set: unique values will be kept during a merge*

succeeded holds UIDs of succeeded Pods.

## Beta level

- **ready** (int32)

The number of pods which have a Ready condition.

This field is beta-level. The job controller populates the field when the feature gate JobReadyPods is enabled (enabled by default).

## Alpha level

- **failedIndexes** (string)

FailedIndexes holds the failed indexes when backoffLimitPerIndex=true. The indexes are represented in the text format analogous as for the completedIndexes field, ie. they are

kept as decimal integers separated by commas. The numbers are listed in increasing order. Three or more consecutive numbers are compressed and represented by the first and last element of the series, separated by a hyphen. For example, if the failed indexes are 1, 3, 4, 5 and 7, they are represented as "1,3-5,7". This field is alpha-level. It can be used when the `JobBackoffLimitPerIndex` feature gate is enabled (disabled by default).

- **terminating** (int32)

The number of pods which are terminating (in phase Pending or Running and have a `deletionTimestamp`).

This field is alpha-level. The job controller populates the field when the feature gate `JobPodReplacementPolicy` is enabled (disabled by default).

## JobList

JobList is a collection of jobs.

---

- **apiVersion**: batch/v1

- **kind**: JobList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]Job](#)), required

items is the list of Jobs.

## Operations

---

### get read the specified Job

#### HTTP Request

GET /apis/batch/v1/namespaces/{namespace}/jobs/{name}

#### Parameters

- **name** (*in path*): string, required

name of the Job

- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([Job](#)): OK

401: Unauthorized

## get read status of the specified Job

### HTTP Request

GET /apis/batch/v1/namespaces/{namespace}/jobs/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the Job
- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([Job](#)): OK

401: Unauthorized

## list list or watch objects of kind Job

### HTTP Request

GET /apis/batch/v1/namespaces/{namespace}/jobs

### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)
- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

# CronJob

CronJob represents the configuration of a single cron job.

apiVersion: batch/v1

import "k8s.io/api/batch/v1"

## CronJob

CronJob represents the configuration of a single cron job.

---

- **apiVersion:** batch/v1
- **kind:** CronJob
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([CronJobSpec](#))

Specification of the desired behavior of a cron job, including the schedule. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([CronJobStatus](#))

Current status of a cron job. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## CronJobSpec

CronJobSpec describes how the job execution will look like and when it will actually run.

---

- **jobTemplate** ([JobTemplateSpec](#)), required

Specifies the job that will be created when executing a CronJob.

*JobTemplateSpec describes the data a Job should have when created from a template*

- **jobTemplate.metadata** ([ObjectMeta](#))

Standard object's metadata of the jobs created from this template. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **jobTemplate.spec** ([JobSpec](#))

Specification of the desired behavior of the job. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **schedule** (string), required

The schedule in Cron format, see <https://en.wikipedia.org/wiki/Cron>.

- **timeZone** (string)

The time zone name for the given schedule, see [https://en.wikipedia.org/wiki/List of tz database time zones](https://en.wikipedia.org/wiki/List_of_tz_database_time_zones). If not specified, this will default to the time zone of the kube-controller-manager process. The set of valid time zone names and the time zone offset is loaded from the system-wide time zone database by the API server during CronJob validation and the controller manager during execution. If no system-wide time zone database can be found a bundled version of the database is used instead. If the time zone name becomes invalid during the lifetime of a CronJob or due to a change in host configuration, the controller will stop creating new new Jobs and will create a system event with the reason UnknownTimeZone. More information can be found in <https://kubernetes.io/docs/concepts/workloads/controllers/cron-jobs/#time-zones>

- **concurrencyPolicy** (string)

Specifies how to treat concurrent executions of a Job. Valid values are:

- "Allow" (default): allows CronJobs to run concurrently; - "Forbid": forbids concurrent runs, skipping next run if previous run hasn't finished yet; - "Replace": cancels currently running job and replaces it with a new one

- **startingDeadlineSeconds** (int64)

Optional deadline in seconds for starting the job if it misses scheduled time for any reason. Missed jobs executions will be counted as failed ones.

- **suspend** (boolean)

This flag tells the controller to suspend subsequent executions, it does not apply to already started executions. Defaults to false.

- **successfulJobsHistoryLimit** (int32)

The number of successful finished jobs to retain. Value must be non-negative integer. Defaults to 3.

- **failedJobsHistoryLimit** (int32)

The number of failed finished jobs to retain. Value must be non-negative integer. Defaults to 1.

## CronJobStatus

CronJobStatus represents the current state of a cron job.

---

- **active** ([][ObjectReference](#))

*Atomic: will be replaced during a merge*

A list of pointers to currently running jobs.

- **lastScheduleTime** (Time)

Information when was the last time the job was successfully scheduled.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **lastSuccessfulTime** (Time)

Information when was the last time the job successfully completed.

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

## CronJobList

CronJobList is a collection of cron jobs.

---

- **apiVersion:** batch/v1

- **kind:** CronJobList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]CronJob](#)), required

items is the list of CronJobs.

## Operations

---

### get read the specified CronJob

#### HTTP Request

GET /apis/batch/v1/namespaces/{namespace}/cronjobs/{name}

#### Parameters

- **name** (*in path*): string, required

name of the CronJob

- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([CronJob](#)): OK

401: Unauthorized

## get read status of the specified CronJob

### HTTP Request

GET /apis/batch/v1/namespaces/{namespace}/cronjobs/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the CronJob
- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([CronJob](#)): OK

401: Unauthorized

# HorizontalPodAutoscaler

configuration of a horizontal pod autoscaler.

apiVersion: autoscaling/v1

import "k8s.io/api/autoscaling/v1"

## HorizontalPodAutoscaler

configuration of a horizontal pod autoscaler.

---

- **apiVersion:** autoscaling/v1
- **kind:** HorizontalPodAutoscaler
- **metadata** ([ObjectMeta](#))

Standard object metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([HorizontalPodAutoscalerSpec](#))

spec defines the behaviour of autoscaler. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>.

- **status** ([HorizontalPodAutoscalerStatus](#))

status is the current information about the autoscaler.

## HorizontalPodAutoscalerSpec

specification of a horizontal pod autoscaler.

---

- **maxReplicas** (int32), required

maxReplicas is the upper limit for the number of pods that can be set by the autoscaler; cannot be smaller than MinReplicas.

- **scaleTargetRef** (CrossVersionObjectReference), required

reference to scaled resource; horizontal pod autoscaler will learn the current resource consumption and will set the desired number of pods by using its Scale subresource.

*CrossVersionObjectReference contains enough information to let you identify the referred resource.*

- **scaleTargetRef.kind** (string), required

kind is the kind of the referent; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **scaleTargetRef.name** (string), required

name is the name of the referent; More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

**scaleTargetRef.apiVersion** (string)

- apiVersion is the API version of the referent

- **minReplicas** (int32)

minReplicas is the lower limit for the number of replicas to which the autoscaler can scale down. It defaults to 1 pod. minReplicas is allowed to be 0 if the alpha feature gate HPAScaleToZero is enabled and at least one Object or External metric is configured. Scaling is active as long as at least one metric value is available.

- **targetCPUUtilizationPercentage** (int32)

targetCPUUtilizationPercentage is the target average CPU utilization (represented as a percentage of requested CPU) over all the pods; if not specified the default autoscaling policy will be used.

## HorizontalPodAutoscalerStatus

current status of a horizontal pod autoscaler

---

- **currentReplicas** (int32), required

currentReplicas is the current number of replicas of pods managed by this autoscaler.

- **desiredReplicas** (int32), required

desiredReplicas is the desired number of replicas of pods managed by this autoscaler.

- **currentCPUUtilizationPercentage** (int32)

currentCPUUtilizationPercentage is the current average CPU utilization over all pods, represented as a percentage of requested CPU, e.g. 70 means that an average pod is using now 70% of its requested CPU.

- **lastScaleTime** (Time)

lastScaleTime is the last time the HorizontalPodAutoscaler scaled the number of pods; used by the autoscaler to control how often the number of pods is changed.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **observedGeneration** (int64)

observedGeneration is the most recent generation observed by this autoscaler.

## HorizontalPodAutoscalerList

list of horizontal pod autoscaler objects.

---

- **apiVersion**: autoscaling/v1

- **kind:** HorizontalPodAutoscalerList
- **metadata** ([ListMeta](#))  
Standard list metadata.
- **items** ([\[\]HorizontalPodAutoscaler](#)), required  
items is the list of horizontal pod autoscaler objects.

## Operations

---

### get read the specified HorizontalPodAutoscaler

#### HTTP Request

GET /apis/autoscaling/v1/namespaces/{namespace}/horizontalpodautoscalers/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the HorizontalPodAutoscaler
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([HorizontalPodAutoscaler](#)): OK

401: Unauthorized

### get read status of the specified HorizontalPodAutoscaler

#### HTTP Request

GET /apis/autoscaling/v1/namespaces/{namespace}/horizontalpodautoscalers/{name}/status

#### Parameters

- **name** (*in path*): string, required  
name of the HorizontalPodAutoscaler

- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([HorizontalPodAutoscaler](#)): OK

401: Unauthorized

## list list or watch objects of kind HorizontalPodAutoscaler

### HTTP Request

GET /apis/autoscaling/v1/namespaces/{namespace}/horizontalpodautoscalers

### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)
- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string  
[continue](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)
- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)

- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean  
[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)
- **watch** (*in query*): boolean  
[watch](#)

## Response

200 ([HorizontalPodAutoscalerList](#)): OK

401: Unauthorized

## list list or watch objects of kind HorizontalPodAutoscaler

## HTTP Request

GET /apis/autoscaling/v1/horizontalpodautoscalers

## Parameters

- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string  
[continue](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)
- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)

- **resourceVersion** (*in query*): string  
[resourceVersion](#)

# HorizontalPodAutoscaler

HorizontalPodAutoscaler is the configuration for a horizontal pod autoscaler, which automatically manages the replica count of any resource implementing the scale subresource based on the metrics specified.

apiVersion: autoscaling/v2

import "k8s.io/api/autoscaling/v2"

## HorizontalPodAutoscaler

HorizontalPodAutoscaler is the configuration for a horizontal pod autoscaler, which automatically manages the replica count of any resource implementing the scale subresource based on the metrics specified.

- 
- **apiVersion**: autoscaling/v2
  - **kind**: HorizontalPodAutoscaler
  - **metadata** ([ObjectMeta](#))

metadata is the standard object metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

**spec** ([HorizontalPodAutoscalerSpec](#))

- spec is the specification for the behaviour of the autoscaler. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>.

• **status** ([HorizontalPodAutoscalerStatus](#))

status is the current information about the autoscaler.

## HorizontalPodAutoscalerSpec

HorizontalPodAutoscalerSpec describes the desired functionality of the HorizontalPodAutoscaler.

---

• **maxReplicas** (int32), required

maxReplicas is the upper limit for the number of replicas to which the autoscaler can scale up. It cannot be less than minReplicas.

• **scaleTargetRef** (CrossVersionObjectReference), required

scaleTargetRef points to the target resource to scale, and is used to the pods for which metrics should be collected, as well as to actually change the replica count.

*CrossVersionObjectReference contains enough information to let you identify the referred resource.*

- **scaleTargetRef.kind** (string), required

kind is the kind of the referent; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **scaleTargetRef.name** (string), required

name is the name of the referent; More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **scaleTargetRef.apiVersion** (string)

apiVersion is the API version of the referent

• **minReplicas** (int32)

minReplicas is the lower limit for the number of replicas to which the autoscaler can scale down. It defaults to 1 pod. minReplicas is allowed to be 0 if the alpha feature gate HPAScaleToZero is enabled and at least one Object or External metric is configured. Scaling is active as long as at least one metric value is available.

• **behavior** (HorizontalPodAutoscalerBehavior)

behavior configures the scaling behavior of the target in both Up and Down directions (scaleUp and scaleDown fields respectively). If not set, the default HPAScalingRules for scale up and scale down are used.

*HorizontalPodAutoscalerBehavior configures the scaling behavior of the target in both Up and Down directions (scaleUp and scaleDown fields respectively).*

- **behavior.scaleDown** (HPAScalingRules)

scaleDown is scaling policy for scaling Down. If not set, the default value is to allow to scale down to minReplicas pods, with a 300 second stabilization window (i.e., the highest recommendation for the last 300sec is used).

*HPAScalingRules configures the scaling behavior for one direction. These Rules are applied after calculating DesiredReplicas from metrics for the HPA. They can limit the scaling velocity by specifying scaling policies. They can prevent flapping by specifying the stabilization window, so that the number of replicas is not set instantly, instead, the safest value from the stabilization window is chosen.*

- **behavior.scaleDown.policies** ([]HPAScalingPolicy)

*Atomic: will be replaced during a merge*

policies is a list of potential scaling policies which can be used during scaling. At least one policy must be specified, otherwise the HPAScalingRules will be discarded as invalid

*HPAScalingPolicy is a single policy which must hold true for a specified past interval.*

- **behavior.scaleDown.policies.type** (string), required

type is used to specify the scaling policy.

- **behavior.scaleDown.policies.value** (int32), required

value contains the amount of change which is permitted by the policy. It must be greater than zero

- **behavior.scaleDown.policies.periodSeconds** (int32), required

periodSeconds specifies the window of time for which the policy should hold true. PeriodSeconds must be greater than zero and less than or equal to 1800 (30 min).

- **behavior.scaleDown.selectPolicy** (string)

selectPolicy is used to specify which policy should be used. If not set, the default value Max is used.

- **behavior.scaleDown.stabilizationWindowSeconds** (int32)

stabilizationWindowSeconds is the number of seconds for which past recommendations should be considered while scaling up or scaling down. StabilizationWindowSeconds must be greater than or equal to zero and less than or equal to 3600 (one hour). If not set, use the default values: - For scale up: 0 (i.e. no stabilization is done). - For scale down: 300 (i.e. the stabilization window is 300 seconds long).

## **behavior.scaleUp** (HPAScalingRules)

- scaleUp is scaling policy for scaling Up. If not set, the default value is the higher of:

- increase no more than 4 pods per 60 seconds
- double the number of pods per 60 seconds No stabilization is used.

*HPAScalingRules configures the scaling behavior for one direction. These Rules are applied after calculating DesiredReplicas from metrics for the HPA. They can limit the scaling velocity by specifying scaling policies. They can prevent flapping by specifying the stabilization window, so that the number of replicas is not set instantly, instead, the safest value from the stabilization window is chosen.*

### ▪ **behavior.scaleUp.policies** ([]HPAScalingPolicy)

*Atomic: will be replaced during a merge*

policies is a list of potential scaling policies which can be used during scaling. At least one policy must be specified, otherwise the HPAScalingRules will be discarded as invalid

*HPAScalingPolicy is a single policy which must hold true for a specified past interval.*

#### ▪ **behavior.scaleUp.policies.type** (string), required

type is used to specify the scaling policy.

#### ▪ **behavior.scaleUp.policies.value** (int32), required

value contains the amount of change which is permitted by the policy. It must be greater than zero

#### ▪ **behavior.scaleUp.policies.periodSeconds** (int32), required

periodSeconds specifies the window of time for which the policy should hold true. PeriodSeconds must be greater than zero and less than or equal to 1800 (30 min).

### ▪ **behavior.scaleUp.selectPolicy** (string)

selectPolicy is used to specify which policy should be used. If not set, the default value Max is used.

### ▪ **behavior.scaleUp.stabilizationWindowSeconds** (int32)

stabilizationWindowSeconds is the number of seconds for which past recommendations should be considered while scaling up or scaling down. StabilizationWindowSeconds must be greater than or equal to zero and less than or equal to 3600 (one hour). If not set, use the default values: - For scale up: 0 (i.e. no stabilization is done). - For scale down: 300 (i.e. the stabilization window is 300 seconds long).

## • **metrics** ([]MetricSpec)

*Atomic: will be replaced during a merge*

metrics contains the specifications for which to use to calculate the desired replica count (the maximum replica count across all metrics will be used). The desired replica count is calculated multiplying the ratio between the target value and the current value by the current number of pods. Ergo, metrics used must decrease as the pod count is increased, and vice-versa. See the individual metric source types for more information about how each type of metric must respond. If not set, the default metric will be set to 80% average CPU utilization.

*MetricSpec specifies how to scale based on a single metric (only type and one other matching field should be set at once).*

- **metrics.type** (string), required

type is the type of metric source. It should be one of "ContainerResource", "External", "Object", "Pods" or "Resource", each mapping to a matching field in the object. Note: "ContainerResource" type is available on when the feature-gate HPAContainerMetrics is enabled

- **metrics.containerResource** (ContainerResourceMetricSource)

containerResource refers to a resource metric (such as those specified in requests and limits) known to Kubernetes describing a single container in each pod of the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source. This is an alpha feature and can be enabled by the HPAContainerMetrics feature flag.

*ContainerResourceMetricSource indicates how to scale on a resource metric known to Kubernetes, as specified in requests and limits, describing each pod in the current scale target (e.g. CPU or memory). The values will be averaged together before being compared to the target. Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source. Only one "target" type should be set.*

- **metrics.containerResource.container** (string), required

container is the name of the container in the pods of the scaling target

- **metrics.containerResource.name** (string), required

name is the name of the resource in question.

- **metrics.containerResource.target** (MetricTarget), required

target specifies the target value for the given metric

*MetricTarget defines the target value, average value, or average utilization of a specific metric*

- **metrics.containerResource.target.type** (string), required

type represents whether the metric type is Utilization, Value, or AverageValue

- **metrics.containerResource.target.averageUtilization** (int32)

averageUtilization is the target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods. Currently only valid for Resource metric source type

- **metrics.containerResource.target.averageValue** ([Quantity](#))

averageValue is the target value of the average of the metric across all relevant pods (as a quantity)

- **metrics.containerResource.target.value** ([Quantity](#))

value is the target value of the metric (as a quantity).

- **metrics.external** (ExternalMetricSource)

external refers to a global metric that is not associated with any Kubernetes object. It allows autoscaling based on information coming from components running outside of cluster (for example length of queue in cloud messaging service, or QPS from loadbalancer running outside of cluster).

*ExternalMetricSource indicates how to scale on a metric not associated with any Kubernetes object (for example length of queue in cloud messaging service, or QPS from loadbalancer running outside of cluster).*

- **metrics.external.metric** (MetricIdentifier), required

metric identifies the target metric by name and selector

*MetricIdentifier defines the name and optionally selector for a metric*

- **metrics.external.metric.name** (string), required

name is the name of the given metric

- **metrics.external.metric.selector** ([LabelSelector](#))

selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

- **metrics.external.target** (MetricTarget), required

target specifies the target value for the given metric

*MetricTarget defines the target value, average value, or average utilization of a specific metric*

- **metrics.external.target.type** (string), required

type represents whether the metric type is Utilization, Value, or AverageValue

- **metrics.external.target.averageUtilization** (int32)

averageUtilization is the target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods. Currently only valid for Resource metric source type

- **metrics.external.target.averageValue** ([Quantity](#))

averageValue is the target value of the average of the metric across all relevant pods (as a quantity)

- **metrics.external.target.value** ([Quantity](#))

value is the target value of the metric (as a quantity).

- **metrics.object** (ObjectMetricSource)

object refers to a metric describing a single kubernetes object (for example, hits-per-second on an Ingress object).

*ObjectMetricSource indicates how to scale on a metric describing a kubernetes object (for example, hits-per-second on an Ingress object).*

- **metrics.object.describedObject** (CrossVersionObjectReference), required

describedObject specifies the descriptions of a object,such as kind,name apiVersion

*CrossVersionObjectReference contains enough information to let you identify the referred resource.*

- **metrics.object.describedObject.kind** (string), required

kind is the kind of the referent; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metrics.object.describedObject.name** (string), required

name is the name of the referent; More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **metrics.object.describedObject.apiVersion** (string)

apiVersion is the API version of the referent

- **metrics.object.metric** (MetricIdentifier), required

metric identifies the target metric by name and selector

*MetricIdentifier defines the name and optionally selector for a metric*

- **metrics.object.metric.name** (string), required

name is the name of the given metric

▪ **metrics.object.metric.selector** ([LabelSelector](#))

selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

▪ **metrics.object.target** (MetricTarget), required

target specifies the target value for the given metric

*MetricTarget defines the target value, average value, or average utilization of a specific metric*

▪ **metrics.object.target.type** (string), required

type represents whether the metric type is Utilization, Value, or AverageValue

▪ **metrics.object.target.averageUtilization** (int32)

averageUtilization is the target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods. Currently only valid for Resource metric source type

▪ **metrics.object.target.averageValue** ([Quantity](#))

averageValue is the target value of the average of the metric across all relevant pods (as a quantity)

▪ **metrics.object.target.value** ([Quantity](#))

value is the target value of the metric (as a quantity).

◦ **metrics.pods** (PodsMetricSource)

pods refers to a metric describing each pod in the current scale target (for example, transactions-processed-per-second). The values will be averaged together before being compared to the target value.

*PodsMetricSource indicates how to scale on a metric describing each pod in the current scale target (for example, transactions-processed-per-second). The values will be averaged together before being compared to the target value.*

▪ **metrics.pods.metric** (MetricIdentifier), required

metric identifies the target metric by name and selector

*MetricIdentifier defines the name and optionally selector for a metric*

▪ **metrics.pods.metric.name** (string), required

name is the name of the given metric

▪ **metrics.pods.metric.selector** ([LabelSelector](#))

selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

▪ **metrics.pods.target** (MetricTarget), required

target specifies the target value for the given metric

*MetricTarget defines the target value, average value, or average utilization of a specific metric*

▪ **metrics.pods.target.type** (string), required

type represents whether the metric type is Utilization, Value, or AverageValue

▪ **metrics.pods.target.averageUtilization** (int32)

averageUtilization is the target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods. Currently only valid for Resource metric source type

▪ **metrics.pods.target.averageValue** ([Quantity](#))

averageValue is the target value of the average of the metric across all relevant pods (as a quantity)

▪ **metrics.pods.target.value** ([Quantity](#))

value is the target value of the metric (as a quantity).

◦ **metrics.resource** (ResourceMetricSource)

resource refers to a resource metric (such as those specified in requests and limits) known to Kubernetes describing each pod in the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source.

*ResourceMetricSource indicates how to scale on a resource metric known to Kubernetes, as specified in requests and limits, describing each pod in the current scale target (e.g. CPU or memory). The values will be averaged together before being compared to the target. Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source. Only one "target" type should be set.*

▪ **metrics.resource.name** (string), required

name is the name of the resource in question.

▪ **metrics.resource.target** (MetricTarget), required

target specifies the target value for the given metric

*MetricTarget defines the target value, average value, or average utilization of a specific metric*

- **metrics.resource.target.type** (string), required

type represents whether the metric type is Utilization, Value, or AverageValue

- **metrics.resource.target.averageUtilization** (int32)

averageUtilization is the target value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods. Currently only valid for Resource metric source type

- **metrics.resource.target.averageValue** ([Quantity](#))

averageValue is the target value of the average of the metric across all relevant pods (as a quantity)

- **metrics.resource.target.value** ([Quantity](#))

value is the target value of the metric (as a quantity).

## HorizontalPodAutoscalerStatus

HorizontalPodAutoscalerStatus describes the current status of a horizontal pod autoscaler.

---

- **desiredReplicas** (int32), required

desiredReplicas is the desired number of replicas of pods managed by this autoscaler, as last calculated by the autoscaler.

- **conditions** ([]HorizontalPodAutoscalerCondition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

conditions is the set of conditions required for this autoscaler to scale its target, and indicates whether or not those conditions are met.

*HorizontalPodAutoscalerCondition describes the state of a HorizontalPodAutoscaler at a certain point.*

- **conditions.status** (string), required

status is the status of the condition (True, False, Unknown)

- **conditions.type** (string), required

type describes the current condition

**conditions.lastTransitionTime** (Time)

- lastTransitionTime is the last time the condition transitioned from one status to another

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

message is a human-readable explanation containing details about the transition

- **conditions.reason** (string)

reason is the reason for the condition's last transition.

- **currentMetrics** ([]MetricStatus)

*Atomic: will be replaced during a merge*

currentMetrics is the last read state of the metrics used by this autoscaler.

*MetricStatus describes the last-read state of a single metric.*

- **currentMetrics.type** (string), required

type is the type of metric source. It will be one of "ContainerResource", "External", "Object", "Pods" or "Resource", each corresponds to a matching field in the object. Note: "ContainerResource" type is available on when the feature-gate HPAContainerMetrics is enabled

- **currentMetrics.containerResource** (ContainerResourceMetricStatus)

container resource refers to a resource metric (such as those specified in requests and limits) known to Kubernetes describing a single container in each pod in the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source.

*ContainerResourceMetricStatus indicates the current value of a resource metric known to Kubernetes, as specified in requests and limits, describing a single container in each pod in the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source.*

- **currentMetrics.containerResource.container** (string), required

container is the name of the container in the pods of the scaling target

- **currentMetrics.containerResource.current** (MetricValueStatus), required

current contains the current value for the given metric

*MetricValueStatus holds the current value for a metric*

- **currentMetrics.containerResource.current.averageUtilization** (int32)

currentAverageUtilization is the current value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

- **currentMetrics.containerResource.current.averageValue** ([Quantity](#))

averageValue is the current value of the average of the metric across all relevant pods (as a quantity)

- **currentMetrics.containerResource.current.value** ([Quantity](#))

value is the current value of the metric (as a quantity).

- **currentMetrics.containerResource.name** (string), required

name is the name of the resource in question.

- **currentMetrics.external** (ExternalMetricStatus)

external refers to a global metric that is not associated with any Kubernetes object. It allows autoscaling based on information coming from components running outside of cluster (for example length of queue in cloud messaging service, or QPS from loadbalancer running outside of cluster).

*ExternalMetricStatus indicates the current value of a global metric not associated with any Kubernetes object.*

- **currentMetrics.external.current** (MetricValueStatus), required

current contains the current value for the given metric

*MetricValueStatus holds the current value for a metric*

- **currentMetrics.external.current.averageUtilization** (int32)

currentAverageUtilization is the current value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

- **currentMetrics.external.current.averageValue** ([Quantity](#))

averageValue is the current value of the average of the metric across all relevant pods (as a quantity)

- **currentMetrics.external.current.value** ([Quantity](#))

value is the current value of the metric (as a quantity).

- **currentMetrics.external.metric** (MetricIdentifier), required

metric identifies the target metric by name and selector

*MetricIdentifier defines the name and optionally selector for a metric*

- **currentMetrics.external.metric.name** (string), required

name is the name of the given metric

- **currentMetrics.external.metric.selector** ([LabelSelector](#))

selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

- **currentMetrics.object** (ObjectMetricStatus)

object refers to a metric describing a single kubernetes object (for example, hits-per-second on an Ingress object).

*ObjectMetricStatus indicates the current value of a metric describing a kubernetes object (for example, hits-per-second on an Ingress object).*

- **currentMetrics.object.current** (MetricValueStatus), required

current contains the current value for the given metric

*MetricValueStatus holds the current value for a metric*

- **currentMetrics.object.current.averageUtilization** (int32)

currentAverageUtilization is the current value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

- **currentMetrics.object.current.averageValue** ([Quantity](#))

averageValue is the current value of the average of the metric across all relevant pods (as a quantity)

- **currentMetrics.object.current.value** ([Quantity](#))

value is the current value of the metric (as a quantity).

- **currentMetrics.object.describedObject** (CrossVersionObjectReference), required

DescribedObject specifies the descriptions of a object,such as kind,name apiVersion

*CrossVersionObjectReference contains enough information to let you identify the referred resource.*

- **currentMetrics.object.describedObject.kind** (string), required

kind is the kind of the referent; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **currentMetrics.object.describedObject.name** (string), required

name is the name of the referent; More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **currentMetrics.object.describedObject.apiVersion** (string)

apiVersion is the API version of the referent

- **currentMetrics.object.metric** (MetricIdentifier), required

metric identifies the target metric by name and selector

*MetricIdentifier defines the name and optionally selector for a metric*

- **currentMetrics.object.metric.name** (string), required

name is the name of the given metric

- **currentMetrics.object.metric.selector** ([LabelSelector](#))

selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

- **currentMetrics.pods** (PodsMetricStatus)

pods refers to a metric describing each pod in the current scale target (for example, transactions-processed-per-second). The values will be averaged together before being compared to the target value.

*PodsMetricStatus indicates the current value of a metric describing each pod in the current scale target (for example, transactions-processed-per-second).*

- **currentMetrics.pods.current** (MetricValueStatus), required

current contains the current value for the given metric

*MetricValueStatus holds the current value for a metric*

- **currentMetrics.pods.current.averageUtilization** (int32)

currentAverageUtilization is the current value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

- **currentMetrics.pods.current.averageValue** ([Quantity](#))

averageValue is the current value of the average of the metric across all relevant pods (as a quantity)

- **currentMetrics.pods.current.value** ([Quantity](#))

- value is the current value of the metric (as a quantity).

- **currentMetrics.pods.metric** (MetricIdentifier), required

- metric identifies the target metric by name and selector

- MetricIdentifier defines the name and optionally selector for a metric*

- **currentMetrics.pods.metric.name** (string), required

- name is the name of the given metric

- **currentMetrics.pods.metric.selector** ([LabelSelector](#))

- selector is the string-encoded form of a standard kubernetes label selector for the given metric When set, it is passed as an additional parameter to the metrics server for more specific metrics scoping. When unset, just the metricName will be used to gather metrics.

- **currentMetrics.resource** (ResourceMetricStatus)

- resource refers to a resource metric (such as those specified in requests and limits) known to Kubernetes describing each pod in the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source.

- ResourceMetricStatus indicates the current value of a resource metric known to Kubernetes, as specified in requests and limits, describing each pod in the current scale target (e.g. CPU or memory). Such metrics are built in to Kubernetes, and have special scaling options on top of those available to normal per-pod metrics using the "pods" source.*

- **currentMetrics.resource.current** (MetricValueStatus), required

- current contains the current value for the given metric

- MetricValueStatus holds the current value for a metric*

- **currentMetrics.resource.current.averageUtilization** (int32)

- currentAverageUtilization is the current value of the average of the resource metric across all relevant pods, represented as a percentage of the requested value of the resource for the pods.

- **currentMetrics.resource.current.averageValue** ([Quantity](#))

- averageValue is the current value of the average of the metric across all relevant pods (as a quantity)

- **currentMetrics.resource.current.value** ([Quantity](#))

- value is the current value of the metric (as a quantity).

- **currentMetrics.resource.name** (string), required  
name is the name of the resource in question.
- **currentReplicas** (int32)  
  
currentReplicas is current number of replicas of pods managed by this autoscaler, as last seen by the autoscaler.
- **lastScaleTime** (Time)  
  
lastScaleTime is the last time the HorizontalPodAutoscaler scaled the number of pods, used by the autoscaler to control how often the number of pods is changed.  
  
*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*
- **observedGeneration** (int64)  
  
observedGeneration is the most recent generation observed by this autoscaler.

## HorizontalPodAutoscalerList

HorizontalPodAutoscalerList is a list of horizontal pod autoscaler objects.

---

- **apiVersion**: autoscaling/v2
- **kind**: HorizontalPodAutoscalerList
- **metadata** ([ListMeta](#))  
  
metadata is the standard list metadata.
- **items** ([\[\]HorizontalPodAutoscaler](#)), required  
  
items is the list of horizontal pod autoscaler objects.

## Operations

---

### get read the specified HorizontalPodAutoscaler

#### HTTP Request

GET /apis/autoscaling/v2/namespaces/{namespace}/horizontalpodautoscalers/{name}

#### Parameters

- **name** (*in path*): string, required  
  
name of the HorizontalPodAutoscaler

- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([HorizontalPodAutoscaler](#)): OK

401: Unauthorized

## get read status of the specified HorizontalPodAutoscaler

### HTTP Request

GET /apis/autoscaling/v2/namespaces/{namespace}/horizontalpodautoscalers/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the HorizontalPodAutoscaler
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([HorizontalPodAutoscaler](#)): OK

401: Unauthorized

## list list or watch objects of kind HorizontalPodAutoscaler

### HTTP Request

GET /apis/autoscaling/v2/namespaces/{namespace}/horizontalpodautoscalers

### Parameters

# PriorityClass

PriorityClass defines mapping from a priority class name to the priority integer value.

apiVersion: scheduling.k8s.io/v1

import "k8s.io/api/scheduling/v1"

## PriorityClass

PriorityClass defines mapping from a priority class name to the priority integer value. The value can be any valid integer.

---

- **apiVersion:** scheduling.k8s.io/v1

- **kind:** PriorityClass

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **value** (int32), required

value represents the integer value of this priority class. This is the actual priority that pods receive when they have the name of this class in their pod spec.

- **description** (string)

description is an arbitrary string that usually provides guidelines on when this priority class should be used.

- **globalDefault** (boolean)

globalDefault specifies whether this PriorityClass should be considered as the default priority for pods that do not have any priority class. Only one PriorityClass can be marked as globalDefault. However, if more than one PriorityClasses exists with their globalDefault field set to true, the smallest value of such global default PriorityClasses will be used as the default priority.

- **preemptionPolicy** (string)

preemptionPolicy is the Policy for preempting pods with lower priority. One of Never, PreemptLowerPriority. Defaults to PreemptLowerPriority if unset.

## PriorityClassList

PriorityClassList is a collection of priority classes.

---

- **apiVersion:** scheduling.k8s.io/v1

**kind:** PriorityClassList

- 
- **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([][PriorityClass](#)), required

items is the list of PriorityClasses

## Operations

---

### get read the specified PriorityClass

# PodSchedulingContext v1alpha2

PodSchedulingContext objects hold information that is needed to schedule a Pod with ResourceClaims that use "WaitForFirstConsumer" allocation mode.

apiVersion: resource.k8s.io/v1alpha2

```
import "k8s.io/api/resource/v1alpha2"
```

## PodSchedulingContext

PodSchedulingContext objects hold information that is needed to schedule a Pod with ResourceClaims that use "WaitForFirstConsumer" allocation mode.

This is an alpha type and requires enabling the DynamicResourceAllocation feature gate.

---

- **apiVersion:** resource.k8s.io/v1alpha2

- **kind:** PodSchedulingContext

- **metadata** ([ObjectMeta](#))

Standard object metadata

- **spec** ([PodSchedulingContextSpec](#)), required

Spec describes where resources for the Pod are needed.

- **status** ([PodSchedulingContextStatus](#))

Status describes where resources for the Pod can be allocated.

## PodSchedulingContextSpec

PodSchedulingContextSpec describes where resources for the Pod are needed.

---

- **potentialNodes** ([]string)

*Set: unique values will be kept during a merge*

PotentialNodes lists nodes where the Pod might be able to run.

The size of this field is limited to 128. This is large enough for many clusters. Larger clusters may need more attempts to find a node that suits all pending resources. This may get increased in the future, but not reduced.

- **selectedNode** (string)

SelectedNode is the node for which allocation of ResourceClaims that are referenced by the Pod and that use "WaitForFirstConsumer" allocation is to be attempted.

## PodSchedulingContextStatus

PodSchedulingContextStatus describes where resources for the Pod can be allocated.

---

- **resourceClaims** ([]ResourceClaimSchedulingStatus)

*Map: unique values on key name will be kept during a merge*

ResourceClaims describes resource availability for each pod.spec.resourceClaim entry where the corresponding ResourceClaim uses "WaitForFirstConsumer" allocation mode.

*ResourceClaimSchedulingStatus contains information about one particular ResourceClaim with "WaitForFirstConsumer" allocation mode.*

- **resourceClaims.name** (string)

Name matches the pod.spec.resourceClaims[\*].Name field.

- **resourceClaims.unsuitableNodes** ([]string)

*Set: unique values will be kept during a merge*

UnsuitableNodes lists nodes that the ResourceClaim cannot be allocated for.

The size of this field is limited to 128, the same as for PodSchedulingSpec.PotentialNodes. This may get increased in the future, but not reduced.

## PodSchedulingContextList

PodSchedulingContextList is a collection of Pod scheduling objects.

- 
- **apiVersion:** resource.k8s.io/v1alpha2
  - **kind:** PodSchedulingContextList
  - **metadata** ([ListMeta](#))
    - Standard list metadata
  - **items** ([][PodSchedulingContext](#)), required

Items is the list of PodSchedulingContext objects.

## Operations

---

### get read the specified PodSchedulingContext

#### HTTP Request

GET /apis/resource.k8s.io/v1alpha2/namespaces/{namespace}/podschedulingcontexts/{name}

#### Parameters

- **name** (*in path*): string, required

name of the PodSchedulingContext

- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([PodSchedulingContext](#)): OK

401: Unauthorized

## get read status of the specified PodSchedulingContext

### HTTP Request

GET /apis/resource.k8s.io/v1alpha2/namespaces/{namespace}/podschedulingcontexts/{name}/status

### Parameters

- **name** (*in path*): string, required

name of the PodSchedulingContext

- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([PodSchedulingContext](#)): OK

401: Unauthorized

## list list or watch objects of kind PodSchedulingContext

### HTTP Request

# ResourceClaim v1alpha2

ResourceClaim describes which resources are needed by a resource consumer.

apiVersion: resource.k8s.io/v1alpha2

import "k8s.io/api/resource/v1alpha2"

## ResourceClaim

ResourceClaim describes which resources are needed by a resource consumer. Its status tracks whether the resource has been allocated and what the resulting attributes are.

This is an alpha type and requires enabling the DynamicResourceAllocation feature gate.

- 
- **apiVersion**: resource.k8s.io/v1alpha2

- **kind**: ResourceClaim

- **metadata** ([ObjectMeta](#))

Standard object metadata

- **spec** ([ResourceClaimSpec](#)), required

Spec describes the desired attributes of a resource that then needs to be allocated. It can only be set once when creating the ResourceClaim.

- **status** ([ResourceClaimStatus](#))

Status describes whether the resource is available and with which attributes.

## ResourceClaimSpec

ResourceClaimSpec defines how a resource is to be allocated.

- 
- **resourceClassName** (string), required

ResourceClassName references the driver and additional parameters via the name of a ResourceClass that was created as part of the driver deployment.

- **allocationMode** (string)

Allocation can start immediately or when a Pod wants to use the resource. "WaitForFirstConsumer" is the default.

- **parametersRef** (ResourceClaimParametersReference)

ParametersRef references a separate object with arbitrary parameters that will be used by the driver when allocating a resource for the claim.

The object must be in the same namespace as the ResourceClaim.

*ResourceClaimParametersReference contains enough information to let you locate the parameters for a ResourceClaim. The object must be in the same namespace as the ResourceClaim.*

- **parametersRef.kind** (string), required

Kind is the type of resource being referenced. This is the same value as in the parameter object's metadata, for example "ConfigMap".

- **parametersRef.name** (string), required

Name is the name of resource being referenced.

- **parametersRef.apiGroup** (string)

APIGroup is the group for the resource being referenced. It is empty for the core API. This matches the group in the APIVersion that is used when creating the resources.

## ResourceClaimStatus

ResourceClaimStatus tracks whether the resource has been allocated and what the resulting attributes are.

---

- **allocation** (AllocationResult)

Allocation is set by the resource driver once a resource or set of resources has been allocated successfully. If this is not specified, the resources have not been allocated yet.

*AllocationResult contains attributes of an allocated resource.*

- **allocation.availableOnNodes** (NodeSelector)

This field will get set by the resource driver after it has allocated the resource to inform the scheduler where it can schedule Pods using the ResourceClaim.

Setting this field is optional. If null, the resource is available everywhere.

*A node selector represents the union of the results of one or more label queries over a set of nodes; that is, it represents the OR of the selectors represented by the node selector terms.*

- **allocation.availableOnNodes.nodeSelectorTerms** ([]NodeSelectorTerm), required

Required. A list of node selector terms. The terms are ORed.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **allocation.availableOnNodes.nodeSelectorTerms.matchExpressions** ([]NodeSelectorRequirement)

A list of node selector requirements by node's labels.

- **allocation.availableOnNodes.nodeSelectorTerms.matchFields** ([]NodeSelectorRequirement)

A list of node selector requirements by node's fields.

- **allocation.resourceHandles** ([]ResourceHandle)

*Atomic: will be replaced during a merge*

ResourceHandles contain the state associated with an allocation that should be maintained throughout the lifetime of a claim. Each ResourceHandle contains data that should be passed to a specific kubelet plugin once it lands on a node. This data is returned by the driver after a successful allocation and is opaque to Kubernetes. Driver documentation may explain to users how to interpret this data if needed.

Setting this field is optional. It has a maximum size of 32 entries. If null (or empty), it is assumed this allocation will be processed by a single kubelet plugin with no ResourceHandle data attached. The name of the kubelet plugin invoked will match the DriverName set in the ResourceClaimStatus this AllocationResult is embedded in.

*ResourceHandle holds opaque resource data for processing by a specific kubelet plugin.*

- **allocation.resourceHandles.data** (string)

Data contains the opaque data associated with this ResourceHandle. It is set by the controller component of the resource driver whose name matches the DriverName set in the ResourceClaimStatus this ResourceHandle is embedded in. It is set at allocation time and is intended for processing by the kubelet plugin whose name matches the DriverName set in this ResourceHandle.

The maximum size of this field is 16KiB. This may get increased in the future, but not reduced.

- **allocation.resourceHandles.driverName** (string)

DriverName specifies the name of the resource driver whose kubelet plugin should be invoked to process this ResourceHandle's data once it lands on a node. This may differ from the DriverName set in ResourceClaimStatus this ResourceHandle is embedded in.

- **allocation.shareable** (boolean)

Shareable determines whether the resource supports more than one consumer at a time.

- **deallocationRequested** (boolean)

DeallocationRequested indicates that a ResourceClaim is to be deallocated.

The driver then must deallocate this claim and reset the field together with clearing the Allocation field.

While DeallocationRequested is set, no new consumers may be added to ReservedFor.

- **driverName** (string)

DriverName is a copy of the driver name from the ResourceClass at the time when allocation started.

- **reservedFor** ([]ResourceClaimConsumerReference)

*Map: unique values on key uid will be kept during a merge*

ReservedFor indicates which entities are currently allowed to use the claim. A Pod which references a ResourceClaim which is not reserved for that Pod will not be started.

There can be at most 32 such reservations. This may get increased in the future, but not reduced.

*ResourceClaimConsumerReference contains enough information to let you locate the consumer of a ResourceClaim. The user must be a resource in the same namespace as the ResourceClaim.*

- **reservedFor.name** (string), required

Name is the name of resource being referenced.

- **reservedFor.resource** (string), required

Resource is the type of resource being referenced, for example "pods".

- **reservedFor.uid** (string), required

UID identifies exactly one incarnation of the resource.

- **reservedFor.apiGroup** (string)

APIGroup is the group for the resource being referenced. It is empty for the core API. This matches the group in the APIVersion that is used when creating the resources.

# ResourceClaimList

ResourceClaimList is a collection of claims.

---

- **apiVersion:** resource.k8s.io/v1alpha2
- **kind:** ResourceClaimList
- **metadata** ([ListMeta](#))  
Standard list metadata
- **items** ([\[\]ResourceClaim](#)), required  
Items is the list of resource claims.

## Operations

# ResourceClaimTemplate v1alpha2

ResourceClaimTemplate is used to produce ResourceClaim objects.

```
apiVersion: resource.k8s.io/v1alpha2
```

```
import "k8s.io/api/resource/v1alpha2"
```

## ResourceClaimTemplate

ResourceClaimTemplate is used to produce ResourceClaim objects.

- 
- **apiVersion:** resource.k8s.io/v1alpha2

- **kind:** ResourceClaimTemplate

- **metadata** ([ObjectMeta](#))

Standard object metadata

- **spec** ([ResourceClaimTemplateSpec](#)), required

Describes the ResourceClaim that is to be generated.

This field is immutable. A ResourceClaim will get created by the control plane for a Pod when needed and then not get updated anymore.

## ResourceClaimTemplateSpec

ResourceClaimTemplateSpec contains the metadata and fields for a ResourceClaim.

---

- **spec** ([ResourceClaimSpec](#)), required

Spec for the ResourceClaim. The entire content is copied unchanged into the ResourceClaim that gets created from this template. The same fields as in a ResourceClaim are also valid here.

- **metadata** ([ObjectMeta](#))

ObjectMeta may contain labels and annotations that will be copied into the PVC when creating it. No other fields are allowed and will be rejected during validation.

## ResourceClaimTemplateList

ResourceClaimTemplateList is a collection of claim templates.

---

- **apiVersion:** resource.k8s.io/v1alpha2

- **kind:** ResourceClaimTemplateList

- **metadata** ([ListMeta](#))

Standard list metadata

- **items** ([\[\]ResourceClaimTemplate](#)), required

Items is the list of resource claim templates.

## Operations

---

## get read the specified ResourceClaimTemplate

### HTTP Request

GET /apis/resource.k8s.io/v1alpha2/namespaces/{namespace}/resourceclaimtemplates/{name}

### Parameters

- **name** (*in path*): string, required  
name of the ResourceClaimTemplate
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([ResourceClaimTemplate](#)): OK

401: Unauthorized

## list list or watch objects of kind ResourceClaimTemplate

### HTTP Request

# ResourceClass v1alpha2

ResourceClass is used by administrators to influence how resources are allocated.

apiVersion: resource.k8s.io/v1alpha2

import "k8s.io/api/resource/v1alpha2"

## ResourceClass

ResourceClass is used by administrators to influence how resources are allocated.

This is an alpha type and requires enabling the DynamicResourceAllocation feature gate.

- 
- **apiVersion**: resource.k8s.io/v1alpha2

- **kind**: ResourceClass

- **metadata** ([ObjectMeta](#))

Standard object metadata

- **driverName** (string), required

DriverName defines the name of the dynamic resource driver that is used for allocation of a ResourceClaim that uses this class.

Resource drivers have a unique name in forward domain order (acme.example.com).

- **parametersRef** (ResourceClassParametersReference)

ParametersRef references an arbitrary separate object that may hold parameters that will be used by the driver when allocating a resource that uses this class. A dynamic resource driver can distinguish between parameters stored here and those stored in ResourceClaimSpec.

*ResourceClassParametersReference contains enough information to let you locate the parameters for a ResourceClass.*

- **parametersRef.kind** (string), required

Kind is the type of resource being referenced. This is the same value as in the parameter object's metadata.

- **parametersRef.name** (string), required

Name is the name of resource being referenced.

- **parametersRef.apiGroup** (string)

APIGroup is the group for the resource being referenced. It is empty for the core API. This matches the group in the APIVersion that is used when creating the resources.

- **parametersRef.namespace** (string)

Namespace that contains the referenced resource. Must be empty for cluster-scoped resources and non-empty for namespaced resources.

- **suitableNodes** (NodeSelector)

Only nodes matching the selector will be considered by the scheduler when trying to find a Node that fits a Pod when that Pod uses a ResourceClaim that has not been allocated yet.

Setting this field is optional. If null, all nodes are candidates.

*A node selector represents the union of the results of one or more label queries over a set of nodes; that is, it represents the OR of the selectors represented by the node selector terms.*

- **suitableNodes.nodeSelectorTerms** ([]NodeSelectorTerm), required

Required. A list of node selector terms. The terms are ORed.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **suitableNodes.nodeSelectorTerms.matchExpressions**  
([]NodeSelectorRequirement)

A list of node selector requirements by node's labels.

- **suitableNodes.nodeSelectorTerms.matchFields**  
([]NodeSelectorRequirement)

A list of node selector requirements by node's fields.

## ResourceClassList

ResourceClassList is a collection of classes.

- 
- **apiVersion:** resource.k8s.io/v1alpha2
  - **kind:** ResourceClassList

- **metadata** ([ListMeta](#))
- **items** ([\[\]ResourceClass](#)), required  
Items is the list of resource classes.

## Operations

---

### get read the specified ResourceClass

#### HTTP Request

GET /apis/resource.k8s.io/v1alpha2/resourceclasses/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the ResourceClass
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([ResourceClass](#)): OK

401: Unauthorized

### list list or watch objects of kind ResourceClass

#### HTTP Request

# Service Resources

---

## Service

Service is a named abstraction of software service (for example, mysql) consisting of local port (for example 3306) that the proxy listens on, and the selector that determines which pods will answer requests sent through the proxy.

## Endpoints

Endpoints is a collection of endpoints that implement the actual service.

## EndpointSlice

EndpointSlice represents a subset of the endpoints that implement a service.

## Ingress

Ingress is a collection of rules that allow inbound connections to reach the endpoints defined by a backend.

## IngressClass

IngressClass represents the class of the Ingress, referenced by the Ingress Spec.

# Service

Service is a named abstraction of software service (for example, mysql) consisting of local port (for example 3306) that the proxy listens on, and the selector that determines which pods will answer requests sent through the proxy.

apiVersion: v1

import "k8s.io/api/core/v1"

# Service

Service is a named abstraction of software service (for example, mysql) consisting of local port (for example 3306) that the proxy listens on, and the selector that determines which pods will answer requests sent through the proxy.

- 
- **apiVersion:** v1
  - **kind:** Service
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([ServiceSpec](#))

Spec defines the behavior of a service. <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([ServiceStatus](#))

Most recently observed status of the service. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## ServiceSpec

ServiceSpec describes the attributes that a user creates on a service.

---

- **selector** (map[string]string)

Route service traffic to pods with label keys and values matching this selector. If empty or not present, the service is assumed to have an external process managing its endpoints, which Kubernetes will not modify. Only applies to types ClusterIP, NodePort, and LoadBalancer. Ignored if type is ExternalName. More info: <https://kubernetes.io/docs/concepts/services-networking/service/>

- **ports** ([]ServicePort)

*Patch strategy: merge on key port*

*Map: unique values on keys port, protocol will be kept during a merge*

The list of ports that are exposed by this service. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#virtual-ips-and-service-proxies>

*ServicePort contains information on service's port.*

- **ports.port** (int32), required

The port that will be exposed by this service.

- **ports.targetPort** (IntOrString)

Number or name of the port to access on the pods targeted by the service. Number must be in the range 1 to 65535. Name must be an IANA\_SVC\_NAME. If this is a string, it will be looked up as a named port in the target Pod's container ports. If this is not specified, the value of the 'port' field is used (an identity map). This field is ignored for services with clusterIP=None, and should be omitted or set equal to the 'port' field. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#defining-a-service>

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **ports.protocol** (string)

The IP protocol for this port. Supports "TCP", "UDP", and "SCTP". Default is TCP.

**ports.name** (string)

- The name of this port within the service. This must be a DNS\_LABEL. All ports within a ServiceSpec must have unique names. When considering the endpoints for a Service, this must match the 'name' field in the EndpointPort. Optional if only one ServicePort is defined on this service.

◦ **ports.nodePort** (int32)

The port on each node on which this service is exposed when type is NodePort or LoadBalancer. Usually assigned by the system. If a value is specified, in-range, and not in use it will be used, otherwise the operation will fail. If not specified, a port will be allocated if this Service requires one. If this field is specified when creating a Service which does not need it, creation will fail. This field will be wiped when updating a Service to no longer need it (e.g. changing type from NodePort to ClusterIP). More info: <https://kubernetes.io/docs/concepts/services-networking/service/#type-nodeport>

◦ **ports.appProtocol** (string)

The application protocol for this port. This is used as a hint for implementations to offer richer behavior for protocols that they understand. This field follows standard Kubernetes label syntax. Valid values are either:

- Un-prefixed protocol names - reserved for IANA standard service names (as per RFC-6335 and <https://www.iana.org/assignments/service-names>).
- Kubernetes-defined prefixed names:
  - 'kubernetes.io/h2c' - HTTP/2 over cleartext as described in <https://www.rfc-editor.org/rfc/rfc7540>
  - 'kubernetes.io/ws' - WebSocket over cleartext as described in <https://www.rfc-editor.org/rfc/rfc6455>
  - 'kubernetes.io/wss' - WebSocket over TLS as described in <https://www.rfc-editor.org/rfc/rfc6455>
- Other protocols should use implementation-defined prefixed names such as mycompany.com/my-custom-protocol.

• **type** (string)

type determines how the Service is exposed. Defaults to ClusterIP. Valid options are ExternalName, ClusterIP, NodePort, and LoadBalancer. "ClusterIP" allocates a cluster-internal IP address for load-balancing to endpoints. Endpoints are determined by the selector or if that is not specified, by manual construction of an Endpoints object or EndpointSlice objects. If clusterIP is "None", no virtual IP is allocated and the endpoints are published as a set of endpoints rather than a virtual IP. "NodePort" builds on ClusterIP and allocates a port on every node which routes to the same endpoints as the clusterIP. "LoadBalancer" builds on NodePort and creates an external load-balancer (if supported in the current cloud) which routes to the same endpoints as the clusterIP. "ExternalName" aliases this service to the specified externalName. Several other fields do not apply to ExternalName services. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#publishing-services-service-types>

- **ipFamilies** ([]string)

*Atomic: will be replaced during a merge*

IPFamilies is a list of IP families (e.g. IPv4, IPv6) assigned to this service. This field is usually assigned automatically based on cluster configuration and the ipFamilyPolicy field. If this field is specified manually, the requested family is available in the cluster, and ipFamilyPolicy allows it, it will be used; otherwise creation of the service will fail. This field is conditionally mutable: it allows for adding or removing a secondary IP family, but it does not allow changing the primary IP family of the Service. Valid values are "IPv4" and "IPv6". This field only applies to Services of types ClusterIP, NodePort, and LoadBalancer, and does apply to "headless" services. This field will be wiped when updating a Service to type ExternalName.

This field may hold a maximum of two entries (dual-stack families, in either order). These families must correspond to the values of the clusterIPs field, if specified. Both clusterIPs and ipFamilies are governed by the ipFamilyPolicy field.

- **ipFamilyPolicy** (string)

IPFamilyPolicy represents the dual-stack-ness requested or required by this Service. If there is no value provided, then this field will be set to SingleStack. Services can be "SingleStack" (a single IP family), "PreferDualStack" (two IP families on dual-stack configured clusters or a single IP family on single-stack clusters), or "RequireDualStack" (two IP families on dual-stack configured clusters, otherwise fail). The ipFamilies and clusterIPs fields depend on the value of this field. This field will be wiped when updating a service to type ExternalName.

- **clusterIP** (string)

clusterIP is the IP address of the service and is usually assigned randomly. If an address is specified manually, is in-range (as per system configuration), and is not in use, it will be allocated to the service; otherwise creation of the service will fail. This field may not be changed through updates unless the type field is also being changed to ExternalName (which requires this field to be blank) or the type field is being changed from ExternalName (in which case this field may optionally be specified, as describe above). Valid values are "None", empty string (""), or a valid IP address. Setting this to "None" makes a "headless service" (no virtual IP), which is useful when direct endpoint connections are preferred and proxying is not required. Only applies to types ClusterIP, NodePort, and LoadBalancer. If this field is specified when creating a Service of type ExternalName, creation will fail. This field will be wiped when updating a Service to type ExternalName. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#virtual-ips-and-service-proxies>

- **clusterIPs** ([]string)

*Atomic: will be replaced during a merge*

ClusterIPs is a list of IP addresses assigned to this service, and are usually assigned randomly. If an address is specified manually, is in-range (as per system configuration), and is not in use, it will be allocated to the service; otherwise creation of the service will fail. This field may not be changed through updates unless the type field is also being changed to ExternalName (which requires this field to be empty) or the type field is being changed from ExternalName (in which case this field may optionally be specified, as

describe above). Valid values are "None", empty string (""), or a valid IP address. Setting this to "None" makes a "headless service" (no virtual IP), which is useful when direct endpoint connections are preferred and proxying is not required. Only applies to types ClusterIP, NodePort, and LoadBalancer. If this field is specified when creating a Service of type ExternalName, creation will fail. This field will be wiped when updating a Service to type ExternalName. If this field is not specified, it will be initialized from the clusterIP field. If this field is specified, clients must ensure that clusterIPs[0] and clusterIP have the same value.

This field may hold a maximum of two entries (dual-stack IPs, in either order). These IPs must correspond to the values of the ipFamilies field. Both clusterIPs and ipFamilies are governed by the ipFamilyPolicy field. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#virtual-ips-and-service-proxies>

- **externalIPs** ([]string)

externalIPs is a list of IP addresses for which nodes in the cluster will also accept traffic for this service. These IPs are not managed by Kubernetes. The user is responsible for ensuring that traffic arrives at a node with this IP. A common example is external load-balancers that are not part of the Kubernetes system.

- **sessionAffinity** (string)

Supports "ClientIP" and "None". Used to maintain session affinity. Enable client IP based session affinity. Must be ClientIP or None. Defaults to None. More info: <https://kubernetes.io/docs/concepts/services-networking/service/#virtual-ips-and-service-proxies>

- **loadBalancerIP** (string)

Only applies to Service Type: LoadBalancer. This feature depends on whether the underlying cloud-provider supports specifying the loadBalancerIP when a load balancer is created. This field will be ignored if the cloud-provider does not support the feature. Deprecated: This field was under-specified and its meaning varies across implementations. Using it is non-portable and it may not support dual-stack. Users are encouraged to use implementation-specific annotations when available.

- **loadBalancerSourceRanges** ([]string)

If specified and supported by the platform, this will restrict traffic through the cloud-provider load-balancer will be restricted to the specified client IPs. This field will be ignored if the cloud-provider does not support the feature." More info: <https://kubernetes.io/docs/tasks/access-application-cluster/create-external-load-balancer/>

- **loadBalancerClass** (string)

loadBalancerClass is the class of the load balancer implementation this Service belongs to. If specified, the value of this field must be a label-style identifier, with an optional prefix, e.g. "internal-vip" or "example.com/internal-vip". Unprefixed names are reserved for end-users. This field can only be set when the Service type is 'LoadBalancer'. If not set, the default load balancer implementation is used, today this is typically done through the cloud provider integration, but should apply for any default implementation. If set, it is assumed that a load balancer implementation is watching for Services with a matching class. Any default load balancer implementation (e.g. cloud providers) should ignore

Services that set this field. This field can only be set when creating or updating a Service to type 'LoadBalancer'. Once set, it can not be changed. This field will be wiped when a service is updated to a non 'LoadBalancer' type.

- **externalName** (string)

externalName is the external reference that discovery mechanisms will return as an alias for this service (e.g. a DNS CNAME record). No proxying will be involved. Must be a lowercase RFC-1123 hostname (<https://tools.ietf.org/html/rfc1123>) and requires type to be "ExternalName".

- **externalTrafficPolicy** (string)

externalTrafficPolicy describes how nodes distribute service traffic they receive on one of the Service's "externally-facing" addresses (NodePorts, ExternalIPs, and LoadBalancer IPs). If set to "Local", the proxy will configure the service in a way that assumes that external load balancers will take care of balancing the service traffic between nodes, and so each node will deliver traffic only to the node-local endpoints of the service, without masquerading the client source IP. (Traffic mistakenly sent to a node with no endpoints will be dropped.) The default value, "Cluster", uses the standard behavior of routing to all endpoints evenly (possibly modified by topology and other features). Note that traffic sent to an External IP or LoadBalancer IP from within the cluster will always get "Cluster" semantics, but clients sending to a NodePort from within the cluster may need to take traffic policy into account when picking a node.

- **internalTrafficPolicy** (string)

InternalTrafficPolicy describes how nodes distribute service traffic they receive on the ClusterIP. If set to "Local", the proxy will assume that pods only want to talk to endpoints of the service on the same node as the pod, dropping the traffic if there are no local endpoints. The default value, "Cluster", uses the standard behavior of routing to all endpoints evenly (possibly modified by topology and other features).

- **healthCheckNodePort** (int32)

healthCheckNodePort specifies the healthcheck nodePort for the service. This only applies when type is set to LoadBalancer and externalTrafficPolicy is set to Local. If a value is specified, is in-range, and is not in use, it will be used. If not specified, a value will be automatically allocated. External systems (e.g. load-balancers) can use this port to determine if a given node holds endpoints for this service or not. If this field is specified when creating a Service which does not need it, creation will fail. This field will be wiped when updating a Service to no longer need it (e.g. changing type). This field cannot be updated once set.

- **publishNotReadyAddresses** (boolean)

publishNotReadyAddresses indicates that any agent which deals with endpoints for this Service should disregard any indications of ready/not-ready. The primary use case for setting this field is for a StatefulSet's Headless Service to propagate SRV DNS records for its Pods for the purpose of peer discovery. The Kubernetes controllers that generate Endpoints and EndpointSlice resources for Services interpret this to mean that all endpoints are considered "ready" even if the Pods themselves are not. Agents which consume only Kubernetes generated endpoints through the Endpoints or EndpointSlice resources can safely assume this behavior.

### **sessionAffinityConfig** (SessionAffinityConfig)

- sessionAffinityConfig contains the configurations of session affinity.

*SessionAffinityConfig represents the configurations of session affinity.*

- **sessionAffinityConfig.clientIP** (ClientIPConfig)

clientIP contains the configurations of Client IP based session affinity.

*ClientIPConfig represents the configurations of Client IP based session affinity.*

- **sessionAffinityConfig.clientIP.timeoutSeconds** (int32)

timeoutSeconds specifies the seconds of ClientIP type session sticky time.

The value must be >0 && <=86400(for 1 day) if ServiceAffinity == "ClientIP".

Default value is 10800(for 3 hours).

- **allocateLoadBalancerNodePorts** (boolean)

allocateLoadBalancerNodePorts defines if NodePorts will be automatically allocated for services with type LoadBalancer. Default is "true". It may be set to "false" if the cluster load-balancer does not rely on NodePorts. If the caller requests specific NodePorts (by specifying a value), those requests will be respected, regardless of this field. This field may only be set for services with type LoadBalancer and will be cleared if the type is changed to any other type.

## ServiceStatus

ServiceStatus represents the current status of a service.

---

- **conditions** ([]Condition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

Current service state

*Condition contains details for one aspect of the current state of this API Resource.*

- **conditions.lastTransitionTime** (Time), required

lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string), required

message is a human readable message indicating details about the transition. This may be an empty string.

- **conditions.reason** (string), required

reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

- **conditions.status** (string), required

status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

type of condition in CamelCase or in foo.example.com/CamelCase.

- **conditions.observedGeneration** (int64)

observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

- **loadBalancer** (LoadBalancerStatus)

LoadBalancer contains the current status of the load-balancer, if one is present.

*LoadBalancerStatus represents the status of a load-balancer.*

- **loadBalancer.ingress** ([]LoadBalancerIngress)

Ingress is a list containing ingress points for the load-balancer. Traffic intended for the service should be sent to these ingress points.

*LoadBalancerIngress represents the status of a load-balancer ingress point: traffic intended for the service should be sent to an ingress point.*

- **loadBalancer.ingress.hostname** (string)

Hostname is set for load-balancer ingress points that are DNS based (typically AWS load-balancers)

- **loadBalancer.ingress.ip** (string)

IP is set for load-balancer ingress points that are IP based (typically GCE or OpenStack load-balancers)

- **loadBalancer.ingress.ipMode** (string)

IPMode specifies how the load-balancer IP behaves, and may only be specified when the ip field is specified. Setting this to "VIP" indicates that traffic is delivered to the node with the destination set to the load-balancer's IP and port. Setting this to "Proxy" indicates that traffic is delivered to the

node or pod with the destination set to the node's IP and node port or the pod's IP and port. Service implementations may use this information to adjust traffic routing.

- **loadBalancer.ingress.ports** ([]PortStatus)

*Atomic: will be replaced during a merge*

Ports is a list of records of service ports If used, every port defined in the service should have an entry in it

\*\*

- **loadBalancer.ingress.ports.port** (int32), required

Port is the port number of the service port of which status is recorded here

- **loadBalancer.ingress.ports.protocol** (string), required

Protocol is the protocol of the service port of which status is recorded here The supported values are: "TCP", "UDP", "SCTP"

- **loadBalancer.ingress.ports.error** (string)

Error is to record the problem with the service port The format of the error shall comply with the following rules: - built-in error values shall be specified in this file and those shall use CamelCase names

- cloud provider specific error values must have names that comply with the format foo.example.com/CamelCase.

## ServiceList

ServiceList holds a list of services.

- 
- **apiVersion:** v1
  - **kind:** ServiceList
  - **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([][Service](#)), required

List of services

## Operations

---

## get read the specified Service

### HTTP Request

GET /api/v1/namespaces/{namespace}/services/{name}

### Parameters

- **name** (*in path*): string, required  
name of the Service
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([Service](#)): OK

401: Unauthorized

## get read status of the specified Service

### HTTP Request

GET /api/v1/namespaces/{namespace}/services/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the Service
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

### Response

200 ([Service](#)): OK

401: Unauthorized

## list list or watch objects of kind Service

### HTTP Request

GET /api/v1/namespaces/{namespace}/services

### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)
- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)

# Endpoints

Endpoints is a collection of endpoints that implement the actual service.

apiVersion: v1

```
import "k8s.io/api/core/v1"
```

## Endpoints

Endpoints is a collection of endpoints that implement the actual service. Example:

```
Name: "mysvc",
Subsets: [
 {
 Addresses: [{"ip": "10.10.1.1"}, {"ip": "10.10.2.2"}],
 Ports: [{"name": "a", "port": 8675}, {"name": "b", "port": 309}]
 },
 {
 Addresses: [{"ip": "10.10.3.3"}],
 Ports: [{"name": "a", "port": 93}, {"name": "b", "port": 76}]
 },
]
```

---

• **apiVersion**: v1

• **kind**: Endpoints

• **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

• **subsets** ([])EndpointSubset)

The set of all endpoints is the union of all subsets. Addresses are placed into subsets according to the IPs they share. A single address with multiple ports, some of which are

ready and some of which are not (because they come from different containers) will result in the address being displayed in different subsets for the different ports. No address will appear in both `Addresses` and `NotReadyAddresses` in the same subset. Sets of addresses and ports that comprise a service.

\*`EndpointSubset` is a group of addresses with a common set of ports. The expanded set of endpoints is the Cartesian product of `Addresses` x `Ports`. For example, given:

```
{ Addresses: [{"ip": "10.10.1.1"}, {"ip": "10.10.2.2"}], Ports: [{"name": "a", "port": 8675}, {"name": "b", "port": 309}] }
```

The resulting set of endpoints can be viewed as:

a: [ 10.10.1.1:8675, 10.10.2.2:8675 ], b: [ 10.10.1.1:309, 10.10.2.2:309 ]\*

- **subsets.addresses** ([]`EndpointAddress`)

IP addresses which offer the related ports that are marked as ready. These endpoints should be considered safe for load balancers and clients to utilize.

*EndpointAddress is a tuple that describes single IP address.*

- **subsets.addresses.ip** (string), required

The IP of this endpoint. May not be loopback (127.0.0.0/8 or ::1), link-local (169.254.0.0/16 or fe80::/10), or link-local multicast (224.0.0.0/24 or ff02::/16).

- **subsets.addresses.hostname** (string)

The Hostname of this endpoint

- **subsets.addresses.nodeName** (string)

Optional: Node hosting this endpoint. This can be used to determine endpoints local to a node.

- **subsets.addresses.targetRef** ([ObjectReference](#))

Reference to object providing the endpoint.

- **subsets.notReadyAddresses** ([]`EndpointAddress`)

IP addresses which offer the related ports but are not currently marked as ready because they have not yet finished starting, have recently failed a readiness check, or have recently failed a liveness check.

*EndpointAddress is a tuple that describes single IP address.*

- **subsets.notReadyAddresses.ip** (string), required

The IP of this endpoint. May not be loopback (127.0.0.0/8 or ::1), link-local (169.254.0.0/16 or fe80::/10), or link-local multicast (224.0.0.0/24 or ff02::/16).

- **subsets.notReadyAddresses.hostname** (string)

The Hostname of this endpoint

- **subsets.notReadyAddresses.nodeName** (string)

- Optional: Node hosting this endpoint. This can be used to determine endpoints local to a node.

- **subsets.notReadyAddresses.targetRef** ([ObjectReference](#))

- Reference to object providing the endpoint.

- **subsets.ports** ([]EndpointPort)

Port numbers available on the related IP addresses.

*EndpointPort is a tuple that describes a single port.*

- **subsets.ports.port** (int32), required

- The port number of the endpoint.

- **subsets.ports.protocol** (string)

- The IP protocol for this port. Must be UDP, TCP, or SCTP. Default is TCP.

- **subsets.ports.name** (string)

- The name of this port. This must match the 'name' field in the corresponding ServicePort. Must be a DNS\_LABEL. Optional only if one port is defined.

- **subsets.ports.appProtocol** (string)

- The application protocol for this port. This is used as a hint for implementations to offer richer behavior for protocols that they understand. This field follows standard Kubernetes label syntax. Valid values are either:

- Un-prefixed protocol names - reserved for IANA standard service names (as per RFC-6335 and <https://www.iana.org/assignments/service-names>).
- Kubernetes-defined prefixed names:
  - 'kubernetes.io/h2c' - HTTP/2 over cleartext as described in <https://www.rfc-editor.org/rfc/rfc7540>
  - 'kubernetes.io/ws' - WebSocket over cleartext as described in <https://www.rfc-editor.org/rfc/rfc6455>
  - 'kubernetes.io/wss' - WebSocket over TLS as described in <https://www.rfc-editor.org/rfc/rfc6455>
- Other protocols should use implementation-defined prefixed names such as mycompany.com/my-custom-protocol.

## EndpointsList

EndpointsList is a list of endpoints.

- 
- **apiVersion:** v1
  - **kind:** EndpointsList
  - **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]Endpoints](#)), required

List of endpoints.

## Operations

---

### get read the specified Endpoints

# EndpointSlice

EndpointSlice represents a subset of the endpoints that implement a service.

apiVersion: discovery.k8s.io/v1

import "k8s.io/api/discovery/v1"

## EndpointSlice

EndpointSlice represents a subset of the endpoints that implement a service. For a given service there may be multiple EndpointSlice objects, selected by labels, which must be joined to produce the full set of endpoints.

- 
- **apiVersion**: discovery.k8s.io/v1
  - **kind**: EndpointSlice
  - **metadata** ([ObjectMeta](#))

Standard object's metadata.

**addressType** (string), required

- addressType specifies the type of address carried by this EndpointSlice. All addresses in this slice must be the same type. This field is immutable after creation. The following address types are currently supported: \* IPv4: Represents an IPv4 Address. \* IPv6: Represents an IPv6 Address. \* FQDN: Represents a Fully Qualified Domain Name.

- **endpoints** ([]Endpoint), required

*Atomic: will be replaced during a merge*

endpoints is a list of unique endpoints in this slice. Each slice may include a maximum of 1000 endpoints.

*Endpoint represents a single logical "backend" implementing a service.*

- **endpoints.addresses** ([]string), required

*Set: unique values will be kept during a merge*

addresses of this endpoint. The contents of this field are interpreted according to the corresponding EndpointSlice addressType field. Consumers must handle different types of addresses in the context of their own capabilities. This must contain at least one address but no more than 100. These are all assumed to be fungible and clients may choose to only use the first element. Refer to: <https://issue.k8s.io/106267>

- **endpoints.conditions** (EndpointConditions)

conditions contains information about the current status of the endpoint.

*EndpointConditions represents the current condition of an endpoint.*

- **endpoints.conditions.ready** (boolean)

ready indicates that this endpoint is prepared to receive traffic, according to whatever system is managing the endpoint. A nil value indicates an unknown state. In most cases consumers should interpret this unknown state as ready. For compatibility reasons, ready should never be "true" for terminating endpoints, except when the normal readiness behavior is being explicitly overridden, for example when the associated Service has set the publishNotReadyAddresses flag.

- **endpoints.conditions.serving** (boolean)

serving is identical to ready except that it is set regardless of the terminating state of endpoints. This condition should be set to true for a ready endpoint that is terminating. If nil, consumers should defer to the ready condition.

- **endpoints.conditions.terminating** (boolean)

terminating indicates that this endpoint is terminating. A nil value indicates an unknown state. Consumers should interpret this unknown state to mean that the endpoint is not terminating.

**endpoints.deprecatedTopology** (map[string]string)

- deprecatedTopology contains topology information part of the v1beta1 API. This field is deprecated, and will be removed when the v1beta1 API is removed (no sooner than kubernetes v1.24). While this field can hold values, it is not writable through the v1 API, and any attempts to write to it will be silently ignored. Topology information can be found in the zone and nodeName fields instead.

- **endpoints.hints** (EndpointHints)

hints contains information associated with how an endpoint should be consumed.

*EndpointHints provides hints describing how an endpoint should be consumed.*

- **endpoints.hints.forZones** ([]ForZone)

*Atomic: will be replaced during a merge*

forZones indicates the zone(s) this endpoint should be consumed by to enable topology aware routing.

*ForZone provides information about which zones should consume this endpoint.*

- **endpoints.hints.forZones.name** (string), required

name represents the name of the zone.

- **endpoints.hostname** (string)

hostname of this endpoint. This field may be used by consumers of endpoints to distinguish endpoints from each other (e.g. in DNS names). Multiple endpoints which use the same hostname should be considered fungible (e.g. multiple A values in DNS). Must be lowercase and pass DNS Label (RFC 1123) validation.

- **endpoints.nodeName** (string)

nodeName represents the name of the Node hosting this endpoint. This can be used to determine endpoints local to a Node.

- **endpoints.targetRef** ([ObjectReference](#))

targetRef is a reference to a Kubernetes object that represents this endpoint.

- **endpoints.zone** (string)

zone is the name of the Zone this endpoint exists in.

- **ports** ([]EndpointPort)

*Atomic: will be replaced during a merge*

ports specifies the list of network ports exposed by each endpoint in this slice. Each port must have a unique name. When ports is empty, it indicates that there are no defined ports. When a port is defined with a nil port value, it indicates "all ports". Each slice may include a maximum of 100 ports.

*EndpointPort represents a Port used by an EndpointSlice*

- **ports.port** (int32)

port represents the port number of the endpoint. If this is not specified, ports are not restricted and must be interpreted in the context of the specific consumer.

- **ports.protocol** (string)

protocol represents the IP protocol for this port. Must be UDP, TCP, or SCTP. Default is TCP.

- **ports.name** (string)

name represents the name of this port. All ports in an EndpointSlice must have a unique name. If the EndpointSlice is derived from a Kubernetes service, this corresponds to the Service.ports[].name. Name must either be an empty string or pass DNS\_LABEL validation: \* must be no more than 63 characters long. \* must consist of lower case alphanumeric characters or '-'. \* must start and end with an alphanumeric character. Default is empty string.

- **ports.appProtocol** (string)

The application protocol for this port. This is used as a hint for implementations to offer richer behavior for protocols that they understand. This field follows standard Kubernetes label syntax. Valid values are either:

- Un-prefixed protocol names - reserved for IANA standard service names (as per RFC-6335 and <https://www.iana.org/assignments/service-names>).
- Kubernetes-defined prefixed names:
  - 'kubernetes.io/h2c' - HTTP/2 over cleartext as described in <https://www.rfc-editor.org/rfc/rfc7540>
  - 'kubernetes.io/ws' - WebSocket over cleartext as described in <https://www.rfc-editor.org/rfc/rfc6455>
  - 'kubernetes.io/wss' - WebSocket over TLS as described in <https://www.rfc-editor.org/rfc/rfc6455>
- Other protocols should use implementation-defined prefixed names such as mycompany.com/my-custom-protocol.

## EndpointSliceList

EndpointSliceList represents a list of endpoint slices

- 
- **apiVersion:** discovery.k8s.io/v1
  - **kind:** EndpointSliceList
  - **metadata** ([ListMeta](#))

Standard list metadata.

- **items** ([[EndpointSlice](#)]), required  
items is the list of endpoint slices

## Operations

---

### get read the specified EndpointSlice

#### HTTP Request

GET /apis/discovery.k8s.io/v1/namespaces/{namespace}/endpointslices/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the EndpointSlice
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([EndpointSlice](#)): OK

401: Unauthorized

### list list or watch objects of kind EndpointSlice

#### HTTP Request

GET /apis/discovery.k8s.io/v1/namespaces/{namespace}/endpointslices

#### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)
- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string

# Ingress

Ingress is a collection of rules that allow inbound connections to reach the endpoints defined by a backend.

apiVersion: networking.k8s.io/v1

import "k8s.io/api/networking/v1"

## Ingress

Ingress is a collection of rules that allow inbound connections to reach the endpoints defined by a backend. An Ingress can be configured to give services externally-reachable urls, load balance traffic, terminate SSL, offer name based virtual hosting etc.

---

• **apiVersion**: networking.k8s.io/v1

• **kind**: Ingress

• **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

• **spec** ([IngressSpec](#))

spec is the desired state of the Ingress. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

• **status** ([IngressStatus](#))

status is the current state of the Ingress. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

# IngressSpec

IngressSpec describes the Ingress the user wishes to exist.

---

- **defaultBackend** ([IngressBackend](#))

defaultBackend is the backend that should handle requests that don't match any rule. If Rules are not specified, DefaultBackend must be specified. If DefaultBackend is not set, the handling of requests that do not match any of the rules will be up to the Ingress controller.

- **ingressClassName** (string)

ingressClassName is the name of an IngressClass cluster resource. Ingress controller implementations use this field to know whether they should be serving this Ingress resource, by a transitive connection (controller -> IngressClass -> Ingress resource). Although the `kubernetes.io/ingress.class` annotation (simple constant name) was never formally defined, it was widely supported by Ingress controllers to create a direct binding between Ingress controller and Ingress resources. Newly created Ingress resources should prefer using the field. However, even though the annotation is officially deprecated, for backwards compatibility reasons, ingress controllers should still honor that annotation if present.

- **rules** ([]IngressRule)

*Atomic: will be replaced during a merge*

rules is a list of host rules used to configure the Ingress. If unspecified, or no rule matches, all traffic is sent to the default backend.

*IngressRule represents the rules mapping the paths under a specified host to the related backend services. Incoming requests are first evaluated for a host match, then routed to the backend associated with the matching IngressRuleValue.*

- **rules.host** (string)

host is the fully qualified domain name of a network host, as defined by RFC 3986. Note the following deviations from the "host" part of the URI as defined in RFC 3986: 1. IPs are not allowed. Currently an IngressRuleValue can only apply to the IP in the Spec of the parent Ingress. 2. The `:` delimiter is not respected because ports are not allowed. Currently the port of an Ingress is implicitly `:80` for http and `:443` for https. Both these may change in the future. Incoming requests are matched against the host before the IngressRuleValue. If the host is unspecified, the Ingress routes all traffic based on the specified IngressRuleValue.

host can be "precise" which is a domain name without the terminating dot of a network host (e.g. "foo.bar.com") or "wildcard", which is a domain name prefixed with a single wildcard label (e.g. ".foo.com"). The wildcard character `"` must appear by itself as the first DNS label and matches only a single label. You cannot have a wildcard label by itself (e.g. Host == "\*"). Requests will be matched against the Host field in the following way: 1. If host is precise, the request matches this rule if the http host header is equal to Host. 2. If host is a wildcard, then the request matches

this rule if the http host header is to equal to the suffix (removing the first label) of the wildcard rule.

- **rules.http** (HTTPIngressRuleValue)

*HTTPIngressRuleValue is a list of http selectors pointing to backends. In the example: http:/// -> backend where where parts of the url correspond to RFC 3986, this resource will be used to match against everything after the last '/' and before the first '?' or '#'.*

- **rules.http.paths** ([]HTTPIngressPath), required

*Atomic: will be replaced during a merge*

paths is a collection of paths that map requests to backends.

*HTTPIngressPath associates a path with a backend. Incoming urls matching the path are forwarded to the backend.*

- **rules.http.paths.backend** ([IngressBackend](#)), required

backend defines the referenced service endpoint to which the traffic will be forwarded to.

- **rules.http.paths.pathType** (string), required

pathType determines the interpretation of the path matching.

PathType can be one of the following values: \* Exact: Matches the URL path exactly. \* Prefix: Matches based on a URL path prefix split by '/'. Matching is done on a path element by element basis. A path element refers is the list of labels in the path split by the '/' separator. A request is a match for path p if every p is an element-wise prefix of p of the request path. Note that if the last element of the path is a substring of the last element in request path, it is not a match (e.g. /foo/bar matches /foo/bar/baz, but does not match /foo/barbaz).

- ImplementationSpecific: Interpretation of the Path matching is up to the IngressClass. Implementations can treat this as a separate PathType or treat it identically to Prefix or Exact path types. Implementations are required to support all path types.

- **rules.http.paths.path** (string)

path is matched against the path of an incoming request. Currently it can contain characters disallowed from the conventional "path" part of a URL as defined by RFC 3986. Paths must begin with a '/' and must be present when using PathType with value "Exact" or "Prefix".

- **tls** ([]IngressTLS)

*Atomic: will be replaced during a merge*

tls represents the TLS configuration. Currently the Ingress only supports a single TLS port, 443. If multiple members of this list specify different hosts, they will be multiplexed on the same port according to the hostname specified through the SNI TLS extension, if the ingress controller fulfilling the ingress supports SNI.

*IngressTLS describes the transport layer security associated with an ingress.*

- **tls.hosts** ([]string)

*Atomic: will be replaced during a merge*

hosts is a list of hosts included in the TLS certificate. The values in this list must match the name/s used in the tlsSecret. Defaults to the wildcard host setting for the loadbalancer controller fulfilling this Ingress, if left unspecified.

- **tls.secretName** (string)

secretName is the name of the secret used to terminate TLS traffic on port 443. Field is left optional to allow TLS routing based on SNI hostname alone. If the SNI host in a listener conflicts with the "Host" header field used by an IngressRule, the SNI host is used for termination and value of the "Host" header is used for routing.

## IngressBackend

IngressBackend describes all endpoints for a given service and port.

---

- **resource** ([TypedLocalObjectReference](#))

resource is an ObjectRef to another Kubernetes resource in the namespace of the Ingress object. If resource is specified, a service.Name and service.Port must not be specified. This is a mutually exclusive setting with "Service".

- **service** (IngressServiceBackend)

service references a service as a backend. This is a mutually exclusive setting with "Resource".

*IngressServiceBackend references a Kubernetes Service as a Backend.*

- **service.name** (string), required

name is the referenced service. The service must exist in the same namespace as the Ingress object.

- **service.port** (ServiceBackendPort)

port of the referenced service. A port name or port number is required for a IngressServiceBackend.

*ServiceBackendPort is the service port being referenced.*

- **service.port.name** (string)

name is the name of the port on the Service. This is a mutually exclusive setting with "Number".

- **service.port.number** (int32)

number is the numerical port number (e.g. 80) on the Service. This is a mutually exclusive setting with "Name".

## IngressStatus

IngressStatus describe the current state of the Ingress.

---

- **loadBalancer** (IngressLoadBalancerStatus)

loadBalancer contains the current status of the load-balancer.

*IngressLoadBalancerStatus represents the status of a load-balancer.*

- **loadBalancer.ingress** ([]IngressLoadBalancerIngress)

ingress is a list containing ingress points for the load-balancer.

*IngressLoadBalancerIngress represents the status of a load-balancer ingress point.*

- **loadBalancer.ingress.hostname** (string)

hostname is set for load-balancer ingress points that are DNS based.

- **loadBalancer.ingress.ip** (string)

ip is set for load-balancer ingress points that are IP based.

- **loadBalancer.ingress.ports** ([]IngressPortStatus)

*Atomic: will be replaced during a merge*

ports provides information about the ports exposed by this LoadBalancer.

*IngressPortStatus represents the error condition of a service port*

- **loadBalancer.ingress.ports.port** (int32), required

port is the port number of the ingress port.

- **loadBalancer.ingress.ports.protocol** (string), required

protocol is the protocol of the ingress port. The supported values are: "TCP", "UDP", "SCTP"

- **loadBalancer.ingress.ports.error** (string)

error is to record the problem with the service port The format of the error shall comply with the following rules: - built-in error values shall be specified in this file and those shall use CamelCase names

- cloud provider specific error values must have names that comply with the format foo.example.com/CamelCase.

# IngressList

IngressList is a collection of Ingress.

---

- **items** ([\[\]Ingress](#)), required

items is the list of Ingress.

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metadata** ([ListMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

## Operations

---

### get read the specified Ingress

#### HTTP Request

GET /apis/networking.k8s.io/v1/namespaces/{namespace}/ingresses/{name}

# IngressClass

IngressClass represents the class of the Ingress, referenced by the Ingress Spec.

apiVersion: networking.k8s.io/v1

import "k8s.io/api/networking/v1"

## IngressClass

IngressClass represents the class of the Ingress, referenced by the Ingress Spec. The `ingressclass.kubernetes.io/is-default-class` annotation can be used to indicate that an IngressClass should be considered default. When a single IngressClass resource has this annotation set to true, new Ingress resources without a class specified will be assigned this default class.

- 
- **apiVersion:** networking.k8s.io/v1

- **kind:** IngressClass

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([IngressClassSpec](#))

spec is the desired state of the IngressClass. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## IngressClassSpec

IngressClassSpec provides information about the class of an Ingress.

- 
- **controller** (string)

controller refers to the name of the controller that should handle this class. This allows for different "flavors" that are controlled by the same controller. For example, you may have different parameters for the same implementing controller. This should be specified as a domain-prefixed path no more than 250 characters in length, e.g. "acme.io/ingress-controller". This field is immutable.

- **parameters** ([IngressClassParametersReference](#))

parameters is a link to a custom resource containing additional configuration for the controller. This is optional if the controller does not require extra parameters.

*IngressClassParametersReference identifies an API object. This can be used to specify a cluster or namespace-scoped resource.*

- **parameters.kind** (string), required

kind is the type of resource being referenced.

- **parameters.name** (string), required

name is the name of resource being referenced.

- **parameters.apiGroup** (string)

apiGroup is the group for the resource being referenced. If APIGroup is not specified, the specified Kind must be in the core API group. For any other third-party types, APIGroup is required.

- **parameters.namespace** (string)

namespace is the namespace of the resource being referenced. This field is required when scope is set to "Namespace" and must be unset when scope is set to "Cluster".

- **parameters.scope** (string)

scope represents if this refers to a cluster or namespace scoped resource. This may be set to "Cluster" (default) or "Namespace".

## IngressClassList

IngressClassList is a collection of IngressClasses.

---

- **apiVersion:** networking.k8s.io/v1

- **kind:** IngressClassList

- **metadata** ([ListMeta](#))

Standard list metadata.

- **items** ([\[\]IngressClass](#)), required

items is the list of IngressClasses.

## Operations

---

### get read the specified IngressClass

#### HTTP Request

GET /apis/networking.k8s.io/v1/ingressclasses/{name}

#### Parameters

- **name** (*in path*): string, required

name of the IngressClass

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([IngressClass](#)): OK

401: Unauthorized

## list list or watch objects of kind IngressClass

## HTTP Request

GET /apis/networking.k8s.io/v1/ingressclasses

## Parameters

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

[fieldSelector](#)

- **labelSelector** (*in query*): string

# Config and Storage Resources

---

## [ConfigMap](#)

ConfigMap holds configuration data for pods to consume.

## [Secret](#)

Secret holds secret data of a certain type.

## [Volume](#)

Volume represents a named volume in a pod that may be accessed by any container in the pod.

## [PersistentVolumeClaim](#)

PersistentVolumeClaim is a user's request for and claim to a persistent volume.

## [PersistentVolume](#)

PersistentVolume (PV) is a storage resource provisioned by an administrator.

## [StorageClass](#)

StorageClass describes the parameters for a class of storage for which PersistentVolumes can be dynamically provisioned.

## [VolumeAttachment](#)

VolumeAttachment captures the intent to attach or detach the specified volume to/from the specified node.

## [CSIDriver](#)

CSIDriver captures information about a Container Storage Interface (CSI) volume driver deployed on the cluster.

## [CSINode](#)

CSINode holds information about all CSI drivers installed on a node.

## [CSIStorageCapacity](#)

CSIStorageCapacity stores the result of one CSI GetCapacity call.

# ConfigMap

ConfigMap holds configuration data for pods to consume.

```
apiVersion: v1
```

```
import "k8s.io/api/core/v1"
```

# ConfigMap

ConfigMap holds configuration data for pods to consume.

---

- **apiVersion:** v1
- **kind:** ConfigMap
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **binaryData** (map[string][]byte)

BinaryData contains the binary data. Each key must consist of alphanumeric characters, '-', '\_' or '.'. BinaryData can contain byte sequences that are not in the UTF-8 range. The keys stored in BinaryData must not overlap with the ones in the Data field, this is enforced during validation process. Using this field will require 1.10+ apiserver and kubelet.

- **data** (map[string]string)

Data contains the configuration data. Each key must consist of alphanumeric characters, '-', '\_' or '.'. Values with non-UTF-8 byte sequences must use the BinaryData field. The keys stored in Data must not overlap with the keys in the BinaryData field, this is enforced during validation process.

- **immutable** (boolean)

Immutable, if set to true, ensures that data stored in the ConfigMap cannot be updated (only object metadata can be modified). If not set to true, the field can be modified at any time. Defaulted to nil.

## ConfigMapList

ConfigMapList is a resource containing a list of ConfigMap objects.

---

- **apiVersion:** v1
- **kind:** ConfigMapList
- **metadata** ([ListMeta](#))

More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]ConfigMap](#)), required

Items is the list of ConfigMaps.

## Operations

---

### get read the specified ConfigMap

#### HTTP Request

GET /api/v1/namespaces/{namespace}/configmaps/{name}

#### Parameters

- **name** (*in path*): string, required

# Secret

Secret holds secret data of a certain type.

```
apiVersion: v1
```

```
import "k8s.io/api/core/v1"
```

# Secret

Secret holds secret data of a certain type. The total bytes of the values in the Data field must be less than MaxSecretSize bytes.

---

- **apiVersion:** v1
- **kind:** Secret
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **data** (map[string][]byte)

Data contains the secret data. Each key must consist of alphanumeric characters, '-', '\_' or '.'. The serialized form of the secret data is a base64 encoded string, representing the arbitrary (possibly non-string) data value here. Described in <https://tools.ietf.org/html/rfc4648#section-4>

- **immutable** (boolean)

Immutable, if set to true, ensures that data stored in the Secret cannot be updated (only object metadata can be modified). If not set to true, the field can be modified at any time. Defaulted to nil.

- **stringData** (map[string]string)

stringData allows specifying non-binary secret data in string form. It is provided as a write-only input field for convenience. All keys and values are merged into the data field on write, overwriting any existing values. The stringData field is never output when reading from the API.

- **type** (string)

Used to facilitate programmatic handling of secret data. More info: <https://kubernetes.io/docs/concepts/configuration/secret/#secret-types>

# SecretList

SecretList is a list of Secret.

---

- **apiVersion:** v1
- **kind:** SecretList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

**items** ([[Secret](#)]), required

- Items is a list of secret objects. More info: <https://kubernetes.io/docs/concepts/configuration/secret>

## Operations

# Volume

Volume represents a named volume in a pod that may be accessed by any container in the pod.

```
import "k8s.io/api/core/v1"
```

## Volume

Volume represents a named volume in a pod that may be accessed by any container in the pod.

- 
- **name** (string), required

name of the volume. Must be a DNS\_LABEL and unique within the pod. More info:  
<https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

## Exposed Persistent volumes

- **persistentVolumeClaim** (PersistentVolumeClaimVolumeSource)

`persistentVolumeClaimVolumeSource` represents a reference to a `PersistentVolumeClaim` in the same namespace. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistentvolumeclaims>

*PersistentVolumeClaimVolumeSource references the user's PVC in the same namespace. This volume finds the bound PV and mounts that volume for the pod. A PersistentVolumeClaimVolumeSource is, essentially, a wrapper around another type of volume that is owned by someone else (the system).*

- **persistentVolumeClaim.claimName** (string), required

`claimName` is the name of a `PersistentVolumeClaim` in the same namespace as the pod using this volume. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistentvolumeclaims>

- **persistentVolumeClaim.readOnly** (boolean)

`readOnly` Will force the `ReadOnly` setting in `VolumeMounts`. Default false.

## Projections

- **configMap** (ConfigMapVolumeSource)

configMap represents a configMap that should populate this volume

\*Adapts a ConfigMap into a volume.

The contents of the target ConfigMap's Data field will be presented in a volume as files using the keys in the Data field as the file names, unless the items element is populated with specific mappings of keys to paths. ConfigMap volumes support ownership management and SELinux relabeling.\*

- **configMap.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **configMap.optional** (boolean)

optional specify whether the ConfigMap or its keys must be defined

- **configMap.defaultMode** (int32)

defaultMode is optional: mode bits used to set permissions on created files by default. Must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. Defaults to 0644. Directories within the path are not affected by this setting. This might be in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.

- **configMap.items** ([][KeyToPath](#))

items if unspecified, each key-value pair in the Data field of the referenced ConfigMap will be projected into the volume as a file whose name is the key and content is the value. If specified, the listed keys will be projected into the specified paths, and unlisted keys will not be present. If a key is specified which is not present in the ConfigMap, the volume setup will error unless it is marked optional. Paths must be relative and may not contain the '..' path or start with '..'.

- **secret** (SecretVolumeSource)

secret represents a secret that should populate this volume. More info: <https://kubernetes.io/docs/concepts/storage/volumes#secret>

\*Adapts a Secret into a volume.

The contents of the target Secret's Data field will be presented in a volume as files using the keys in the Data field as the file names. Secret volumes support ownership management and SELinux relabeling.\*

- **secret.secretName** (string)

secretName is the name of the secret in the pod's namespace to use. More info: <https://kubernetes.io/docs/concepts/storage/volumes#secret>

**secret.optional** (boolean)

- optional field specify whether the Secret or its keys must be defined
- **secret.defaultMode** (int32)

defaultMode is Optional: mode bits used to set permissions on created files by default. Must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. Defaults to 0644. Directories within the path are not affected by this setting. This might be in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.

- **secret.items** ([][KeyToPath](#))

items If unspecified, each key-value pair in the Data field of the referenced Secret will be projected into the volume as a file whose name is the key and content is the value. If specified, the listed keys will be projected into the specified paths, and unlisted keys will not be present. If a key is specified which is not present in the Secret, the volume setup will error unless it is marked optional. Paths must be relative and may not contain the '..' path or start with '..'.

- **downwardAPI** (DownwardAPIVolumeSource)

downwardAPI represents downward API about the pod that should populate this volume

*DownwardAPIVolumeSource represents a volume containing downward API info. Downward API volumes support ownership management and SELinux relabeling.*

- **downwardAPI.defaultMode** (int32)

Optional: mode bits to use on created files by default. Must be a Optional: mode bits used to set permissions on created files by default. Must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. Defaults to 0644. Directories within the path are not affected by this setting. This might be in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.

- **downwardAPI.items** ([][DownwardAPIVolumeFile](#))

Items is a list of downward API volume file

- **projected** (ProjectedVolumeSource)

projected items for all in one resources secrets, configmaps, and downward API

*Represents a projected volume source*

- **projected.defaultMode** (int32)

defaultMode are the mode bits used to set permissions on created files by default. Must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. Directories within the path are not affected by this setting. This might be

in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.

- **projected.sources** ([]VolumeProjection)

sources is the list of volume projections

*Projection that may be projected along with other supported volume types*

- **projected.sources.configMap** (ConfigMapProjection)

configMap information about the configMap data to project

\*Adapts a ConfigMap into a projected volume.

The contents of the target ConfigMap's Data field will be presented in a projected volume as files using the keys in the Data field as the file names, unless the items element is populated with specific mappings of keys to paths. Note that this is identical to a configmap volume source without the default mode.\*

- **projected.sources.configMap.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **projected.sources.configMap.optional** (boolean)

optional specify whether the ConfigMap or its keys must be defined

- **projected.sources.configMap.items** ([][KeyToPath](#))

items if unspecified, each key-value pair in the Data field of the referenced ConfigMap will be projected into the volume as a file whose name is the key and content is the value. If specified, the listed keys will be projected into the specified paths, and unlisted keys will not be present. If a key is specified which is not present in the ConfigMap, the volume setup will error unless it is marked optional. Paths must be relative and may not contain the '..' path or start with '..'.

- **projected.sources.downwardAPI** (DownwardAPIProjection)

downwardAPI information about the downwardAPI data to project

*Represents downward API info for projecting into a projected volume. Note that this is identical to a downwardAPI volume source without the default mode.*

- **projected.sources.downwardAPI.items**  
([][DownwardAPIVolumeFile](#))

Items is a list of DownwardAPIVolume file

- **projected.sources.secret** (SecretProjection)

secret information about the secret data to project

\*Adapts a secret into a projected volume.

The contents of the target Secret's Data field will be presented in a projected volume as files using the keys in the Data field as the file names. Note that this is identical to a secret volume source without the default mode.\*

- **projected.sources.secret.name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **projected.sources.secret.optional** (boolean)

optional field specify whether the Secret or its key must be defined

- **projected.sources.secret.items** ([][KeyToPath](#))

items if unspecified, each key-value pair in the Data field of the referenced Secret will be projected into the volume as a file whose name is the key and content is the value. If specified, the listed keys will be projected into the specified paths, and unlisted keys will not be present. If a key is specified which is not present in the Secret, the volume setup will error unless it is marked optional. Paths must be relative and may not contain the '..' path or start with '..'.

- **projected.sources.serviceAccountToken**  
(ServiceAccountTokenProjection)

serviceAccountToken is information about the serviceAccountToken data to project

*ServiceAccountTokenProjection represents a projected service account token volume. This projection can be used to insert a service account token into the pods runtime filesystem for use against APIs (Kubernetes API Server or otherwise).*

- **projected.sources.serviceAccountToken.path** (string), required

path is the path relative to the mount point of the file to project the token into.

- **projected.sources.serviceAccountToken.audience** (string)

audience is the intended audience of the token. A recipient of a token must identify itself with an identifier specified in the audience of the token, and otherwise should reject the token. The audience defaults to the identifier of the apiserver.

- **projected.sources.serviceAccountToken.expirationSeconds**  
(int64)

expirationSeconds is the requested duration of validity of the service account token. As the token approaches expiration, the kubelet volume plugin will proactively rotate the service account token. The kubelet will start trying to rotate the token if the token is older than 80 percent

of its time to live or if the token is older than 24 hours. Defaults to 1 hour and must be at least 10 minutes.

## Local / Temporary Directory

- **emptyDir** (EmptyDirVolumeSource)

emptyDir represents a temporary directory that shares a pod's lifetime. More info: <https://kubernetes.io/docs/concepts/storage/volumes#emptydir>

*Represents an empty directory for a pod. Empty directory volumes support ownership management and SELinux relabeling.*

- **emptyDir.medium** (string)

medium represents what type of storage medium should back this directory. The default is "" which means to use the node's default medium. Must be an empty string (default) or Memory. More info: <https://kubernetes.io/docs/concepts/storage/volumes#emptydir>

- **emptyDir.sizeLimit** ([Quantity](#))

sizeLimit is the total amount of local storage required for this EmptyDir volume. The size limit is also applicable for memory medium. The maximum usage on memory medium EmptyDir would be the minimum value between the SizeLimit specified here and the sum of memory limits of all containers in a pod. The default is nil which means that the limit is undefined. More info: <https://kubernetes.io/docs/concepts/storage/volumes#emptydir>

- **hostPath** (HostPathVolumeSource)

hostPath represents a pre-existing file or directory on the host machine that is directly exposed to the container. This is generally used for system agents or other privileged things that are allowed to see the host machine. Most containers will NOT need this. More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

*Represents a host path mapped into a pod. Host path volumes do not support ownership management or SELinux relabeling.*

- **hostPath.path** (string), required

path of the directory on the host. If the path is a symlink, it will follow the link to the real path. More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

- **hostPath.type** (string)

type for HostPath Volume Defaults to "" More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

## Persistent volumes

- **awsElasticBlockStore** (AWSElasticBlockStoreVolumeSource)

`awsElasticBlockStore` represents an AWS Disk resource that is attached to a kubelet's host machine and then exposed to the pod. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

\*Represents a Persistent Disk resource in AWS.

An AWS EBS disk must exist before mounting to a container. The disk must also be in the same AWS zone as the kubelet. An AWS EBS disk can only be mounted as read/write once. AWS EBS volumes support ownership management and SELinux relabeling.\*

- **`awsElasticBlockStore.volumeID`** (string), required

`volumeID` is unique ID of the persistent disk resource in AWS (Amazon EBS volume). More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **`awsElasticBlockStore.fsType`** (string)

`fsType` is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **`awsElasticBlockStore.partition`** (int32)

`partition` is the partition in the volume that you want to mount. If omitted, the default is to mount by volume name. Examples: For volume `/dev/sda1`, you specify the partition as "1". Similarly, the volume partition for `/dev/sda` is "0" (or you can leave the property empty).

- **`awsElasticBlockStore.readOnly`** (boolean)

`readOnly` value true will force the `readOnly` setting in `VolumeMounts`. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **`azureDisk`** (AzureDiskVolumeSource)

`azureDisk` represents an Azure Data Disk mount on the host and bind mount to the pod.

*AzureDisk represents an Azure Data Disk mount on the host and bind mount to the pod.*

- **`azureDisk.diskName`** (string), required

`diskName` is the Name of the data disk in the blob storage

- **`azureDisk.diskURI`** (string), required

`diskURI` is the URI of data disk in the blob storage

- **`azureDisk.cachingMode`** (string)

`cachingMode` is the Host Caching mode: None, Read Only, Read Write.

- **`azureDisk.fsType`** (string)

fsType is Filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **azureDisk.kind** (string)

kind expected values are Shared: multiple blob disks per storage account Dedicated: single blob disk per storage account Managed: azure managed data disk (only in managed availability set). defaults to shared

- **azureDisk.readOnly** (boolean)

readOnly Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **azureFile** (AzureFileVolumeSource)

azureFile represents an Azure File Service mount on the host and bind mount to the pod.

*AzureFile represents an Azure File Service mount on the host and bind mount to the pod.*

- **azureFile.secretName** (string), required

secretName is the name of secret that contains Azure Storage Account Name and Key

- **azureFile.shareName** (string), required

shareName is the azure share Name

- **azureFile.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **cephfs** (CephFSVolumeSource)

cephFS represents a Ceph FS mount on the host that shares a pod's lifetime

*Represents a Ceph Filesystem mount that lasts the lifetime of a pod Cephfs volumes do not support ownership management or SELinux relabeling.*

- **cephfs.monitors** ([]string), required

monitors is Required: Monitors is a collection of Ceph monitors More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cephfs.path** (string)

path is Optional: Used as the mounted root, rather than the full Ceph tree, default is /

- **cephfs.readOnly** (boolean)

readOnly is Optional: Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts. More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cephfs.secretFile** (string)

secretFile is Optional: SecretFile is the path to key ring for User, default is /etc/ceph/user.secret More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cephfs.secretRef** ([LocalObjectReference](#))

secretRef is Optional: SecretRef is reference to the authentication secret for User, default is empty. More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cephfs.user** (string)

user is optional: User is the rados user name, default is admin More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cinder** (CinderVolumeSource)

cinder represents a cinder volume attached and mounted on kubelets host machine. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

*Represents a cinder volume resource in Openstack. A Cinder volume must exist before mounting to a container. The volume must also be in the same region as the kubelet. Cinder volumes support ownership management and SELinux relabeling.*

- **cinder.volumeID** (string), required

volumeID used to identify the volume in cinder. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.secretRef** ([LocalObjectReference](#))

secretRef is optional: points to a secret object containing parameters used to connect to OpenStack.

- **csi** (CSIVolumeSource)

csi (Container Storage Interface) represents ephemeral storage that is handled by certain external CSI drivers (Beta feature).

*Represents a source location of a volume to mount, managed by an external CSI driver*

- **csi.driver** (string), required

driver is the name of the CSI driver that handles this volume. Consult with your admin for the correct name as registered in the cluster.

- **csi.fsType** (string)

fsType to mount. Ex. "ext4", "xfs", "ntfs". If not provided, the empty value is passed to the associated CSI driver which will determine the default filesystem to apply.

- **csi.nodePublishSecretRef** ([LocalObjectReference](#))

nodePublishSecretRef is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the CSI NodePublishVolume and NodeUnpublishVolume calls. This field is optional, and may be empty if no secret is required. If the secret object contains more than one secret, all secret references are passed.

- **csi.readOnly** (boolean)

readOnly specifies a read-only configuration for the volume. Defaults to false (read/write).

- **csi.volumeAttributes** (map[string]string)

volumeAttributes stores driver-specific properties that are passed to the CSI driver. Consult your driver's documentation for supported values.

- **ephemeral** (EphemeralVolumeSource)

ephemeral represents a volume that is handled by a cluster storage driver. The volume's lifecycle is tied to the pod that defines it - it will be created before the pod starts, and deleted when the pod is removed.

Use this if: a) the volume is only needed while the pod runs, b) features of normal volumes like restoring from snapshot or capacity tracking are needed, c) the storage driver is specified through a storage class, and d) the storage driver supports dynamic volume provisioning through a PersistentVolumeClaim (see EphemeralVolumeSource for more information on the connection between this volume type and PersistentVolumeClaim).

Use PersistentVolumeClaim or one of the vendor-specific APIs for volumes that persist for longer than the lifecycle of an individual pod.

Use CSI for light-weight local ephemeral volumes if the CSI driver is meant to be used that way - see the documentation of the driver for more information.

A pod can use both types of ephemeral volumes and persistent volumes at the same time.

*Represents an ephemeral volume that is handled by a normal storage driver.*

- **ephemeral.volumeClaimTemplate** ([PersistentVolumeClaimTemplate](#))

Will be used to create a stand-alone PVC to provision the volume. The pod in which this EphemeralVolumeSource is embedded will be the owner of the PVC, i.e. the PVC will be deleted together with the pod. The name of the PVC will be \<pod name>-\<volume name> where \<volume name> is the name from the PodSpec.Volumes array entry. Pod validation will reject the pod if the concatenated name is not valid for a PVC (for example, too long).

An existing PVC with that name that is not owned by the pod will *not* be used for the pod to avoid using an unrelated volume by mistake. Starting the pod is then blocked until the unrelated PVC is removed. If such a pre-created PVC is meant to be used by the pod, the PVC has to be updated with an owner reference to the pod once the pod exists. Normally this should not be necessary, but it may be useful when manually reconstructing a broken cluster.

This field is read-only and no changes will be made by Kubernetes to the PVC after it has been created.

Required, must not be nil.

*PersistentVolumeClaimTemplate is used to produce PersistentVolumeClaim objects as part of an EphemeralVolumeSource.*

- **ephemeral.volumeClaimTemplate.spec** ([PersistentVolumeClaimSpec](#)), required

The specification for the PersistentVolumeClaim. The entire content is copied unchanged into the PVC that gets created from this template. The same fields as in a PersistentVolumeClaim are also valid here.

- **ephemeral.volumeClaimTemplate.metadata** ([ObjectMeta](#))

May contain labels and annotations that will be copied into the PVC when creating it. No other fields are allowed and will be rejected during validation.

- **fc** ([FCVolumeSource](#))

fc represents a Fibre Channel resource that is attached to a kubelet's host machine and then exposed to the pod.

*Represents a Fibre Channel volume. Fibre Channel volumes can only be mounted as read/write once. Fibre Channel volumes support ownership management and SELinux relabeling.*

- **fc.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **fc.lun** (int32)

lun is Optional: FC target lun number

◦ **fc.readOnly** (boolean)

readOnly is Optional: Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

◦ **fc.targetWWNs** ([]string)

targetWWNs is Optional: FC target worldwide names (WWNs)

◦ **fc.wwids** ([]string)

wwids Optional: FC volume world wide identifiers (wwids) Either wwids or combination of targetWWNs and lun must be set, but not both simultaneously.

• **flexVolume** (FlexVolumeSource)

flexVolume represents a generic volume resource that is provisioned/attached using an exec based plugin.

*FlexVolume represents a generic volume resource that is provisioned/attached using an exec based plugin.*

◦ **flexVolume.driver** (string), required

driver is the name of the driver to use for this volume.

◦ **flexVolume.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". The default filesystem depends on FlexVolume script.

◦ **flexVolume.options** (map[string]string)

options is Optional: this field holds extra command options if any.

◦ **flexVolume.readOnly** (boolean)

readOnly is Optional: defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

◦ **flexVolume.secretRef** ([LocalObjectReference](#))

secretRef is Optional: secretRef is reference to the secret object containing sensitive information to pass to the plugin scripts. This may be empty if no secret object is specified. If the secret object contains more than one secret, all secrets are passed to the plugin scripts.

• **flocker** (FlockerVolumeSource)

flocker represents a Flocker volume attached to a kubelet's host machine. This depends on the Flocker control service being running

*Represents a Flocker volume mounted by the Flocker agent. One and only one of `datasetName` and `datasetUUID` should be set. Flocker volumes do not support ownership management or SELinux relabeling.*

- **flocker.datasetName** (string)

`datasetName` is Name of the dataset stored as metadata -> name on the dataset for Flocker should be considered as deprecated

- **flocker.datasetUUID** (string)

`datasetUUID` is the UUID of the dataset. This is unique identifier of a Flocker dataset

- **gcePersistentDisk** (GCEPersistentDiskVolumeSource)

`gcePersistentDisk` represents a GCE Disk resource that is attached to a kubelet's host machine and then exposed to the pod. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

\*Represents a Persistent Disk resource in Google Compute Engine.

A GCE PD must exist before mounting to a container. The disk must also be in the same GCE project and zone as the kubelet. A GCE PD can only be mounted as read/write once or read-only many times. GCE PDs support ownership management and SELinux relabeling.\*

- **gcePersistentDisk.pdName** (string), required

`pdName` is unique name of the PD resource in GCE. Used to identify the disk in GCE. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.fsType** (string)

`fsType` is filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.partition** (int32)

`partition` is the partition in the volume that you want to mount. If omitted, the default is to mount by volume name. Examples: For volume `/dev/sda1`, you specify the partition as "1". Similarly, the volume partition for `/dev/sda` is "0" (or you can leave the property empty). More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.readOnly** (boolean)

`readOnly` here will force the `ReadOnly` setting in `VolumeMounts`. Defaults to false. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **glusterfs** (GlusterfsVolumeSource)

glusterfs represents a Glusterfs mount on the host that shares a pod's lifetime. More info: <https://examples.k8s.io/volumes/glusterfs/README.md>

*Represents a Glusterfs mount that lasts the lifetime of a pod. Glusterfs volumes do not support ownership management or SELinux relabeling.*

- **glusterfs.endpoints** (string), required

endpoints is the endpoint name that details Glusterfs topology. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **glusterfs.path** (string), required

path is the Glusterfs volume path. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **glusterfs.readOnly** (boolean)

readOnly here will force the Glusterfs volume to be mounted with read-only permissions. Defaults to false. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **iscsi** (ISCSIVolumeSource)

iscsi represents an iSCSI Disk resource that is attached to a kubelet's host machine and then exposed to the pod. More info: <https://examples.k8s.io/volumes/iscsi/README.md>

*Represents an iSCSI disk. iSCSI volumes can only be mounted as read/write once. iSCSI volumes support ownership management and SELinux relabeling.*

- **iscsi.iqn** (string), required

iqn is the target iSCSI Qualified Name.

- **iscsi.lun** (int32), required

lun represents iSCSI Target Lun number.

- **iscsi.targetPortal** (string), required

targetPortal is iSCSI Target Portal. The Portal is either an IP or ip\_addr:port if the port is other than default (typically TCP ports 860 and 3260).

- **iscsi.chapAuthDiscovery** (boolean)

chapAuthDiscovery defines whether support iSCSI Discovery CHAP authentication

- **iscsi.chapAuthSession** (boolean)

chapAuthSession defines whether support iSCSI Session CHAP authentication

- **iscsi.fsType** (string)

fsType is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples:

"ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#iscsi>

- **iscsi.initiatorName** (string)

initiatorName is the custom iSCSI Initiator Name. If initiatorName is specified with iscsiInterface simultaneously, new iSCSI interface <target portal>:<volume name> will be created for the connection.

- **iscsi.iscsiInterface** (string)

iscsiInterface is the interface Name that uses an iSCSI transport. Defaults to 'default' (tcp).

- **iscsi.portals** ([]string)

portals is the iSCSI Target Portal List. The portal is either an IP or ip\_addr:port if the port is other than default (typically TCP ports 860 and 3260).

- **iscsi.readOnly** (boolean)

readOnly here will force the ReadOnly setting in VolumeMounts. Defaults to false.

- **iscsi.secretRef** ([LocalObjectReference](#))

secretRef is the CHAP Secret for iSCSI target and initiator authentication

- **nfs** (NFSVolumeSource)

nfs represents an NFS mount on the host that shares a pod's lifetime More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

*Represents an NFS mount that lasts the lifetime of a pod. NFS volumes do not support ownership management or SELinux relabeling.*

- **nfs.path** (string), required

path that is exported by the NFS server. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

- **nfs.server** (string), required

server is the hostname or IP address of the NFS server. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

- **nfs.readOnly** (boolean)

readOnly here will force the NFS export to be mounted with read-only permissions. Defaults to false. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

- **photonPersistentDisk** (PhotonPersistentDiskVolumeSource)

photonPersistentDisk represents a PhotonController persistent disk attached and mounted on kubelets host machine

*Represents a Photon Controller persistent disk resource.*

- **photonPersistentDisk.pdID** (string), required

pdID is the ID that identifies Photon Controller persistent disk

- **photonPersistentDisk.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **portworxVolume** (PortworxVolumeSource)

portworxVolume represents a portworx volume attached and mounted on kubelets host machine

*PortworxVolumeSource represents a Portworx volume resource.*

- **portworxVolume.volumeID** (string), required

volumeID uniquely identifies a Portworx volume

- **portworxVolume.fsType** (string)

fsType represents the filesystem type to mount Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs". Implicitly inferred to be "ext4" if unspecified.

- **portworxVolume.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **quobyte** (QuobyteVolumeSource)

quobyte represents a Quobyte mount on the host that shares a pod's lifetime

*Represents a Quobyte mount that lasts the lifetime of a pod. Quobyte volumes do not support ownership management or SELinux relabeling.*

- **quobyte.registry** (string), required

registry represents a single or multiple Quobyte Registry services specified as a string as host:port pair (multiple entries are separated with commas) which acts as the central registry for volumes

- **quobyte.volume** (string), required

volume is a string that references an already created Quobyte volume by name.

- **quobyte.group** (string)

group to map volume access to Default is no group

- **quobyte.readOnly** (boolean)

readOnly here will force the Quobyte volume to be mounted with read-only permissions. Defaults to false.

- **quobyte.tenant** (string)

tenant owning the given Quobyte volume in the Backend Used with dynamically provisioned Quobyte volumes, value is set by the plugin

- **quobyte.user** (string)

user to map volume access to Defaults to serviceaccount user

- **rbd** (RBDVolumeSource)

rbd represents a Rados Block Device mount on the host that shares a pod's lifetime. More info: <https://examples.k8s.io/volumes/rbd/README.md>

*Represents a Rados Block Device mount that lasts the lifetime of a pod. RBD volumes support ownership management and SELinux relabeling.*

- **rbd.image** (string), required

image is the rados image name. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.monitors** ([]string), required

monitors is a collection of Ceph monitors. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.fsType** (string)

fsType is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#rbd>

- **rbd.keyring** (string)

keyring is the path to key ring for RBDUser. Default is /etc/ceph/keyring. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.pool** (string)

pool is the rados pool name. Default is rbd. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.readOnly** (boolean)

readOnly here will force the ReadOnly setting in VolumeMounts. Defaults to false. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.secretRef** ([LocalObjectReference](#))

secretRef is name of the authentication secret for RBDUser. If provided overrides keyring. Default is nil. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **rbd.user** (string)

user is the rados user name. Default is admin. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **scaleIO** (ScaleIOVolumeSource)

scaleIO represents a ScaleIO persistent volume attached and mounted on Kubernetes nodes.

*ScaleIOVolumeSource represents a persistent ScaleIO volume*

- **scaleIO.gateway** (string), required

gateway is the host address of the ScaleIO API Gateway.

- **scaleIO.secretRef** ([LocalObjectReference](#)), required

secretRef references to the secret for ScaleIO user and other sensitive information. If this is not provided, Login operation will fail.

- **scaleIO.system** (string), required

system is the name of the storage system as configured in ScaleIO.

- **scaleIO.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Default is "xfs".

- **scaleIO.protectionDomain** (string)

protectionDomain is the name of the ScaleIO Protection Domain for the configured storage.

- **scaleIO.readOnly** (boolean)

readOnly Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **scaleIO.sslEnabled** (boolean)

sslEnabled Flag enable/disable SSL communication with Gateway, default false

- **scaleIO.storageMode** (string)

storageMode indicates whether the storage for a volume should be ThickProvisioned or ThinProvisioned. Default is ThinProvisioned.

- **scaleIO.storagePool** (string)

storagePool is the ScaleIO Storage Pool associated with the protection domain.

**scaleIO.volumeName** (string)

- volumeName is the name of a volume already created in the ScaleIO system that is associated with this volume source.

- **storageos** (StorageOSVolumeSource)

storageOS represents a StorageOS volume attached and mounted on Kubernetes nodes.

*Represents a StorageOS persistent volume resource.*

- **storageos.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **storageos.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **storageos.secretRef** ([LocalObjectReference](#))

secretRef specifies the secret to use for obtaining the StorageOS API credentials. If not specified, default values will be attempted.

- **storageos.volumeName** (string)

volumeName is the human-readable name of the StorageOS volume. Volume names are only unique within a namespace.

- **storageos.volumeNamespace** (string)

volumeNamespace specifies the scope of the volume within StorageOS. If no namespace is specified then the Pod's namespace will be used. This allows the Kubernetes name scoping to be mirrored within StorageOS for tighter integration. Set VolumeName to any name to override the default behaviour. Set to "default" if you are not using namespaces within StorageOS. Namespaces that do not pre-exist within StorageOS will be created.

- **vsphereVolume** (VsphereVirtualDiskVolumeSource)

vsphereVolume represents a vSphere volume attached and mounted on kubelets host machine

*Represents a vSphere volume resource.*

- **vsphereVolume.volumePath** (string), required

volumePath is the path that identifies vSphere volume vmdk

- **vsphereVolume.fsType** (string)

fsType is filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **vsphereVolume.storagePolicyID** (string)

storagePolicyID is the storage Policy Based Management (SPBM) profile ID associated with the StoragePolicyName.

- **vsphereVolume.storagePolicyName** (string)

storagePolicyName is the storage Policy Based Management (SPBM) profile name.

## Deprecated

- **gitRepo** (GitRepoVolumeSource)

gitRepo represents a git repository at a particular revision. DEPRECATED: GitRepo is deprecated. To provision a container with a git repo, mount an EmptyDir into an InitContainer that clones the repo using git, then mount the EmptyDir into the Pod's container.

\*Represents a volume that is populated with the contents of a git repository. Git repo volumes do not support ownership management. Git repo volumes support SELinux relabeling.

DEPRECATED: GitRepo is deprecated. To provision a container with a git repo, mount an EmptyDir into an InitContainer that clones the repo using git, then mount the EmptyDir into the Pod's container.\*

- **gitRepo.repository** (string), required

repository is the URL

- **gitRepo.directory** (string)

directory is the target directory name. Must not contain or start with '..'. If '' is supplied, the volume directory will be the git repository. Otherwise, if specified, the volume will contain the git repository in the subdirectory with the given name.

- **gitRepo.revision** (string)

revision is the commit hash for the specified revision.

## DownwardAPIVolumeFile

DownwardAPIVolumeFile represents information to create the file containing the pod field

---

- **path** (string), required

Required: Path is the relative path name of the file to be created. Must not be absolute or contain the '..' path. Must be utf-8 encoded. The first item of the relative path must not start with '..'

**fieldRef** ([ObjectFieldSelector](#))

- Required: Selects a field of the pod: only annotations, labels, name and namespace are supported.
- **mode** (int32)  
  
Optional: mode bits used to set permissions on this file, must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. If not specified, the volume defaultMode will be used. This might be in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.
- **resourceFieldRef** ([ResourceFieldSelector](#))  
  
Selects a resource of the container: only resources limits and requests (limits.cpu, limits.memory, requests.cpu and requests.memory) are currently supported.

## KeyToPath

Maps a string key to a path within a volume.

---

- **key** (string), required  
  
key is the key to project.
- **path** (string), required  
  
path is the relative path of the file to map the key to. May not be an absolute path. May not contain the path element '..'. May not start with the string '..'.
- **mode** (int32)  
  
mode is Optional: mode bits used to set permissions on this file. Must be an octal value between 0000 and 0777 or a decimal value between 0 and 511. YAML accepts both octal and decimal values, JSON requires decimal values for mode bits. If not specified, the volume defaultMode will be used. This might be in conflict with other options that affect the file mode, like fsGroup, and the result can be other mode bits set.

## PersistentVolumeClaim

PersistentVolumeClaim is a user's request for and claim to a persistent volume.

apiVersion: v1

import "k8s.io/api/core/v1"

## PersistentVolumeClaim

PersistentVolumeClaim is a user's request for and claim to a persistent volume

- 
- **apiVersion:** v1
  - **kind:** PersistentVolumeClaim
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PersistentVolumeClaimSpec](#))

spec defines the desired characteristics of a volume requested by a pod author. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistentvolumeclaims>

- **status** ([PersistentVolumeClaimStatus](#))

status represents the current information/status of a persistent volume claim. Read-only. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistentvolumeclaims>

## PersistentVolumeClaimSpec

PersistentVolumeClaimSpec describes the common attributes of storage devices and allows a Source for provider-specific attributes

---

- **accessModes** ([]string)

accessModes contains the desired access modes the volume should have. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#access-modes-1>

- **selector** ([LabelSelector](#))

selector is a label query over volumes to consider for binding.

- **resources** (ResourceRequirements)

resources represents the minimum resources the volume should have. If RecoverVolumeExpansionFailure feature is enabled users are allowed to specify resource requirements that are lower than previous value but must still be higher than capacity recorded in the status field of the claim. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#resources>

*ResourceRequirements describes the compute resource requirements.*

- **resources.claims** ([]ResourceClaim)

*Map: unique values on key name will be kept during a merge*

Claims lists the names of resources, defined in spec.resourceClaims, that are used by this container.

This is an alpha field and requires enabling the `DynamicResourceAllocation` feature gate.

This field is immutable. It can only be set for containers.

*ResourceClaim references one entry in PodSpec.ResourceClaims.*

- **resources.claims.name** (string), required

Name must match the name of one entry in `pod.spec.resourceClaims` of the Pod where this field is used. It makes that resource available inside a container.

- **resources.limits** (map[string][Quantity](#))

Limits describes the maximum amount of compute resources allowed. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

- **resources.requests** (map[string][Quantity](#))

Requests describes the minimum amount of compute resources required. If Requests is omitted for a container, it defaults to Limits if that is explicitly specified, otherwise to an implementation-defined value. Requests cannot exceed Limits. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

- **volumeName** (string)

volumeName is the binding reference to the PersistentVolume backing this claim.

- **storageClassName** (string)

storageClassName is the name of the StorageClass required by the claim. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#class-1>

- **volumeMode** (string)

volumeMode defines what type of volume is required by the claim. Value of Filesystem is implied when not included in claim spec.

## Beta level

- **dataSource** ([TypedLocalObjectReference](#))

dataSource field can be used to specify either: \* An existing VolumeSnapshot object (snapshot.storage.k8s.io/VolumeSnapshot) \* An existing PVC (PersistentVolumeClaim) If the provisioner or an external controller can support the specified data source, it will create a new volume based on the contents of the specified data source. When the AnyVolumeDataSource feature gate is enabled, dataSource contents will be copied to dataSourceRef, and dataSourceRef contents will be copied to dataSource when dataSourceRef.namespace is not specified. If the namespace is specified, then dataSourceRef will not be copied to dataSource.

- **dataSourceRef** (TypedObjectReference)

`dataSourceRef` specifies the object from which to populate the volume with data, if a non-empty volume is desired. This may be any object from a non-empty API group (non core object) or a `PersistentVolumeClaim` object. When this field is specified, volume binding will only succeed if the type of the specified object matches some installed volume populator or dynamic provisioner. This field will replace the functionality of the `dataSource` field and as such if both fields are non-empty, they must have the same value. For backwards compatibility, when namespace isn't specified in `dataSourceRef`, both fields (`dataSource` and `dataSourceRef`) will be set to the same value automatically if one of them is empty and the other is non-empty. When namespace is specified in `dataSourceRef`, `dataSource` isn't set to the same value and must be empty. There are three important differences between `dataSource` and `dataSourceRef`: \* While `dataSource` only allows two specific types of objects, `dataSourceRef` allows any non-core object, as well as `PersistentVolumeClaim` objects.

- While `dataSource` ignores disallowed values (dropping them), `dataSourceRef` preserves all values, and generates an error if a disallowed value is specified.
- While `dataSource` only allows local objects, `dataSourceRef` allows objects in any namespaces. (Beta) Using this field requires the `AnyVolumeDataSource` feature gate to be enabled. (Alpha) Using the namespace field of `dataSourceRef` requires the `CrossNamespaceVolumeDataSource` feature gate to be enabled.

\*\*

- **`dataSourceRef.kind`** (string), required

Kind is the type of resource being referenced

- **`dataSourceRef.name`** (string), required

Name is the name of resource being referenced

- **`dataSourceRef.apiGroup`** (string)

APIGroup is the group for the resource being referenced. If APIGroup is not specified, the specified Kind must be in the core API group. For any other third-party types, APIGroup is required.

- **`dataSourceRef.namespace`** (string)

Namespace is the namespace of resource being referenced Note that when a namespace is specified, a `gateway.networking.k8s.io/ReferenceGrant` object is required in the referent namespace to allow that namespace's owner to accept the reference. See the `ReferenceGrant` documentation for details. (Alpha) This field requires the `CrossNamespaceVolumeDataSource` feature gate to be enabled.

## PersistentVolumeClaimStatus

`PersistentVolumeClaimStatus` is the current status of a persistent volume claim.

- 
- **`accessModes`** ([]string)

`accessModes` contains the actual access modes the volume backing the PVC has. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#access-modes-1>

## **allocatedResourceStatuses** (map[string]string)

allocatedResourceStatuses stores status of resource being resized for the given PVC. Key names follow standard Kubernetes label syntax. Valid values are either: \* Un-prefixed keys: - storage - the capacity of the volume. \* Custom resources must use implementation-defined prefixed names such as "example.com/my-custom-resource". Apart from above values - keys that are unprefixed or have kubernetes.io prefix are considered reserved and hence may not be used.

ClaimResourceStatus can be in any of following states: - ControllerResizeInProgress: State set when resize controller starts resizing the volume in control-plane. - ControllerResizeFailed: State set when resize has failed in resize controller with a terminal error. - NodeResizePending: State set when resize controller has finished resizing the volume but further resizing of volume is needed on the node. - NodeResizeInProgress: State set when kubelet starts resizing the volume. - NodeResizeFailed: State set when resizing has failed in kubelet with a terminal error. Transient errors don't set NodeResizeFailed. For example: if expanding a PVC for more capacity - this field can be one of the following states: - pvc.status.allocatedResourceStatus['storage'] = "ControllerResizeInProgress" - pvc.status.allocatedResourceStatus['storage'] = "ControllerResizeFailed" - pvc.status.allocatedResourceStatus['storage'] = "NodeResizePending" - pvc.status.allocatedResourceStatus['storage'] = "NodeResizeInProgress" - pvc.status.allocatedResourceStatus['storage'] = "NodeResizeFailed" When this field is not set, it means that no resize operation is in progress for the given PVC.

A controller that receives PVC update with previously unknown resourceName or ClaimResourceStatus should ignore the update for the purpose it was designed. For example - a controller that only is responsible for resizing capacity of the volume, should ignore PVC updates that change other valid resources associated with PVC.

This is an alpha field and requires enabling RecoverVolumeExpansionFailure feature.

## • **allocatedResources** (map[string>[Quantity](#))

allocatedResources tracks the resources allocated to a PVC including its capacity. Key names follow standard Kubernetes label syntax. Valid values are either: \* Un-prefixed keys: - storage - the capacity of the volume. \* Custom resources must use implementation-defined prefixed names such as "example.com/my-custom-resource". Apart from above values - keys that are unprefixed or have kubernetes.io prefix are considered reserved and hence may not be used.

Capacity reported here may be larger than the actual capacity when a volume expansion operation is requested. For storage quota, the larger value from allocatedResources and PVC.spec.resources is used. If allocatedResources is not set, PVC.spec.resources alone is used for quota calculation. If a volume expansion capacity request is lowered, allocatedResources is only lowered if there are no expansion operations in progress and if the actual volume capacity is equal or lower than the requested capacity.

A controller that receives PVC update with previously unknown resourceName should ignore the update for the purpose it was designed. For example - a controller that only is responsible for resizing capacity of the volume, should ignore PVC updates that change other valid resources associated with PVC.

This is an alpha field and requires enabling RecoverVolumeExpansionFailure feature.

• **capacity** (map[string][Quantity](#))

• capacity represents the actual resources of the underlying volume.

• **conditions** ([]PersistentVolumeClaimCondition)

*Patch strategy: merge on key type*

conditions is the current Condition of persistent volume claim. If underlying persistent volume is being resized then the Condition will be set to 'ResizeStarted'.

*PersistentVolumeClaimCondition contains details about state of pvc*

◦ **conditions.status** (string), required

◦ **conditions.type** (string), required

◦ **conditions.lastProbeTime** (Time)

lastProbeTime is the time we probed the condition.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

◦ **conditions.lastTransitionTime** (Time)

lastTransitionTime is the time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

◦ **conditions.message** (string)

message is the human-readable message indicating details about last transition.

◦ **conditions.reason** (string)

reason is a unique, this should be a short, machine understandable string that gives the reason for condition's last transition. If it reports "ResizeStarted" that means the underlying persistent volume is being resized.

• **phase** (string)

phase represents the current phase of PersistentVolumeClaim.

## PersistentVolumeClaimList

PersistentVolumeClaimList is a list of PersistentVolumeClaim items.

---

• **apiVersion**: v1

**kind:** PersistentVolumeClaimList

- 
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]PersistentVolumeClaim](#)), required

items is a list of persistent volume claims. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistentvolumeclaims>

## Operations

---

### get read the specified PersistentVolumeClaim

#### HTTP Request

GET /api/v1/namespaces/{namespace}/persistentvolumeclaims/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the PersistentVolumeClaim
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([PersistentVolumeClaim](#)): OK

401: Unauthorized

### get read status of the specified PersistentVolumeClaim

#### HTTP Request

GET /api/v1/namespaces/{namespace}/persistentvolumeclaims/{name}/status

#### Parameters

- **name** (*in path*): string, required

name of the PersistentVolumeClaim

- **namespace** (*in path*): string, required

[namespace](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([PersistentVolumeClaim](#)): OK

401: Unauthorized

## list list or watch objects of kind PersistentVolumeClaim

### HTTP Request

GET /api/v1/namespaces/{namespace}/persistentvolumeclaims

### Parameters

- **namespace** (*in path*): string, required

[namespace](#)

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

- **pretty** (*in query*): string

[pretty](#)

- **resourceVersion** (*in query*): string

[resourceVersion](#)

- **resourceVersionMatch** (*in query*): string

[resourceVersionMatch](#)

- **sendInitialEvents** (*in query*): boolean

[sendInitialEvents](#)

- **timeoutSeconds** (*in query*): integer

[timeoutSeconds](#)

- **watch** (*in query*): boolean

[watch](#)

## Response

200 ([PersistentVolumeClaimList](#)): OK

401: Unauthorized

## list list or watch objects of kind PersistentVolumeClaim

## HTTP Request

GET /api/v1/persistentvolumeclaims

## Parameters

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

[fieldSelector](#)

- **labelSelector** (*in query*): string

[labelSelector](#)

- **limit** (*in query*): integer

[limit](#)

- **pretty** (*in query*): string

[pretty](#)

- **resourceVersion** (*in query*): string

[resourceVersion](#)

- **resourceVersionMatch** (*in query*): string

[resourceVersionMatch](#)

- **sendInitialEvents** (*in query*): boolean

[sendInitialEvents](#)

- **timeoutSeconds** (*in query*): integer

[timeoutSeconds](#)

- **watch** (*in query*): boolean

[watch](#)

## Response

200 ([PersistentVolumeClaimList](#)): OK

401: Unauthorized

## create create a PersistentVolumeClaim

### HTTP Request

POST /api/v1/namespaces/{namespace}/persistentvolumeclaims

### Parameters

- **namespace** (*in path*): string, required

[namespace](#)

- **body**: [PersistentVolumeClaim](#), required

- **dryRun** (*in query*): string

[dryRun](#)

- **fieldManager** (*in query*): string

[fieldManager](#)

- **fieldValidation** (*in query*): string

[fieldValidation](#)

- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([PersistentVolumeClaim](#)): OK

201 ([PersistentVolumeClaim](#)): Created

202 ([PersistentVolumeClaim](#)): Accepted

401: Unauthorized

## update replace the specified PersistentVolumeClaim

### HTTP Request

PUT /api/v1/namespaces/{namespace}/persistentvolumeclaims/{name}

### Parameters

- **name** (*in path*): string, required  
name of the PersistentVolumeClaim
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [PersistentVolumeClaim](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)

# PersistentVolume

PersistentVolume (PV) is a storage resource provisioned by an administrator.

apiVersion: v1

import "k8s.io/api/core/v1"

## PersistentVolume

PersistentVolume (PV) is a storage resource provisioned by an administrator. It is analogous to a node. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes>

- 
- **apiVersion**: v1
  - **kind**: PersistentVolume
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PersistentVolumeSpec](#))

spec defines a specification of a persistent volume owned by the cluster. Provisioned by an administrator. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistent-volumes>

- **status** ([PersistentVolumeStatus](#))

status represents the current information/status for the persistent volume. Populated by the system. Read-only. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#persistent-volumes>

## PersistentVolumeSpec

PersistentVolumeSpec is the specification of a persistent volume.

---

- **accessModes** ([]string)

accessModes contains all ways the volume can be mounted. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#access-modes>

- **capacity** (map[string][Quantity](#))

capacity is the description of the persistent volume's resources and capacity. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#capacity>

- **claimRef** ([ObjectReference](#))

claimRef is part of a bi-directional binding between PersistentVolume and PersistentVolumeClaim. Expected to be non-nil when bound. claim.VolumeName is the authoritative bind between PV and PVC. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#binding>

- **mountOptions** ([]string)

mountOptions is the list of mount options, e.g. ["ro", "soft"]. Not validated - mount will simply fail if one is invalid. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes/#mount-options>

- **nodeAffinity** (VolumeNodeAffinity)

nodeAffinity defines constraints that limit what nodes this volume can be accessed from. This field influences the scheduling of pods that use this volume.

*VolumeNodeAffinity defines constraints that limit what nodes this volume can be accessed from.*

- **nodeAffinity.required** (NodeSelector)

required specifies hard node constraints that must be met.

*A node selector represents the union of the results of one or more label queries over a set of nodes; that is, it represents the OR of the selectors represented by the node selector terms.*

- **nodeAffinity.required.nodeSelectorTerms** ([]NodeSelectorTerm), required

Required. A list of node selector terms. The terms are ORed.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **nodeAffinity.required.nodeSelectorTerms.matchExpressions**  
([]NodeSelectorRequirement)

A list of node selector requirements by node's labels.

- **nodeAffinity.required.nodeSelectorTerms.matchFields**  
([]NodeSelectorRequirement)

A list of node selector requirements by node's fields.

- **persistentVolumeReclaimPolicy** (string)

`persistentVolumeReclaimPolicy` defines what happens to a persistent volume when released from its claim. Valid options are Retain (default for manually created PersistentVolumes), Delete (default for dynamically provisioned PersistentVolumes), and Recycle (deprecated). Recycle must be supported by the volume plugin underlying this PersistentVolume. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#reclaiming>

- **storageClassName** (string)

`storageClassName` is the name of StorageClass to which this persistent volume belongs. Empty value means that this volume does not belong to any StorageClass.

- **volumeMode** (string)

`volumeMode` defines if a volume is intended to be used with a formatted filesystem or to remain in raw block state. Value of Filesystem is implied when not included in spec.

## Local

- **hostPath** (HostPathVolumeSource)

`hostPath` represents a directory on the host. Provisioned by a developer or tester. This is useful for single-node development and testing only! On-host storage is not supported in any way and WILL NOT WORK in a multi-node cluster. More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

*Represents a host path mapped into a pod. Host path volumes do not support ownership management or SELinux relabeling.*

- **hostPath.path** (string), required

path of the directory on the host. If the path is a symlink, it will follow the link to the real path. More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

- **hostPath.type** (string)

type for HostPath Volume Defaults to "" More info: <https://kubernetes.io/docs/concepts/storage/volumes#hostpath>

- **local** (LocalVolumeSource)

local represents directly-attached storage with node affinity

*Local represents directly-attached storage with node affinity (Beta feature)*

- **local.path** (string), required

path of the full path to the volume on the node. It can be either a directory or block device (disk, partition, ...).

- **local.fsType** (string)

fsType is the filesystem type to mount. It applies only when the Path is a block device. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". The default value is to auto-select a filesystem if unspecified.

## Persistent volumes

- **awsElasticBlockStore** (AWSElasticBlockStoreVolumeSource)

awsElasticBlockStore represents an AWS Disk resource that is attached to a kubelet's host machine and then exposed to the pod. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

\*Represents a Persistent Disk resource in AWS.

An AWS EBS disk must exist before mounting to a container. The disk must also be in the same AWS zone as the kubelet. An AWS EBS disk can only be mounted as read/write once. AWS EBS volumes support ownership management and SELinux relabeling.\*

- **awsElasticBlockStore.volumeID** (string), required

volumeID is unique ID of the persistent disk resource in AWS (Amazon EBS volume). More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **awsElasticBlockStore.fsType** (string)

fsType is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **awsElasticBlockStore.partition** (int32)

partition is the partition in the volume that you want to mount. If omitted, the default is to mount by volume name. Examples: For volume /dev/sda1, you specify the partition as "1". Similarly, the volume partition for /dev/sda is "0" (or you can leave the property empty).

- **awsElasticBlockStore.readOnly** (boolean)

readOnly value true will force the readOnly setting in VolumeMounts. More info: <https://kubernetes.io/docs/concepts/storage/volumes#awselasticblockstore>

- **azureDisk** (AzureDiskVolumeSource)

azureDisk represents an Azure Data Disk mount on the host and bind mount to the pod.

*AzureDisk represents an Azure Data Disk mount on the host and bind mount to the pod.*

- **azureDisk.diskName** (string), required

diskName is the Name of the data disk in the blob storage

- **azureDisk.diskURI** (string), required

diskURI is the URI of data disk in the blob storage

- **azureDisk.cachingMode** (string)

cachingMode is the Host Caching mode: None, Read Only, Read Write.

- **azureDisk.fsType** (string)

fsType is Filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **azureDisk.kind** (string)

kind expected values are Shared: multiple blob disks per storage account Dedicated: single blob disk per storage account Managed: azure managed data disk (only in managed availability set). defaults to shared

- **azureDisk.readOnly** (boolean)

readOnly Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **azureFile** (AzureFilePersistentVolumeSource)

azureFile represents an Azure File Service mount on the host and bind mount to the pod.

*AzureFile represents an Azure File Service mount on the host and bind mount to the pod.*

- **azureFile.secretName** (string), required

secretName is the name of secret that contains Azure Storage Account Name and Key

**azureFile.shareName** (string), required

- shareName is the azure Share Name

◦ **azureFile.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

◦ **azureFile.secretNamespace** (string)

secretNamespace is the namespace of the secret that contains Azure Storage Account Name and Key default is the same as the Pod

- **cephfs** (CephFSPersistentVolumeSource)

cephFS represents a Ceph FS mount on the host that shares a pod's lifetime

*Represents a Ceph Filesystem mount that lasts the lifetime of a pod Cephfs volumes do not support ownership management or SELinux relabeling.*

◦ **cephfs.monitors** ([]string), required

monitors is Required: Monitors is a collection of Ceph monitors More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

◦ **cephfs.path** (string)

path is Optional: Used as the mounted root, rather than the full Ceph tree, default is /

◦ **cephfs.readOnly** (boolean)

readOnly is Optional: Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts. More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

◦ **cephfs.secretFile** (string)

secretFile is Optional: SecretFile is the path to key ring for User, default is /etc/ceph/user.secret More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

◦ **cephfs.secretRef** (SecretReference)

secretRef is Optional: SecretRef is reference to the authentication secret for User, default is empty. More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **cephfs.secretRef.name** (string)

name is unique within a namespace to reference a secret resource.

- **cephfs.secretRef.namespace** (string)

- namespace defines the space within which the secret name must be unique.

- **cephfs.user** (string)

- user is Optional: User is the rados user name, default is admin More info: <https://examples.k8s.io/volumes/cephfs/README.md#how-to-use-it>

- **cinder** (CinderPersistentVolumeSource)

cinder represents a cinder volume attached and mounted on kubelets host machine. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

*Represents a cinder volume resource in Openstack. A Cinder volume must exist before mounting to a container. The volume must also be in the same region as the kubelet. Cinder volumes support ownership management and SELinux relabeling.*

- **cinder.volumeID** (string), required

- volumeID used to identify the volume in cinder. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.fsType** (string)

- fsType Filesystem type to mount. Must be a filesystem type supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.readOnly** (boolean)

- readOnly is Optional: Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts. More info: <https://examples.k8s.io/mysql-cinder-pd/README.md>

- **cinder.secretRef** (SecretReference)

- secretRef is Optional: points to a secret object containing parameters used to connect to OpenStack.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **cinder.secretRef.name** (string)

- name is unique within a namespace to reference a secret resource.

- **cinder.secretRef.namespace** (string)

- namespace defines the space within which the secret name must be unique.

- **csi** (CSIPersistentVolumeSource)

csi represents storage that is handled by an external CSI driver (Beta feature).

*Represents storage that is managed by an external CSI volume driver (Beta feature)*

- **csi.driver** (string), required

driver is the name of the driver to use for this volume. Required.

- **csi.volumeHandle** (string), required

volumeHandle is the unique volume name returned by the CSI volume plugin's CreateVolume to refer to the volume on all subsequent calls. Required.

- **csi.controllerExpandSecretRef** (SecretReference)

controllerExpandSecretRef is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the CSI ControllerExpandVolume call. This field is optional, and may be empty if no secret is required. If the secret object contains more than one secret, all secrets are passed.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **csi.controllerExpandSecretRef.name** (string)

name is unique within a namespace to reference a secret resource.

- **csi.controllerExpandSecretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

- **csi.controllerPublishSecretRef** (SecretReference)

controllerPublishSecretRef is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the CSI ControllerPublishVolume and ControllerUnpublishVolume calls. This field is optional, and may be empty if no secret is required. If the secret object contains more than one secret, all secrets are passed.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **csi.controllerPublishSecretRef.name** (string)

name is unique within a namespace to reference a secret resource.

- **csi.controllerPublishSecretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

- **csi.fsType** (string)

fsType to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs".

- **csi.nodeExpandSecretRef** (SecretReference)

`nodeExpandSecretRef` is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the `CSI NodeExpandVolume` call. This is a beta field which is enabled default by `CSINodeExpandSecret` feature gate. This field is optional, may be omitted if no secret is required. If the secret object contains more than one secret, all secrets are passed.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **`csi.nodeExpandSecretRef.name`** (string)

name is unique within a namespace to reference a secret resource.

- **`csi.nodeExpandSecretRef.namespace`** (string)

namespace defines the space within which the secret name must be unique.

- **`csi.nodePublishSecretRef`** (SecretReference)

`nodePublishSecretRef` is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the `CSI NodePublishVolume` and `NodeUnpublishVolume` calls. This field is optional, and may be empty if no secret is required. If the secret object contains more than one secret, all secrets are passed.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **`csi.nodePublishSecretRef.name`** (string)

name is unique within a namespace to reference a secret resource.

- **`csi.nodePublishSecretRef.namespace`** (string)

namespace defines the space within which the secret name must be unique.

- **`csi.nodeStageSecretRef`** (SecretReference)

`nodeStageSecretRef` is a reference to the secret object containing sensitive information to pass to the CSI driver to complete the `CSI NodeStageVolume` and `NodeUnstageVolume` calls. This field is optional, and may be empty if no secret is required. If the secret object contains more than one secret, all secrets are passed.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **`csi.nodeStageSecretRef.name`** (string)

name is unique within a namespace to reference a secret resource.

- **`csi.nodeStageSecretRef.namespace`** (string)

namespace defines the space within which the secret name must be unique.

- **`csi.readOnly`** (boolean)

readOnly value to pass to ControllerPublishVolumeRequest. Defaults to false (read/write).

- **csi.volumeAttributes** (map[string]string)

volumeAttributes of the volume to publish.

- **fc** (FCVolumeSource)

fc represents a Fibre Channel resource that is attached to a kubelet's host machine and then exposed to the pod.

*Represents a Fibre Channel volume. Fibre Channel volumes can only be mounted as read/write once. Fibre Channel volumes support ownership management and SELinux relabeling.*

- **fc.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **fc.lun** (int32)

lun is Optional: FC target lun number

- **fc.readOnly** (boolean)

readOnly is Optional: Defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **fc.targetWWNs** ([]string)

targetWWNs is Optional: FC target worldwide names (WWNs)

- **fc.wwids** ([]string)

wwids Optional: FC volume world wide identifiers (wwids) Either wwids or combination of targetWWNs and lun must be set, but not both simultaneously.

- **flexVolume** (FlexPersistentVolumeSource)

flexVolume represents a generic volume resource that is provisioned/attached using an exec based plugin.

*FlexPersistentVolumeSource represents a generic persistent volume resource that is provisioned/attached using an exec based plugin.*

- **flexVolume.driver** (string), required

driver is the name of the driver to use for this volume.

- **flexVolume.fsType** (string)

fsType is the Filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". The default filesystem depends on FlexVolume script.

**flexVolume.options** (map[string]string)

- options is Optional: this field holds extra command options if any.

◦ **flexVolume.readOnly** (boolean)

readOnly is Optional: defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

◦ **flexVolume.secretRef** (SecretReference)

secretRef is Optional: SecretRef is reference to the secret object containing sensitive information to pass to the plugin scripts. This may be empty if no secret object is specified. If the secret object contains more than one secret, all secrets are passed to the plugin scripts.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

▪ **flexVolume.secretRef.name** (string)

name is unique within a namespace to reference a secret resource.

▪ **flexVolume.secretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

• **flocker** (FlockerVolumeSource)

flocker represents a Flocker volume attached to a kubelet's host machine and exposed to the pod for its usage. This depends on the Flocker control service being running

*Represents a Flocker volume mounted by the Flocker agent. One and only one of datasetName and datasetUUID should be set. Flocker volumes do not support ownership management or SELinux relabeling.*

◦ **flocker.datasetName** (string)

datasetName is Name of the dataset stored as metadata -> name on the dataset for Flocker should be considered as deprecated

◦ **flocker.datasetUUID** (string)

datasetUUID is the UUID of the dataset. This is unique identifier of a Flocker dataset

• **gcePersistentDisk** (GCEPersistentDiskVolumeSource)

gcePersistentDisk represents a GCE Disk resource that is attached to a kubelet's host machine and then exposed to the pod. Provisioned by an admin. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

\*Represents a Persistent Disk resource in Google Compute Engine.

A GCE PD must exist before mounting to a container. The disk must also be in the same GCE project and zone as the kubelet. A GCE PD can only be mounted as read/write once or read-only many times. GCE PDs support ownership management and SELinux relabeling.\*

- **gcePersistentDisk.pdName** (string), required

pdName is unique name of the PD resource in GCE. Used to identify the disk in GCE. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.fsType** (string)

fsType is filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.partition** (int32)

partition is the partition in the volume that you want to mount. If omitted, the default is to mount by volume name. Examples: For volume /dev/sda1, you specify the partition as "1". Similarly, the volume partition for /dev/sda is "0" (or you can leave the property empty). More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **gcePersistentDisk.readOnly** (boolean)

readOnly here will force the ReadOnly setting in VolumeMounts. Defaults to false. More info: <https://kubernetes.io/docs/concepts/storage/volumes#gcepersistentdisk>

- **glusterfs** (GlusterfsPersistentVolumeSource)

glusterfs represents a Glusterfs volume that is attached to a host and exposed to the pod. Provisioned by an admin. More info: <https://examples.k8s.io/volumes/glusterfs/README.md>

*Represents a Glusterfs mount that lasts the lifetime of a pod. Glusterfs volumes do not support ownership management or SELinux relabeling.*

- **glusterfs.endpoints** (string), required

endpoints is the endpoint name that details Glusterfs topology. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **glusterfs.path** (string), required

path is the Glusterfs volume path. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **glusterfs.endpointsNamespace** (string)

endpointsNamespace is the namespace that contains Glusterfs endpoint. If this field is empty, the EndpointNamespace defaults to the same namespace as the bound

PVC. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **glusterfs.readOnly** (boolean)

readOnly here will force the Glusterfs volume to be mounted with read-only permissions. Defaults to false. More info: <https://examples.k8s.io/volumes/glusterfs/README.md#create-a-pod>

- **iscsi** (ISCSIPersistentVolumeSource)

iscsi represents an iSCSI Disk resource that is attached to a kubelet's host machine and then exposed to the pod. Provisioned by an admin.

*ISCSIPersistentVolumeSource represents an iSCSI disk. iSCSI volumes can only be mounted as read/write once. iSCSI volumes support ownership management and SELinux relabeling.*

- **iscsi.iqn** (string), required

iqn is Target iSCSI Qualified Name.

- **iscsi.lun** (int32), required

lun is iSCSI Target Lun number.

- **iscsi.targetPortal** (string), required

targetPortal is iSCSI Target Portal. The Portal is either an IP or ip\_addr:port if the port is other than default (typically TCP ports 860 and 3260).

- **iscsi.chapAuthDiscovery** (boolean)

chapAuthDiscovery defines whether support iSCSI Discovery CHAP authentication

- **iscsi.chapAuthSession** (boolean)

chapAuthSession defines whether support iSCSI Session CHAP authentication

- **iscsi.fsType** (string)

fsType is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#iscsi>

- **iscsi.initiatorName** (string)

initiatorName is the custom iSCSI Initiator Name. If initiatorName is specified with iscsiInterface simultaneously, new iSCSI interface <target portal>:<volume name> will be created for the connection.

- **iscsi.iscsiInterface** (string)

iscsiInterface is the interface Name that uses an iSCSI transport. Defaults to 'default' (tcp).

**iscsi.portals** ([]string)

- portals is the iSCSI Target Portal List. The Portal is either an IP or ip\_addr:port if the port is other than default (typically TCP ports 860 and 3260).

◦ **iscsi.readOnly** (boolean)

readOnly here will force the ReadOnly setting in VolumeMounts. Defaults to false.

◦ **iscsi.secretRef** (SecretReference)

secretRef is the CHAP Secret for iSCSI target and initiator authentication

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

▪ **iscsi.secretRef.name** (string)

name is unique within a namespace to reference a secret resource.

▪ **iscsi.secretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

• **nfs** (NFSVolumeSource)

nfs represents an NFS mount on the host. Provisioned by an admin. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

*Represents an NFS mount that lasts the lifetime of a pod. NFS volumes do not support ownership management or SELinux relabeling.*

◦ **nfs.path** (string), required

path that is exported by the NFS server. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

◦ **nfs.server** (string), required

server is the hostname or IP address of the NFS server. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

◦ **nfs.readOnly** (boolean)

readOnly here will force the NFS export to be mounted with read-only permissions. Defaults to false. More info: <https://kubernetes.io/docs/concepts/storage/volumes#nfs>

• **photonPersistentDisk** (PhotonPersistentDiskVolumeSource)

photonPersistentDisk represents a PhotonController persistent disk attached and mounted on kubelets host machine

*Represents a Photon Controller persistent disk resource.*

◦ **photonPersistentDisk.pdID** (string), required

pdID is the ID that identifies Photon Controller persistent disk

- **photonPersistentDisk.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **portworxVolume** (PortworxVolumeSource)

portworxVolume represents a portworx volume attached and mounted on kubelets host machine

*PortworxVolumeSource represents a Portworx volume resource.*

- **portworxVolume.volumeID** (string), required

volumeID uniquely identifies a Portworx volume

- **portworxVolume.fsType** (string)

fsType represents the filesystem type to mount Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs". Implicitly inferred to be "ext4" if unspecified.

- **portworxVolume.readOnly** (boolean)

readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.

- **quobyte** (QuobyteVolumeSource)

quobyte represents a Quobyte mount on the host that shares a pod's lifetime

*Represents a Quobyte mount that lasts the lifetime of a pod. Quobyte volumes do not support ownership management or SELinux relabeling.*

- **quobyte.registry** (string), required

registry represents a single or multiple Quobyte Registry services specified as a string as host:port pair (multiple entries are separated with commas) which acts as the central registry for volumes

- **quobyte.volume** (string), required

volume is a string that references an already created Quobyte volume by name.

- **quobyte.group** (string)

group to map volume access to Default is no group

- **quobyte.readOnly** (boolean)

readOnly here will force the Quobyte volume to be mounted with read-only permissions. Defaults to false.

**quobyte.tenant** (string)

- tenant owning the given Quobyte volume in the Backend Used with dynamically provisioned Quobyte volumes, value is set by the plugin

◦ **quobyte.user** (string)

user to map volume access to Defaults to serviceaccount user

• **rbd** (RBDPersistentVolumeSource)

rbd represents a Rados Block Device mount on the host that shares a pod's lifetime. More info: <https://examples.k8s.io/volumes/rbd/README.md>

*Represents a Rados Block Device mount that lasts the lifetime of a pod. RBD volumes support ownership management and SELinux relabeling.*

◦ **rbd.image** (string), required

image is the rados image name. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

◦ **rbd.monitors** ([]string), required

monitors is a collection of Ceph monitors. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

◦ **rbd.fsType** (string)

fsType is the filesystem type of the volume that you want to mount. Tip: Ensure that the filesystem type is supported by the host operating system. Examples: "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified. More info: <https://kubernetes.io/docs/concepts/storage/volumes#rbd>

◦ **rbd.keyring** (string)

keyring is the path to key ring for RBDUser. Default is /etc/ceph/keyring. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

◦ **rbd.pool** (string)

pool is the rados pool name. Default is rbd. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

◦ **rbd.readOnly** (boolean)

readOnly here will force the ReadOnly setting in VolumeMounts. Defaults to false. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

◦ **rbd.secretRef** (SecretReference)

secretRef is name of the authentication secret for RBDUser. If provided overrides keyring. Default is nil. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **rbd.secretRef.name** (string)

name is unique within a namespace to reference a secret resource.

- **rbd.secretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

- **rbd.user** (string)

user is the rados user name. Default is admin. More info: <https://examples.k8s.io/volumes/rbd/README.md#how-to-use-it>

- **scaleIO** (ScaleIOPersistentVolumeSource)

scaleIO represents a ScaleIO persistent volume attached and mounted on Kubernetes nodes.

*ScaleIOPersistentVolumeSource represents a persistent ScaleIO volume*

- **scaleIO.gateway** (string), required

gateway is the host address of the ScaleIO API Gateway.

- **scaleIO.secretRef** (SecretReference), required

secretRef references to the secret for ScaleIO user and other sensitive information. If this is not provided, Login operation will fail.

*SecretReference represents a Secret Reference. It has enough information to retrieve secret in any namespace*

- **scaleIO.secretRef.name** (string)

name is unique within a namespace to reference a secret resource.

- **scaleIO.secretRef.namespace** (string)

namespace defines the space within which the secret name must be unique.

- **scaleIO.system** (string), required

system is the name of the storage system as configured in ScaleIO.

- **scaleIO.fsType** (string)

fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Default is "xfs"

- **scaleIO.protectionDomain** (string)

protectionDomain is the name of the ScaleIO Protection Domain for the configured storage.

- **scaleIO.readOnly** (boolean)
  - readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.
- **scaleIO.sslEnabled** (boolean)
  - sslEnabled is the flag to enable/disable SSL communication with Gateway, default false
- **scaleIO.storageMode** (string)
  - storageMode indicates whether the storage for a volume should be ThickProvisioned or ThinProvisioned. Default is ThinProvisioned.
- **scaleIO.storagePool** (string)
  - storagePool is the ScaleIO Storage Pool associated with the protection domain.
- **scaleIO.volumeName** (string)
  - volumeName is the name of a volume already created in the ScaleIO system that is associated with this volume source.
- **storageos** (StorageOSPersistentVolumeSource)
  - storageOS represents a StorageOS volume that is attached to the kubelet's host machine and mounted into the pod More info: <https://examples.k8s.io/volumes/storageos/README.md>
  - *Represents a StorageOS persistent volume resource.*
  - **storageos.fsType** (string)
    - fsType is the filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.
  - **storageos.readOnly** (boolean)
    - readOnly defaults to false (read/write). ReadOnly here will force the ReadOnly setting in VolumeMounts.
  - **storageos.secretRef** ([ObjectReference](#))
    - secretRef specifies the secret to use for obtaining the StorageOS API credentials. If not specified, default values will be attempted.
  - **storageos.volumeName** (string)
    - volumeName is the human-readable name of the StorageOS volume. Volume names are only unique within a namespace.
  - **storageos.volumeNamespace** (string)

`volumeNamespace` specifies the scope of the volume within StorageOS. If no namespace is specified then the Pod's namespace will be used. This allows the Kubernetes name scoping to be mirrored within StorageOS for tighter integration. Set `VolumeName` to any name to override the default behaviour. Set to "default" if you are not using namespaces within StorageOS. Namespaces that do not pre-exist within StorageOS will be created.

- **vsphereVolume** (VsphereVirtualDiskVolumeSource)

`vsphereVolume` represents a vSphere volume attached and mounted on kubelets host machine

*Represents a vSphere volume resource.*

- **vsphereVolume.volumePath** (string), required

`volumePath` is the path that identifies vSphere volume vmdk

- **vsphereVolume.fsType** (string)

`fsType` is filesystem type to mount. Must be a filesystem type supported by the host operating system. Ex. "ext4", "xfs", "ntfs". Implicitly inferred to be "ext4" if unspecified.

- **vsphereVolume.storagePolicyID** (string)

`storagePolicyID` is the storage Policy Based Management (SPBM) profile ID associated with the `StoragePolicyName`.

- **vsphereVolume.storagePolicyName** (string)

`storagePolicyName` is the storage Policy Based Management (SPBM) profile name.

## PersistentVolumeStatus

`PersistentVolumeStatus` is the current status of a persistent volume.

---

- **lastPhaseTransitionTime** (Time)

`lastPhaseTransitionTime` is the time the phase transitioned from one to another and automatically resets to current time everytime a volume phase transitions. This is an alpha field and requires enabling `PersistentVolumeLastPhaseTransitionTime` feature.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **message** (string)

`message` is a human-readable message indicating details about why the volume is in this state.

- **phase** (string)

phase indicates if a volume is available, bound to a claim, or released by a claim. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#phase>

- **reason** (string)

reason is a brief CamelCase string that describes any failure and is meant for machine parsing and tidy display in the CLI.

## PersistentVolumeList

PersistentVolumeList is a list of PersistentVolume items.

---

- **apiVersion**: v1
- **kind**: PersistentVolumeList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]PersistentVolume](#)), required

items is a list of persistent volumes. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes>

## Operations

---

### get read the specified PersistentVolume

#### HTTP Request

GET /api/v1/persistentvolumes/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the PersistentVolume
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([PersistentVolume](#)): OK

401: Unauthorized

## get read status of the specified PersistentVolume

### HTTP Request

GET /api/v1/persistentvolumes/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the PersistentVolume
- **pretty** (*in query*): string

[pretty](#)

### Response

200 ([PersistentVolume](#)): OK

401: Unauthorized

## list list or watch objects of kind PersistentVolume

### HTTP Request

GET /api/v1/persistentvolumes

### Parameters

- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)

- **continue** (*in query*): string  
[continue](#)

- **fieldSelector** (*in query*): string  
[fieldSelector](#)

- **labelSelector** (*in query*): string

[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([PersistentVolume](#)): OK

201 ([PersistentVolume](#)): Created

401: Unauthorized

## update replace status of the specified PersistentVolume

### HTTP Request

PUT /api/v1/persistentvolumes/{name}/status

## Parameters

- **name** (*in path*): string, required  
name of the PersistentVolume
- **body**: [PersistentVolume](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([PersistentVolume](#)): OK

201 ([PersistentVolume](#)): Created

401: Unauthorized

## patch partially update the specified PersistentVolume

### HTTP Request

PATCH /api/v1/persistentvolumes/{name}

## Parameters

- **name** (*in path*): string, required  
name of the PersistentVolume
- **body**: [Patch](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)

- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **force** (*in query*): boolean  
[force](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([PersistentVolume](#)): OK

201 ([PersistentVolume](#)): Created

401: Unauthorized

## patch partially update status of the specified PersistentVolume

### HTTP Request

PATCH /api/v1/persistentvolumes/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the PersistentVolume
- **body**: [Patch](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **force** (*in query*): boolean

[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)

## Response

200 ([Status](#)): OK

# StorageClass

StorageClass describes the parameters for a class of storage for which PersistentVolumes can be dynamically provisioned.

apiVersion: storage.k8s.io/v1

```
import "k8s.io/api/storage/v1"
```

## StorageClass

StorageClass describes the parameters for a class of storage for which PersistentVolumes can be dynamically provisioned.

StorageClasses are non-namespaced; the name of the storage class according to etcd is in ObjectMeta.Name.

- 
- **apiVersion:** storage.k8s.io/v1

- **kind:** StorageClass

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **provisioner** (string), required

provisioner indicates the type of the provisioner.

- **allowVolumeExpansion** (boolean)

allowVolumeExpansion shows whether the storage class allow volume expand.

- **allowedTopologies** ([]TopologySelectorTerm)

*Atomic: will be replaced during a merge*

allowedTopologies restrict the node topologies where volumes can be dynamically provisioned. Each volume plugin defines its own supported topology specifications. An empty TopologySelectorTerm list means there is no topology restriction. This field is only honored by servers that enable the VolumeScheduling feature.

*A topology selector term represents the result of label queries. A null or empty topology selector term matches no objects. The requirements of them are ANDed. It provides a subset of functionality as NodeSelectorTerm. This is an alpha feature and may change in the future.*

- **allowedTopologies.matchLabelExpressions**  
([]TopologySelectorLabelRequirement)

A list of topology selector requirements by labels.

*A topology selector requirement is a selector that matches given label. This is an alpha feature and may change in the future.*

- **allowedTopologies.matchLabelExpressions.key** (string), required

The label key that the selector applies to.

- **allowedTopologies.matchLabelExpressions.values** ([]string), required

An array of string values. One value must match the label to be selected.  
Each entry in Values is ORed.

- **mountOptions** ([]string)

mountOptions controls the mountOptions for dynamically provisioned PersistentVolumes of this storage class. e.g. ["ro", "soft"]. Not validated - mount of the PVs will simply fail if one is invalid.

- **parameters** (map[string]string)

parameters holds the parameters for the provisioner that should create volumes of this storage class.

- **reclaimPolicy** (string)

reclaimPolicy controls the reclaimPolicy for dynamically provisioned PersistentVolumes of this storage class. Defaults to Delete.

- **volumeBindingMode** (string)

volumeBindingMode indicates how PersistentVolumeClaims should be provisioned and bound. When unset, VolumeBindingImmediate is used. This field is only honored by servers that enable the VolumeScheduling feature.

## StorageClassList

StorageClassList is a collection of storage classes.

- 
- **apiVersion:** storage.k8s.io/v1
  - **kind:** StorageClassList
  - **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([][StorageClass](#)), required

items is the list of StorageClasses

# Operations

---

## get read the specified StorageClass

### HTTP Request

GET /apis/storage.k8s.io/v1/storageclasses/{name}

### Parameters

- **name** (*in path*): string, required  
name of the StorageClass
- **pretty** (*in query*): string

[pretty](#)

### Response

200 ([StorageClass](#)): OK

401: Unauthorized

## list list or watch objects of kind StorageClass

# VolumeAttachment

VolumeAttachment captures the intent to attach or detach the specified volume to/from the specified node.

apiVersion: storage.k8s.io/v1

```
import "k8s.io/api/storage/v1"
```

## VolumeAttachment

VolumeAttachment captures the intent to attach or detach the specified volume to/from the specified node.

VolumeAttachment objects are non-namespaced.

- 
- **apiVersion:** storage.k8s.io/v1

- **kind:** VolumeAttachment

- **metadata** ([ObjectMeta](#))

Standard object metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([VolumeAttachmentSpec](#)), required

spec represents specification of the desired attach/detach volume behavior. Populated by the Kubernetes system.

- **status** ([VolumeAttachmentStatus](#))

status represents status of the VolumeAttachment request. Populated by the entity completing the attach or detach operation, i.e. the external-attacher.

## VolumeAttachmentSpec

VolumeAttachmentSpec is the specification of a VolumeAttachment request.

---

- **attacher** (string), required

attacher indicates the name of the volume driver that MUST handle this request. This is the name returned by GetPluginName().

- **nodeName** (string), required

nodeName represents the node that the volume should be attached to.

- **source** (VolumeAttachmentSource), required

source represents the volume that should be attached.

*VolumeAttachmentSource represents a volume that should be attached. Right now only PersistentVolumes can be attached via external attacher, in future we may allow also inline volumes in pods. Exactly one member can be set.*

- **source.inlineVolumeSpec** ([PersistentVolumeSpec](#))

inlineVolumeSpec contains all the information necessary to attach a persistent volume defined by a pod's inline VolumeSource. This field is populated only for the CSIMigration feature. It contains translated fields from a pod's inline VolumeSource to a PersistentVolumeSpec. This field is beta-level and is only honored by servers that enabled the CSIMigration feature.

- **source.persistentVolumeName** (string)

persistentVolumeName represents the name of the persistent volume to attach.

# VolumeAttachmentStatus

VolumeAttachmentStatus is the status of a VolumeAttachment request.

---

- **attached** (boolean), required

attached indicates the volume is successfully attached. This field must only be set by the entity completing the attach operation, i.e. the external-attacher.

- **attachError** (VolumeError)

attachError represents the last error encountered during attach operation, if any. This field must only be set by the entity completing the attach operation, i.e. the external-attacher.

*VolumeError captures an error encountered during a volume operation.*

- **attachError.message** (string)

message represents the error encountered during Attach or Detach operation. This string may be logged, so it should not contain sensitive information.

- **attachError.time** (Time)

time represents the time the error was encountered.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **attachmentMetadata** (map[string]string)

attachmentMetadata is populated with any information returned by the attach operation, upon successful attach, that must be passed into subsequent WaitForAttach or Mount calls. This field must only be set by the entity completing the attach operation, i.e. the external-attacher.

- **detachError** (VolumeError)

detachError represents the last error encountered during detach operation, if any. This field must only be set by the entity completing the detach operation, i.e. the external-attacher.

*VolumeError captures an error encountered during a volume operation.*

- **detachError.message** (string)

message represents the error encountered during Attach or Detach operation. This string may be logged, so it should not contain sensitive information.

- **detachError.time** (Time)

time represents the time the error was encountered.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

## VolumeAttachmentList

VolumeAttachmentList is a collection of VolumeAttachment objects.

---

- **apiVersion:** storage.k8s.io/v1

- **kind:** VolumeAttachmentList

- **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]VolumeAttachment](#)), required

items is the list of VolumeAttachments

## Operations

---

### get read the specified VolumeAttachment

#### HTTP Request

GET /apis/storage.k8s.io/v1/volumeattachments/{name}

#### Parameters

# CSIDriver

CSIDriver captures information about a Container Storage Interface (CSI) volume driver deployed on the cluster.

apiVersion: storage.k8s.io/v1

```
import "k8s.io/api/storage/v1"
```

## CSIDriver

CSIDriver captures information about a Container Storage Interface (CSI) volume driver deployed on the cluster. Kubernetes attach detach controller uses this object to determine whether attach is required. Kubelet uses this object to determine whether pod information needs to be passed on mount. CSIDriver objects are non-namespaced.

- 
- **apiVersion:** storage.k8s.io/v1
  - **kind:** CSIDriver
  - **metadata** ([ObjectMeta](#))

Standard object metadata. metadata.Name indicates the name of the CSI driver that this object refers to; it MUST be the same name returned by the CSI GetPluginName() call for that driver. The driver name must be 63 characters or less, beginning and ending with an alphanumeric character ([a-z0-9A-Z]) with dashes (-), dots (.), and alphanumerics between. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([CSIDriverSpec](#)), required

spec represents the specification of the CSI Driver.

## CSIDriverSpec

CSIDriverSpec is the specification of a CSIDriver.

- 
- **attachRequired** (boolean)

attachRequired indicates this CSI volume driver requires an attach operation (because it implements the CSI ControllerPublishVolume() method), and that the Kubernetes attach detach controller should call the attach volume interface which checks the volumeattachment status and waits until the volume is attached before proceeding to mounting. The CSI external-attacher coordinates with CSI volume driver and updates the volumeattachment status when the attach operation is complete. If the CSIDriverRegistry feature gate is enabled and the value is specified to false, the attach operation will be skipped. Otherwise the attach operation will be called.

This field is immutable.

- **fsGroupPolicy** (string)

fsGroupPolicy defines if the underlying volume supports changing ownership and permission of the volume before being mounted. Refer to the specific FSGroupPolicy values for additional details.

This field is immutable.

Defaults to `ReadWriteOnceWithFSType`, which will examine each volume to determine if Kubernetes should modify ownership and permissions of the volume. With the default policy the defined fsGroup will only be applied if a fstype is defined and the volume's access mode contains `ReadWriteOnce`.

- **podInfoOnMount** (boolean)

podInfoOnMount indicates this CSI volume driver requires additional pod information (like podName, podUID, etc.) during mount operations, if set to true. If set to false, pod information will not be passed on mount. Default is false.

The CSI driver specifies podInfoOnMount as part of driver deployment. If true, Kubelet will pass pod information as VolumeContext in the CSI NodePublishVolume() calls. The CSI driver is responsible for parsing and validating the information passed in as VolumeContext.

The following VolumeContext will be passed if podInfoOnMount is set to true. This list might grow, but the prefix will be used. "csi.storage.k8s.io/pod.name": pod.Name "csi.storage.k8s.io/pod.namespace": pod.Namespace "csi.storage.k8s.io/pod.uid": string(pod.UID) "csi.storage.k8s.io/ephemeral": "true" if the volume is an ephemeral inline volume defined by a CSIVolumeSource, otherwise "false"

"csi.storage.k8s.io/ephemeral" is a new feature in Kubernetes 1.16. It is only required for drivers which support both the "Persistent" and "Ephemeral" VolumeLifecycleMode. Other drivers can leave pod info disabled and/or ignore this field. As Kubernetes 1.15 doesn't support this field, drivers can only support one mode when deployed on such a cluster and the deployment determines which mode that is, for example via a command line parameter of the driver.

This field is immutable.

- **requiresRepublish** (boolean)

requiresRepublish indicates the CSI driver wants NodePublishVolume being periodically called to reflect any possible change in the mounted volume. This field defaults to false.

Note: After a successful initial NodePublishVolume call, subsequent calls to NodePublishVolume should only update the contents of the volume. New mount points will not be seen by a running container.

- **seLinuxMount** (boolean)

seLinuxMount specifies if the CSI driver supports "-o context" mount option.

When "true", the CSI driver must ensure that all volumes provided by this CSI driver can be mounted separately with different `-o` context options. This is typical for storage backends that provide volumes as filesystems on block devices or as independent shared volumes. Kubernetes will call `NodeStage / NodePublish` with `"-o context=xyz"` mount option when mounting a `ReadWriteOncePod` volume used in Pod that has explicitly set SELinux context. In the future, it may be expanded to other volume `AccessModes`. In any case, Kubernetes will ensure that the volume is mounted only with a single SELinux context.

When "false", Kubernetes won't pass any special SELinux mount options to the driver. This is typical for volumes that represent subdirectories of a bigger shared filesystem.

Default is "false".

- **storageCapacity** (boolean)

`storageCapacity` indicates that the CSI volume driver wants pod scheduling to consider the storage capacity that the driver deployment will report by creating `CSIStorageCapacity` objects with capacity information, if set to true.

The check can be enabled immediately when deploying a driver. In that case, provisioning new volumes with late binding will pause until the driver deployment has published some suitable `CSIStorageCapacity` object.

Alternatively, the driver can be deployed with the field unset or false and it can be flipped later when storage capacity information has been published.

This field was immutable in Kubernetes  $\leq$  1.22 and now is mutable.

- **tokenRequests** (`[]TokenRequest`)

*Atomic: will be replaced during a merge*

`tokenRequests` indicates the CSI driver needs pods' service account tokens it is mounting volume for to do necessary authentication. Kubelet will pass the tokens in `VolumeContext` in the CSI `NodePublishVolume` calls. The CSI driver should parse and validate the following `VolumeContext`: `"csi.storage.k8s.io/serviceAccount.tokens": { "<audience>": { "token": <token>, "expirationTimestamp": <expiration timestamp in RFC3339>, }, ... }`

Note: Audience in each `TokenRequest` should be different and at most one token is empty string. To receive a new token after expiry, `RequiresRepublish` can be used to trigger `NodePublishVolume` periodically.

*TokenRequest contains parameters of a service account token.*

- **tokenRequests.audience** (string), required

audience is the intended audience of the token in `"TokenRequestSpec"`. It will default to the audiences of kube apiserver.

- **tokenRequests.expirationSeconds** (int64)

expirationSeconds is the duration of validity of the token in `"TokenRequestSpec"`. It has the same default value of `"ExpirationSeconds"` in `"TokenRequestSpec"`.

**volumeLifecycleModes** ([]string)

- *Set: unique values will be kept during a merge*

volumeLifecycleModes defines what kind of volumes this CSI volume driver supports. The default if the list is empty is "Persistent", which is the usage defined by the CSI specification and implemented in Kubernetes via the usual PV/PVC mechanism.

The other mode is "Ephemeral". In this mode, volumes are defined inline inside the pod spec with CSIVolumeSource and their lifecycle is tied to the lifecycle of that pod. A driver has to be aware of this because it is only going to get a NodePublishVolume call for such a volume.

For more information about implementing this mode, see <https://kubernetes-csi.github.io/docs/ephemeral-local-volumes.html> A driver can support one or more of these modes and more modes may be added in the future.

This field is beta. This field is immutable.

## CSIDriverList

CSIDriverList is a collection of CSIDriver objects.

- 
- **apiVersion:** storage.k8s.io/v1
  - **kind:** CSIDriverList
  - **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

# CSINode

CSINode holds information about all CSI drivers installed on a node.

apiVersion: storage.k8s.io/v1

import "k8s.io/api/storage/v1"

## CSINode

CSINode holds information about all CSI drivers installed on a node. CSI drivers do not need to create the CSINode object directly. As long as they use the node-driver-registrar sidecar container, the kubelet will automatically populate the CSINode object for the CSI driver as part of kubelet plugin registration. CSINode has the same name as a node. If the object is missing, it means either there are no CSI Drivers available on the node, or the Kubelet version is low enough that it doesn't create this object. CSINode has an OwnerReference that points to the corresponding node object.

- 
- **apiVersion**: storage.k8s.io/v1
  - **kind**: CSINode
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. metadata.name must be the Kubernetes node name.

- **spec** ([CSINodeSpec](#)), required

spec is the specification of CSINode

# CSINodeSpec

CSINodeSpec holds information about the specification of all CSI drivers installed on a node

---

- **drivers** ([]CSINodeDriver), required

*Patch strategy: merge on key name*

drivers is a list of information of all CSI Drivers existing on a node. If all drivers in the list are uninstalled, this can become empty.

*CSINodeDriver holds information about the specification of one CSI driver installed on a node*

- **drivers.name** (string), required

name represents the name of the CSI driver that this object refers to. This MUST be the same name returned by the CSI GetPluginName() call for that driver.

- **drivers.nodeID** (string), required

nodeID of the node from the driver point of view. This field enables Kubernetes to communicate with storage systems that do not share the same nomenclature for nodes. For example, Kubernetes may refer to a given node as "node1", but the storage system may refer to the same node as "nodeA". When Kubernetes issues a command to the storage system to attach a volume to a specific node, it can use this field to refer to the node name using the ID that the storage system will understand, e.g. "nodeA" instead of "node1". This field is required.

- **drivers.allocatable** (VolumeNodeResources)

allocatable represents the volume resources of a node that are available for scheduling. This field is beta.

*VolumeNodeResources is a set of resource limits for scheduling of volumes.*

- **drivers.allocatable.count** (int32)

count indicates the maximum number of unique volumes managed by the CSI driver that can be used on a node. A volume that is both attached and mounted on a node is considered to be used once, not twice. The same rule applies for a unique volume that is shared among multiple pods on the same node. If this field is not specified, then the supported number of volumes on this node is unbounded.

- **drivers.topologyKeys** ([]string)

topologyKeys is the list of keys supported by the driver. When a driver is initialized on a cluster, it provides a set of topology keys that it understands (e.g. "company.com/zone", "company.com/region"). When a driver is initialized on a node, it provides the same topology keys along with values. Kubelet will expose these topology keys as labels on its own node object. When Kubernetes does topology aware provisioning, it can use this list to determine which labels it should

retrieve from the node object and pass back to the driver. It is possible for different nodes to use different topology keys. This can be empty if driver does not support topology.

## CSINodeList

CSINodeList is a collection of CSINode objects.

---

# CSIStorageCapacity

CSIStorageCapacity stores the result of one CSI GetCapacity call.

apiVersion: storage.k8s.io/v1

```
import "k8s.io/api/storage/v1"
```

## CSIStorageCapacity

CSIStorageCapacity stores the result of one CSI GetCapacity call. For a given StorageClass, this describes the available capacity in a particular topology segment. This can be used when considering where to instantiate new PersistentVolumes.

For example this can express things like: - StorageClass "standard" has "1234 GiB" available in "topology.kubernetes.io/zone=us-east1" - StorageClass "localssd" has "10 GiB" available in "kubernetes.io/hostname=knode-abc123"

The following three cases all imply that no capacity is available for a certain combination: - no object exists with suitable topology and storage class name - such an object exists, but the capacity is unset - such an object exists, but the capacity is zero

The producer of these objects can decide which approach is more suitable.

They are consumed by the kube-scheduler when a CSI driver opts into capacity-aware scheduling with CSIDriverSpec.StorageCapacity. The scheduler compares the MaximumVolumeSize against the requested size of pending volumes to filter out unsuitable nodes. If MaximumVolumeSize is unset, it falls back to a comparison against the less precise Capacity. If that is also unset, the scheduler assumes that capacity is insufficient and tries some other node.

- 
- **apiVersion:** storage.k8s.io/v1
  - **kind:** CSIStorageCapacity
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. The name has no particular meaning. It must be a DNS subdomain (dots allowed, 253 characters). To ensure that there are no conflicts with other CSI drivers on the cluster, the recommendation is to use csisc-**<uuid>**, a generated name, or a reverse-domain name which ends with the unique CSI driver name.

Objects are namespaced.

More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **storageClassName** (string), required

storageClassName represents the name of the StorageClass that the reported capacity applies to. It must meet the same requirements as the name of a StorageClass object (non-empty, DNS subdomain). If that object no longer exists, the CSIStorageCapacity object is obsolete and should be removed by its creator. This field is immutable.

- **capacity** ([Quantity](#))

capacity is the value reported by the CSI driver in its GetCapacityResponse for a GetCapacityRequest with topology and parameters that match the previous fields.

The semantic is currently (CSI spec 1.2) defined as: The available capacity, in bytes, of the storage that can be used to provision volumes. If not set, that information is currently unavailable.

- **maximumVolumeSize** ([Quantity](#))

maximumVolumeSize is the value reported by the CSI driver in its GetCapacityResponse for a GetCapacityRequest with topology and parameters that match the previous fields.

This is defined since CSI spec 1.4.0 as the largest size that may be used in a CreateVolumeRequest.capacity\_range.required\_bytes field to create a volume with the same parameters as those in GetCapacityRequest. The corresponding value in the Kubernetes API is ResourceRequirements.Requests in a volume claim.

- **nodeTopology** ([LabelSelector](#))

nodeTopology defines which nodes have access to the storage for which capacity was reported. If not set, the storage is not accessible from any node in the cluster. If empty, the storage is accessible from all nodes. This field is immutable.

## CSIStorageCapacityList

CSIStorageCapacityList is a collection of CSIStorageCapacity objects.

- 
- **apiVersion**: storage.k8s.io/v1
  - **kind**: CSIStorageCapacityList
  - **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]CSIStorageCapacity](#)), required

*Map: unique values on key name will be kept during a merge*

items is the list of CSIStorageCapacity objects.

### HTTP Request

PUT /apis/storage.k8s.io/v1/namespaces/{namespace}/csistoragecapacities/{name}

### Parameters

- **name** (*in path*): string, required  
name of the CSIStorageCapacity
- **namespace** (*in path*): string, required  
[namespace](#)
- **body:** [CSIStorageCapacity](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)

- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([CSISStorageCapacity](#)): OK

201 ([CSISStorageCapacity](#)): Created

401: Unauthorized

## patch partially update the specified CSISStorageCapacity

### HTTP Request

PATCH /apis/storage.k8s.io/v1/namespaces/{namespace}/csistoragecapacities/{name}

### Parameters

- **name** (*in path*): string, required  
name of the CSISStorageCapacity
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [Patch](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **force** (*in query*): boolean  
[force](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([CSIStorageCapacity](#)): OK

201 ([CSIStorageCapacity](#)): Created

401: Unauthorized

## delete delete a CSIStorageCapacity

### HTTP Request

DELETE /apis/storage.k8s.io/v1/namespaces/{namespace}/csistoragecapacities/{name}

### Parameters

- **name** (*in path*): string, required  
name of the CSIStorageCapacity
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [DeleteOptions](#)
- **dryRun** (*in query*): string  
[dryRun](#)
- **gracePeriodSeconds** (*in query*): integer  
[gracePeriodSeconds](#)
- **pretty** (*in query*): string  
[pretty](#)
- **propagationPolicy** (*in query*): string

[propagationPolicy](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)
- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean

[sendInitialEvents](#)

- **timeoutSeconds** (*in query*): integer

[timeoutSeconds](#)

## Response

200 ([Status](#)): OK

401: Unauthorized

# Authentication Resources

---

## [ServiceAccount](#)

ServiceAccount binds together: \* a name, understood by users, and perhaps by peripheral systems, for an identity \* a principal that can be authenticated and authorized \* a set of secrets.

## [TokenRequest](#)

TokenRequest requests a token for a given service account.

## [TokenReview](#)

TokenReview attempts to authenticate a token to a known user.

## [CertificateSigningRequest](#)

CertificateSigningRequest objects provide a mechanism to obtain x509 certificates by submitting a certificate signing request, and having it asynchronously approved and issued.

## [ClusterTrustBundle v1alpha1](#)

ClusterTrustBundle is a cluster-scoped container for X.

## [SelfSubjectReview](#)

SelfSubjectReview contains the user information that the kube-apiserver has about the user making this request.

# ServiceAccount

ServiceAccount binds together: \* a name, understood by users, and perhaps by peripheral systems, for an identity \* a principal that can be authenticated and authorized \* a set of secrets.

apiVersion: v1

```
import "k8s.io/api/core/v1"
```

## ServiceAccount

ServiceAccount binds together: \* a name, understood by users, and perhaps by peripheral systems, for an identity \* a principal that can be authenticated and authorized \* a set of secrets

---

- **apiVersion:** v1
- **kind:** ServiceAccount
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **automountServiceAccountToken** (boolean)

AutomountServiceAccountToken indicates whether pods running as this service account should have an API token automatically mounted. Can be overridden at the pod level.

- **imagePullSecrets** ([\[\]LocalObjectReference](#))

ImagePullSecrets is a list of references to secrets in the same namespace to use for pulling any images in pods that reference this ServiceAccount. ImagePullSecrets are distinct from Secrets because Secrets can be mounted in the pod, but ImagePullSecrets are only accessed by the kubelet. More info: <https://kubernetes.io/docs/concepts/containers/images/#specifying-imagepullsecrets-on-a-pod>

- **secrets** ([\[\]ObjectReference](#))

*Patch strategy: merge on key name*

Secrets is a list of the secrets in the same namespace that pods running using this ServiceAccount are allowed to use. Pods are only limited to this list if this service account has a "kubernetes.io/enforce-mountable-secrets" annotation set to "true". This field should not be used to find auto-generated service account token secrets for use outside of pods. Instead, tokens can be requested directly using the TokenRequest API, or service account token secrets can be manually created. More info: <https://kubernetes.io/docs/concepts/configuration/secret>

## ServiceAccountList

ServiceAccountList is a list of ServiceAccount objects

---

- **apiVersion:** v1
- **kind:** ServiceAccountList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]ServiceAccount](#)), required

List of ServiceAccounts. More info: <https://kubernetes.io/docs/tasks/configure-pod-container/configure-service-account/>

## Operations

---

# TokenRequest

TokenRequest requests a token for a given service account.

apiVersion: authentication.k8s.io/v1

import "k8s.io/api/authentication/v1"

## TokenRequest

TokenRequest requests a token for a given service account.

- 
- **apiVersion**: authentication.k8s.io/v1
  - **kind**: TokenRequest
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([TokenRequestSpec](#)), required

Spec holds information about the request being evaluated

- **status** ([TokenRequestStatus](#))

Status is filled in by the server and indicates whether the token can be authenticated.

# TokenRequestSpec

TokenRequestSpec contains client provided parameters of a token request.

---

- **audiences** ([]string), required

Audiences are the intended audiences of the token. A recipient of a token must identify itself with an identifier in the list of audiences of the token, and otherwise should reject the token. A token issued for multiple audiences may be used to authenticate against any of the audiences listed but implies a high degree of trust between the target audiences.

- **boundObjectRef** (BoundObjectReference)

BoundObjectRef is a reference to an object that the token will be bound to. The token will only be valid for as long as the bound object exists. NOTE: The API server's TokenReview endpoint will validate the BoundObjectRef, but other audiences may not. Keep ExpirationSeconds small if you want prompt revocation.

*BoundObjectReference is a reference to an object that a token is bound to.*

- **boundObjectRef.apiVersion** (string)

API version of the referent.

- **boundObjectRef.kind** (string)

Kind of the referent. Valid kinds are 'Pod' and 'Secret'.

- **boundObjectRef.name** (string)

Name of the referent.

- **boundObjectRef.uid** (string)

UID of the referent.

- **expirationSeconds** (int64)

ExpirationSeconds is the requested duration of validity of the request. The token issuer may return a token with a different validity duration so a client needs to check the 'expiration' field in a response.

# TokenRequestStatus

TokenRequestStatus is the result of a token request.

---

- **expirationTimestamp** (Time), required

ExpirationTimestamp is the time of expiration of the returned token.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **token** (string), required

Token is the opaque bearer token.

## Operations

---

### create create token of a ServiceAccount

#### HTTP Request

POST /api/v1/namespaces/{namespace}/serviceaccounts/{name}/token

#### Parameters

- **name** (*in path*): string, required  
name of the TokenRequest
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [TokenRequest](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([TokenRequest](#)): OK

201 ([TokenRequest](#)): Created

202 ([TokenRequest](#)): Accepted

401: Unauthorized

# TokenReview

TokenReview attempts to authenticate a token to a known user.

apiVersion: authentication.k8s.io/v1

```
import "k8s.io/api/authentication/v1"
```

## TokenReview

TokenReview attempts to authenticate a token to a known user. Note: TokenReview requests may be cached by the webhook token authenticator plugin in the kube-apiserver.

---

- **apiVersion:** authentication.k8s.io/v1

- **kind:** TokenReview

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([TokenReviewSpec](#)), required

Spec holds information about the request being evaluated

- **status** ([TokenReviewStatus](#))

Status is filled in by the server and indicates whether the request can be authenticated.

## TokenReviewSpec

TokenReviewSpec is a description of the token authentication request.

---

- **audiences** ([]string)

Audiences is a list of the identifiers that the resource server presented with the token identifies as. Audience-aware token authenticators will verify that the token was intended for at least one of the audiences in this list. If no audiences are provided, the audience will default to the audience of the Kubernetes apiserver.

- **token** (string)

Token is the opaque bearer token.

## TokenReviewStatus

TokenReviewStatus is the result of the token authentication request.

---

- **audiences** ([]string)

Audiences are audience identifiers chosen by the authenticator that are compatible with both the TokenReview and token. An identifier is any identifier in the intersection of the TokenReviewSpec audiences and the token's audiences. A client of the TokenReview API that sets the spec.audiences field should validate that a compatible audience identifier is returned in the status.audiences field to ensure that the TokenReview server is audience aware. If a TokenReview returns an empty status.audience field where status.authenticated is "true", the token is valid against the audience of the Kubernetes API server.

- **authenticated** (boolean)

Authenticated indicates that the token was associated with a known user.

- **error** (string)

Error indicates that the token couldn't be checked

- **user** (UserInfo)

User is the UserInfo associated with the provided token.

*UserInfo holds the information about the user needed to implement the user.Info interface.*

- **user.extra** (map[string][]string)

Any additional information provided by the authenticator.

- **user.groups** ([]string)

The names of groups this user is a part of.

- **user.uid** (string)

A unique value that identifies this user across time. If this user is deleted and another user by the same name is added, they will have different UIDs.

- **user.username** (string)

The name that uniquely identifies this user among all active users.

## Operations

---

### create create a TokenReview

#### HTTP Request

POST /apis/authentication.k8s.io/v1/tokenreviews

## Parameters

- **body**: [TokenReview](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([TokenReview](#)): OK

201 ([TokenReview](#)): Created

202 ([TokenReview](#)): Accepted

401: Unauthorized

# CertificateSigningRequest

CertificateSigningRequest objects provide a mechanism to obtain x509 certificates by submitting a certificate signing request, and having it asynchronously approved and issued.

apiVersion: certificates.k8s.io/v1

import "k8s.io/api/certificates/v1"

## CertificateSigningRequest

CertificateSigningRequest objects provide a mechanism to obtain x509 certificates by submitting a certificate signing request, and having it asynchronously approved and issued.

Kubelets use this API to obtain:

1. client certificates to authenticate to kube-apiserver (with the "kubernetes.io/kube-apiserver-client-kubelet" signerName).
2. serving certificates for TLS endpoints kube-apiserver can connect to securely (with the "kubernetes.io/kubelet-serving" signerName).

This API can be used to request client certificates to authenticate to kube-apiserver (with the "kubernetes.io/kube-apiserver-client" signerName), or to obtain certificates from custom non-Kubernetes signers.

---

- **apiVersion:** certificates.k8s.io/v1
- **kind:** CertificateSigningRequest
- **metadata** ([ObjectMeta](#))
- **spec** ([CertificateSigningRequestSpec](#)), required

spec contains the certificate request, and is immutable after creation. Only the request, signerName, expirationSeconds, and usages fields can be set on creation. Other fields are derived by Kubernetes and cannot be modified by users.

- **status** ([CertificateSigningRequestStatus](#))

status contains information about whether the request is approved or denied, and the certificate issued by the signer, or the failure condition indicating signer failure.

## CertificateSigningRequestSpec

CertificateSigningRequestSpec contains the certificate request.

---

- **request** ([]byte), required

*Atomic: will be replaced during a merge*

request contains an x509 certificate signing request encoded in a "CERTIFICATE REQUEST" PEM block. When serialized as JSON or YAML, the data is additionally base64-encoded.

- **signerName** (string), required

signerName indicates the requested signer, and is a qualified name.

List/watch requests for CertificateSigningRequests can filter on this field using a "spec.signerName=NAME" fieldSelector.

Well-known Kubernetes signers are:

1. "kubernetes.io/kube-apiserver-client": issues client certificates that can be used to authenticate to kube-apiserver. Requests for this signer are never auto-approved by kube-controller-manager, can be issued by the "csrsigning" controller in kube-controller-manager.
2. "kubernetes.io/kube-apiserver-client-kubelet": issues client certificates that kubelets use to authenticate to kube-apiserver. Requests for this signer can be auto-approved by the "csrapproving" controller in kube-controller-manager, and can be issued by the "csrsigning" controller in kube-controller-manager.
3. "kubernetes.io/kubelet-serving" issues serving certificates that kubelets use to serve TLS endpoints, which kube-apiserver can connect to securely. Requests for this

signer are never auto-approved by kube-controller-manager, and can be issued by the "csrsigning" controller in kube-controller-manager.

More details are available at <https://k8s.io/docs/reference/access-authn-authz/certificate-signing-requests/#kubernetes-signers>

Custom signerNames can also be specified. The signer defines:

1. Trust distribution: how trust (CA bundles) are distributed.
2. Permitted subjects: and behavior when a disallowed subject is requested.
3. Required, permitted, or forbidden x509 extensions in the request (including whether subjectAltNames are allowed, which types, restrictions on allowed values) and behavior when a disallowed extension is requested.
4. Required, permitted, or forbidden key usages / extended key usages.
5. Expiration/certificate lifetime: whether it is fixed by the signer, configurable by the admin.
6. Whether or not requests for CA certificates are allowed.

- **expirationSeconds** (int32)

expirationSeconds is the requested duration of validity of the issued certificate. The certificate signer may issue a certificate with a different validity duration so a client must check the delta between the notBefore and notAfter fields in the issued certificate to determine the actual duration.

The v1.22+ in-tree implementations of the well-known Kubernetes signers will honor this field as long as the requested duration is not greater than the maximum duration they will honor per the --cluster-signing-duration CLI flag to the Kubernetes controller manager.

Certificate signers may not honor this field for various reasons:

1. Old signer that is unaware of the field (such as the in-tree implementations prior to v1.22)
2. Signer whose configured maximum is shorter than the requested duration
3. Signer whose configured minimum is longer than the requested duration

The minimum valid value for expirationSeconds is 600, i.e. 10 minutes.

- **extra** (map[string]string)

extra contains extra attributes of the user that created the CertificateSigningRequest. Populated by the API server on creation and immutable.

- **groups** ([]string)

*Atomic: will be replaced during a merge*

groups contains group membership of the user that created the CertificateSigningRequest. Populated by the API server on creation and immutable.

- **uid** (string)

uid contains the uid of the user that created the CertificateSigningRequest. Populated by the API server on creation and immutable.

• **usages** ([]string)

*Atomic: will be replaced during a merge*

usages specifies a set of key usages requested in the issued certificate.

Requests for TLS client certificates typically request: "digital signature", "key encipherment", "client auth".

Requests for TLS serving certificates typically request: "key encipherment", "digital signature", "server auth".

Valid values are: "signing", "digital signature", "content commitment", "key encipherment", "key agreement", "data encipherment", "cert sign", "crl sign", "encipher only", "decipher only", "any", "server auth", "client auth", "code signing", "email protection", "s/mime", "ipsec end system", "ipsec tunnel", "ipsec user", "timestamping", "ocsp signing", "microsoft sgc", "netscape sgc"

• **username** (string)

username contains the name of the user that created the CertificateSigningRequest. Populated by the API server on creation and immutable.

## CertificateSigningRequestStatus

CertificateSigningRequestStatus contains conditions used to indicate approved/denied/failed status of the request, and the issued certificate.

---

• **certificate** ([]byte)

*Atomic: will be replaced during a merge*

certificate is populated with an issued certificate by the signer after an Approved condition is present. This field is set via the /status subresource. Once populated, this field is immutable.

If the certificate signing request is denied, a condition of type "Denied" is added and this field remains empty. If the signer cannot issue the certificate, a condition of type "Failed" is added and this field remains empty.

Validation requirements:

1. certificate must contain one or more PEM blocks.
2. All PEM blocks must have the "CERTIFICATE" label, contain no headers, and the encoded data must be a BER-encoded ASN.1 Certificate structure as described in section 4 of RFC5280.
3. Non-PEM content may appear before or after the "CERTIFICATE" PEM blocks and is unvalidated, to allow for explanatory text as described in section 5.2 of RFC7468.

If more than one PEM block is present, and the definition of the requested spec.signerName does not indicate otherwise, the first block is the issued certificate, and subsequent blocks should be treated as intermediate certificates and presented in TLS handshakes.

The certificate is encoded in PEM format.

When serialized as JSON or YAML, the data is additionally base64-encoded, so it consists of:

```
base64(
-----BEGIN CERTIFICATE-----
...
-----END CERTIFICATE-----
)
```

- **conditions** ([]CertificateSigningRequestCondition)

*Map: unique values on key type will be kept during a merge*

conditions applied to the request. Known conditions are "Approved", "Denied", and "Failed".

*CertificateSigningRequestCondition describes a condition of a CertificateSigningRequest object*

- **conditions.status** (string), required

status of the condition, one of True, False, Unknown. Approved, Denied, and Failed conditions may not be "False" or "Unknown".

- **conditions.type** (string), required

type of the condition. Known conditions are "Approved", "Denied", and "Failed".

An "Approved" condition is added via the /approval subresource, indicating the request was approved and should be issued by the signer.

A "Denied" condition is added via the /approval subresource, indicating the request was denied and should not be issued by the signer.

A "Failed" condition is added via the /status subresource, indicating the signer failed to issue the certificate.

Approved and Denied conditions are mutually exclusive. Approved, Denied, and Failed conditions cannot be removed once added.

Only one condition of a given type is allowed.

- **conditions.lastTransitionTime** (Time)

lastTransitionTime is the time the condition last transitioned from one status to another. If unset, when a new condition type is added or an existing condition's status is changed, the server defaults this to the current time.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.lastUpdateTime** (Time)

lastUpdateTime is the time of the last update to this condition

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

message contains a human readable message with details about the request state

- **conditions.reason** (string)

reason indicates a brief reason for the request state

## CertificateSigningRequestList

CertificateSigningRequestList is a collection of CertificateSigningRequest objects

---

- **apiVersion:** certificates.k8s.io/v1
- **kind:** CertificateSigningRequestList
- **metadata** ([ListMeta](#))
- **items** ([][CertificateSigningRequest](#)), required

items is a collection of CertificateSigningRequest objects

## Operations

---

### get read the specified CertificateSigningRequest

#### HTTP Request

GET /apis/certificates.k8s.io/v1/certificatesigningrequests/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the CertificateSigningRequest
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([CertificateSigningRequest](#)): OK

# ClusterTrustBundle v1alpha1

ClusterTrustBundle is a cluster-scoped container for X.

apiVersion: certificates.k8s.io/v1alpha1

```
import "k8s.io/api/certificates/v1alpha1"
```

## ClusterTrustBundle

ClusterTrustBundle is a cluster-scoped container for X.509 trust anchors (root certificates).

ClusterTrustBundle objects are considered to be readable by any authenticated user in the cluster, because they can be mounted by pods using the clusterTrustBundle projection. All service accounts have read access to ClusterTrustBundles by default. Users who only have namespace-level access to a cluster can read ClusterTrustBundles by impersonating a serviceaccount that they have access to.

It can be optionally associated with a particular assigner, in which case it contains one valid set of trust anchors for that signer. Signers may have multiple associated ClusterTrustBundles; each is an independent set of trust anchors for that signer. Admission control is used to enforce that only users with permissions on the signer can create or modify the corresponding bundle.

---

- **apiVersion:** certificates.k8s.io/v1alpha1

- **kind:** ClusterTrustBundle

- **metadata** ([ObjectMeta](#))

metadata contains the object metadata.

- **spec** ([ClusterTrustBundleSpec](#)), required

spec contains the signer (if any) and trust anchors.

## ClusterTrustBundleSpec

ClusterTrustBundleSpec contains the signer and trust anchors.

---

- **trustBundle** (string), required

trustBundle contains the individual X.509 trust anchors for this bundle, as PEM bundle of PEM-wrapped, DER-formatted X.509 certificates.

The data must consist only of PEM certificate blocks that parse as valid X.509 certificates. Each certificate must include a basic constraints extension with the CA bit set. The API server will reject objects that contain duplicate certificates, or that use PEM block headers.

Users of ClusterTrustBundles, including Kubelet, are free to reorder and deduplicate certificate blocks in this file according to their own logic, as well as to drop PEM block headers and inter-block data.

- **signerName** (string)

signerName indicates the associated signer, if any.

In order to create or update a ClusterTrustBundle that sets signerName, you must have the following cluster-scoped permission: group=certificates.k8s.io resource=signers resourceName=<the signer name> verb=attest.

If signerName is not empty, then the ClusterTrustBundle object must be named with the signer name as a prefix (translating slashes to colons). For example, for the signer name example.com/foo, valid ClusterTrustBundle object names include example.com:foo:abc and example.com:foo:v1.

If signerName is empty, then the ClusterTrustBundle object's name must not have such a prefix.

List/watch requests for ClusterTrustBundles can filter on this field using a spec.signerName=NAME field selector.

## ClusterTrustBundleList

ClusterTrustBundleList is a collection of ClusterTrustBundle objects

---

- **apiVersion**: certificates.k8s.io/v1alpha1
- **kind**: ClusterTrustBundleList
- **metadata** ([ListMeta](#))

metadata contains the list metadata.

- **items** ([\[\]ClusterTrustBundle](#)), required

items is a collection of ClusterTrustBundle objects

## Operations

---

### get read the specified ClusterTrustBundle

#### HTTP Request

GET /apis/certificates.k8s.io/v1alpha1/clustertrustbundles/{name}

# SelfSubjectReview

SelfSubjectReview contains the user information that the kube-apiserver has about the user making this request.

apiVersion: authentication.k8s.io/v1

```
import "k8s.io/api/authentication/v1"
```

## SelfSubjectReview

SelfSubjectReview contains the user information that the kube-apiserver has about the user making this request. When using impersonation, users will receive the user info of the user being impersonated. If impersonation or request header authentication is used, any extra keys will have their case ignored and returned as lowercase.

- 
- **apiVersion**: authentication.k8s.io/v1
  - **kind**: SelfSubjectReview
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **status** ([SelfSubjectReviewStatus](#))

Status is filled in by the server with the user attributes.

# SelfSubjectReviewStatus

SelfSubjectReviewStatus is filled by the kube-apiserver and sent back to a user.

---

- **userInfo** (UserInfo)

User attributes of the user making this request.

*UserInfo holds the information about the user needed to implement the user.Info interface.*

- **userInfo.extra** (map[string][]string)

Any additional information provided by the authenticator.

- **userInfo.groups** ([]string)

The names of groups this user is a part of.

- **userInfo.uid** (string)

A unique value that identifies this user across time. If this user is deleted and another user by the same name is added, they will have different UIDs.

- **userInfo.username** (string)

The name that uniquely identifies this user among all active users.

## Operations

---

### create create a SelfSubjectReview

#### HTTP Request

POST /apis/authentication.k8s.io/v1/selfsubjectreviews

#### Parameters

- **body**: [SelfSubjectReview](#), required

- **dryRun** (*in query*): string

[dryRun](#)

- **fieldManager** (*in query*): string

[fieldManager](#)

- **fieldValidation** (*in query*): string

# Authorization Resources

---

## [LocalSubjectAccessReview](#)

LocalSubjectAccessReview checks whether or not a user or group can perform an action in a given namespace.

## [SelfSubjectAccessReview](#)

SelfSubjectAccessReview checks whether or the current user can perform an action.

## [SelfSubjectRulesReview](#)

SelfSubjectRulesReview enumerates the set of actions the current user can perform within a namespace.

## [SubjectAccessReview](#)

SubjectAccessReview checks whether or not a user or group can perform an action.

## [ClusterRole](#)

ClusterRole is a cluster level, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding or ClusterRoleBinding.

## [ClusterRoleBinding](#)

ClusterRoleBinding references a ClusterRole, but not contain it.

## [Role](#)

Role is a namespaced, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding.

## [RoleBinding](#)

RoleBinding references a role, but does not contain it.

# LocalSubjectAccessReview

LocalSubjectAccessReview checks whether or not a user or group can perform an action in a given namespace.

apiVersion: authorization.k8s.io/v1

import "k8s.io/api/authorization/v1"

## LocalSubjectAccessReview

LocalSubjectAccessReview checks whether or not a user or group can perform an action in a given namespace. Having a namespace scoped resource makes it much easier to grant namespace scoped policy that includes permissions checking.

---

- **apiVersion:** authorization.k8s.io/v1

- **kind:** LocalSubjectAccessReview

- **metadata** ([ObjectMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([SubjectAccessReviewSpec](#)), required

Spec holds information about the request being evaluated. spec.namespace must be equal to the namespace you made the request against. If empty, it is defaulted.

- **status** ([SubjectAccessReviewStatus](#))

Status is filled in by the server and indicates whether the request is allowed or not

## Operations

---

### create create a LocalSubjectAccessReview

#### HTTP Request

POST /apis/authorization.k8s.io/v1/namespaces/{namespace}/localsubjectaccessreviews

#### Parameters

- **namespace** (*in path*): string, required

[namespace](#)

- **body**: [LocalSubjectAccessReview](#), required
- **dryRun** (*in query*): string

[dryRun](#)

- **fieldManager** (*in query*): string

[fieldManager](#)

- **fieldValidation** (*in query*): string

201 ([LocalSubjectAccessReview](#)): Created

202 ([LocalSubjectAccessReview](#)): Accepted

401: Unauthorized

# SelfSubjectAccessReview

SelfSubjectAccessReview checks whether or the current user can perform an action.

apiVersion: authorization.k8s.io/v1

import "k8s.io/api/authorization/v1"

## SelfSubjectAccessReview

SelfSubjectAccessReview checks whether or the current user can perform an action. Not filling in a spec.namespace means "in all namespaces". Self is a special case, because users should always be able to check whether they can perform an action

- 
- **apiVersion**: authorization.k8s.io/v1
  - **kind**: SelfSubjectAccessReview
  - **metadata** ([ObjectMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([SelfSubjectAccessReviewSpec](#)), required
  - Spec holds information about the request being evaluated. user and groups must be empty
- **status** ([SubjectAccessReviewStatus](#))
  - Status is filled in by the server and indicates whether the request is allowed or not

## SelfSubjectAccessReviewSpec

SelfSubjectAccessReviewSpec is a description of the access request. Exactly one of ResourceAuthorizationAttributes and NonResourceAuthorizationAttributes must be set

---

- **nonResourceAttributes** (NonResourceAttributes)

NonResourceAttributes describes information for a non-resource access request

*NonResourceAttributes includes the authorization attributes available for non-resource requests to the Authorizer interface*

- **nonResourceAttributes.path** (string)

Path is the URL path of the request

- **nonResourceAttributes.verb** (string)

Verb is the standard HTTP verb

- **resourceAttributes** (ResourceAttributes)

ResourceAuthorizationAttributes describes information for a resource access request

*ResourceAttributes includes the authorization attributes available for resource requests to the Authorizer interface*

- **resourceAttributes.group** (string)

Group is the API Group of the Resource. "\*" means all.

- **resourceAttributes.name** (string)

Name is the name of the resource being requested for a "get" or deleted for a "delete". "" (empty) means all.

- **resourceAttributes.namespace** (string)

Namespace is the namespace of the action being requested. Currently, there is no distinction between no namespace and all namespaces "" (empty) is defaulted for LocalSubjectAccessReviews "" (empty) is empty for cluster-scoped resources "" (empty) means "all" for namespace scoped resources from a SubjectAccessReview or SelfSubjectAccessReview

- **resourceAttributes.resource** (string)

Resource is one of the existing resource types. "\*" means all.

- **resourceAttributes.subresource** (string)

Subresource is one of the existing resource types. "" means none.

- **resourceAttributes.verb** (string)

Verb is a kubernetes resource API verb, like: get, list, watch, create, update, delete, proxy. "\*" means all.

- **resourceAttributes.version** (string)

Version is the API Version of the Resource. "\*" means all.

## Operations

# SelfSubjectRulesReview

SelfSubjectRulesReview enumerates the set of actions the current user can perform within a namespace.

apiVersion: authorization.k8s.io/v1

import "k8s.io/api/authorization/v1"

## SelfSubjectRulesReview

SelfSubjectRulesReview enumerates the set of actions the current user can perform within a namespace. The returned list of actions may be incomplete depending on the server's authorization mode, and any errors experienced during the evaluation. SelfSubjectRulesReview should be used by UIs to show/hide actions, or to quickly let an end user reason about their permissions. It should NOT Be used by external systems to drive authorization decisions as this raises confused deputy, cache lifetime/revocation, and correctness concerns.

SubjectAccessReview, and LocalAccessReview are the correct way to defer authorization decisions to the API server.

---

- **apiVersion:** authorization.k8s.io/v1

- **kind:** SelfSubjectRulesReview

- **metadata** ([ObjectMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([SelfSubjectRulesReviewSpec](#)), required

Spec holds information about the request being evaluated.

- **status** (SubjectRulesReviewStatus)

Status is filled in by the server and indicates the set of actions a user can perform.

*SubjectRulesReviewStatus contains the result of a rules check. This check can be incomplete depending on the set of authorizers the server is configured with and any errors experienced during evaluation. Because authorization rules are additive, if a rule appears in a list it's safe to assume the subject has that permission, even if that list is incomplete.*

- **status.incomplete** (boolean), required

Incomplete is true when the rules returned by this call are incomplete. This is most commonly encountered when an authorizer, such as an external authorizer, doesn't support rules evaluation.

- **status.nonResourceRules** ([]NonResourceRule), required

NonResourceRules is the list of actions the subject is allowed to perform on non-resources. The list ordering isn't significant, may contain duplicates, and possibly be incomplete.

*NonResourceRule holds information that describes a rule for the non-resource*

- **status.nonResourceRules.verbs** ([]string), required

Verb is a list of kubernetes non-resource API verbs, like: get, post, put, delete, patch, head, options. "\*" means all.

- **status.nonResourceRules.nonResourceURLs** ([]string)

NonResourceURLs is a set of partial urls that a user should have access to. s are allowed, but only as the full, final step in the path. "" means all.

- **status.resourceRules** ([]ResourceRule), required

ResourceRules is the list of actions the subject is allowed to perform on resources. The list ordering isn't significant, may contain duplicates, and possibly be incomplete.

*ResourceRule is the list of actions the subject is allowed to perform on resources. The list ordering isn't significant, may contain duplicates, and possibly be incomplete.*

- **status.resourceRules.verbs** ([]string), required

Verb is a list of kubernetes resource API verbs, like: get, list, watch, create, update, delete, proxy. "\*" means all.

- **status.resourceRules.apiGroups** ([]string)

APIGroups is the name of the APIGroup that contains the resources. If multiple API groups are specified, any action requested against one of the enumerated resources in any API group will be allowed. "\*" means all.

- **status.resourceRules.resourceNames** ([]string)

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed. "\*" means all.

- **status.resourceRules.resources** ([]string)

Resources is a list of resources this rule applies to. "" means all in the specified apiGroups. "/foo" represents the subresource 'foo' for all resources in the specified apiGroups.

- **status.evaluationError** (string)

EvaluationError can appear in combination with Rules. It indicates an error occurred during rule evaluation, such as an authorizer that doesn't support rule evaluation, and that ResourceRules and/or NonResourceRules may be incomplete.

# SelfSubjectRulesReviewSpec

SelfSubjectRulesReviewSpec defines the specification for SelfSubjectRulesReview.

---

- **namespace** (string)

Namespace to evaluate rules for. Required.

## Operations

---

### create create a SelfSubjectRulesReview

#### HTTP Request

POST /apis/authorization.k8s.io/v1/selfsubjectrulesreviews

#### Parameters

- **body**: [SelfSubjectRulesReview](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([SelfSubjectRulesReview](#)): OK

201 ([SelfSubjectRulesReview](#)): Created

202 ([SelfSubjectRulesReview](#)): Accepted

401: Unauthorized

# SubjectAccessReview

SubjectAccessReview checks whether or not a user or group can perform an action.

apiVersion: authorization.k8s.io/v1

import "k8s.io/api/authorization/v1"

## SubjectAccessReview

SubjectAccessReview checks whether or not a user or group can perform an action.

---

- **apiVersion:** authorization.k8s.io/v1

- **kind:** SubjectAccessReview

- **metadata** ([ObjectMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([SubjectAccessReviewSpec](#)), required

Spec holds information about the request being evaluated

- **status** ([SubjectAccessReviewStatus](#))

Status is filled in by the server and indicates whether the request is allowed or not

## SubjectAccessReviewSpec

SubjectAccessReviewSpec is a description of the access request. Exactly one of ResourceAuthorizationAttributes and NonResourceAuthorizationAttributes must be set

---

- **extra** (map[string][]string)

Extra corresponds to the user.Info.GetExtra() method from the authenticator. Since that is input to the authorizer it needs a reflection here.

- **groups** ([]string)

Groups is the groups you're testing for.

- **nonResourceAttributes** (NonResourceAttributes)

NonResourceAttributes describes information for a non-resource access request

*NonResourceAttributes includes the authorization attributes available for non-resource requests to the Authorizer interface*

- **nonResourceAttributes.path** (string)

Path is the URL path of the request

- **nonResourceAttributes.verb** (string)

Verb is the standard HTTP verb

- **resourceAttributes** (ResourceAttributes)

ResourceAuthorizationAttributes describes information for a resource access request

*ResourceAttributes includes the authorization attributes available for resource requests to the Authorizer interface*

- **resourceAttributes.group** (string)

Group is the API Group of the Resource. "\*" means all.

- **resourceAttributes.name** (string)

Name is the name of the resource being requested for a "get" or deleted for a "delete". "" (empty) means all.

- **resourceAttributes.namespace** (string)

Namespace is the namespace of the action being requested. Currently, there is no distinction between no namespace and all namespaces "" (empty) is defaulted for LocalSubjectAccessReviews "" (empty) is empty for cluster-scoped resources "" (empty) means "all" for namespace scoped resources from a SubjectAccessReview or SelfSubjectAccessReview

- **resourceAttributes.resource** (string)

Resource is one of the existing resource types. "\*" means all.

- **resourceAttributes.subresource** (string)

Subresource is one of the existing resource types. "" means none.

- **resourceAttributes.verb** (string)

Verb is a kubernetes resource API verb, like: get, list, watch, create, update, delete, proxy. "\*" means all.

- **resourceAttributes.version** (string)

Version is the API Version of the Resource. "\*" means all.

- **uid** (string)

UID information about the requesting user.

- **user** (string)

User is the user you're testing for. If you specify "User" but not "Groups", then is it interpreted as "What if User were not a member of any groups"

# SubjectAccessReviewStatus

SubjectAccessReviewStatus

---

- **allowed** (boolean), required

Allowed is required. True if the action would be allowed, false otherwise.

- **denied** (boolean)

Denied is optional. True if the action would be denied, otherwise false. If both allowed is false and denied is false, then the authorizer has no opinion on whether to authorize the action. Denied may not be true if Allowed is true.

- **evaluationError** (string)

EvaluationError is an indication that some error occurred during the authorization check. It is entirely possible to get an error and be able to continue determine authorization status in spite of it. For instance, RBAC can be missing a role, but enough roles are still present and bound to reason about the request.

- **reason** (string)

Reason is optional. It indicates why a request was allowed or denied.

## Operations

---

### create create a SubjectAccessReview

#### HTTP Request

POST /apis/authorization.k8s.io/v1/subjectaccessreviews

#### Parameters

- **body**: [SubjectAccessReview](#), required

- **dryRun** (*in query*): string

[dryRun](#)

- **fieldManager** (*in query*): string

[fieldManager](#)

- **fieldValidation** (*in query*): string

[fieldValidation](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([SubjectAccessReview](#)): OK

201 ([SubjectAccessReview](#)): Created

202 ([SubjectAccessReview](#)): Accepted

401: Unauthorized

# ClusterRole

ClusterRole is a cluster level, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding or ClusterRoleBinding.

apiVersion: rbac.authorization.k8s.io/v1

```
import "k8s.io/api/rbac/v1"
```

## ClusterRole

ClusterRole is a cluster level, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding or ClusterRoleBinding.

---

- **apiVersion:** rbac.authorization.k8s.io/v1

- **kind:** ClusterRole

- **metadata** ([ObjectMeta](#))

Standard object's metadata.

- **aggregationRule** (AggregationRule)

AggregationRule is an optional field that describes how to build the Rules for this ClusterRole. If AggregationRule is set, then the Rules are controller managed and direct changes to Rules will be stomped by the controller.

*AggregationRule describes how to locate ClusterRoles to aggregate into the ClusterRole*

- **aggregationRule.clusterRoleSelectors** ([][LabelSelector](#))

ClusterRoleSelectors holds a list of selectors which will be used to find ClusterRoles and create the rules. If any of the selectors match, then the ClusterRole's permissions will be added

- **rules** ([]PolicyRule)

Rules holds all the PolicyRules for this ClusterRole

*PolicyRule holds information that describes a policy rule, but does not contain information about who the rule applies to or which namespace the rule applies to.*

- **rules.apiGroups** ([]string)

APIGroups is the name of the APIGroup that contains the resources. If multiple API groups are specified, any action requested against one of the enumerated resources in any API group will be allowed. "" represents the core API group and "\*" represents all API groups.

- **rules.resources** ([]string)

Resources is a list of resources this rule applies to. "\*" represents all resources.

- **rules.verbs** ([]string), required

Verbs is a list of Verbs that apply to ALL the ResourceKinds contained in this rule. "\*" represents all verbs.

- **rules.resourceNames** ([]string)

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

- **rules.nonResourceURLs** ([]string)

NonResourceURLs is a set of partial urls that a user should have access to. \*s are allowed, but only as the full, final step in the path Since non-resource URLs are not namespaced, this field is only applicable for ClusterRoles referenced from a ClusterRoleBinding. Rules can either apply to API resources (such as "pods" or "secrets") or non-resource URL paths (such as "/api"), but not both.

## ClusterRoleList

ClusterRoleList is a collection of ClusterRoles

---

- **apiVersion:** rbac.authorization.k8s.io/v1

- **kind:** ClusterRoleList

- **metadata** ([ListMeta](#))

Standard object's metadata.

- **items** ([][ClusterRole](#)), required

Items is a list of ClusterRoles

## Operations

---

## get read the specified ClusterRole

### HTTP Request

GET /apis/rbac.authorization.k8s.io/v1/clusterroles/{name}

### Parameters

# ClusterRoleBinding

ClusterRoleBinding references a ClusterRole, but not contain it.

apiVersion: rbac.authorization.k8s.io/v1

```
import "k8s.io/api/rbac/v1"
```

## ClusterRoleBinding

ClusterRoleBinding references a ClusterRole, but not contain it. It can reference a ClusterRole in the global namespace, and adds who information via Subject.

- 
- **apiVersion**: rbac.authorization.k8s.io/v1
  - **kind**: ClusterRoleBinding
  - **metadata** ([ObjectMeta](#))  
Standard object's metadata.
  - **roleRef** (RoleRef), required

RoleRef can only reference a ClusterRole in the global namespace. If the RoleRef cannot be resolved, the Authorizer must return an error. This field is immutable.

*RoleRef contains information that points to the role being used*

- **roleRef.apiGroup** (string), required

APIGroup is the group for the resource being referenced

- **roleRef.kind** (string), required

Kind is the type of resource being referenced

- **roleRef.name** (string), required

Name is the name of resource being referenced

- **subjects** ([]Subject)

Subjects holds references to the objects the role applies to.

*Subject contains a reference to the object or user identities a role binding applies to. This can either hold a direct API object reference, or a value for non-objects such as user and group names.*

- **subjects.kind** (string), required

Kind of object being referenced. Values defined by this API group are "User", "Group", and "ServiceAccount". If the Authorizer does not recognize the kind value, the Authorizer should report an error.

- **subjects.name** (string), required

Name of the object being referenced.

- **subjects.apiGroup** (string)

APIGroup holds the API group of the referenced subject. Defaults to "" for ServiceAccount subjects. Defaults to "rbac.authorization.k8s.io" for User and Group subjects.

- **subjects.namespace** (string)

Namespace of the referenced object. If the object kind is non-namespace, such as "User" or "Group", and this value is not empty the Authorizer should report an error.

## ClusterRoleBindingList

ClusterRoleBindingList is a collection of ClusterRoleBindings

- 
- **apiVersion:** rbac.authorization.k8s.io/v1
  - **kind:** ClusterRoleBindingList

- **metadata** ([ListMeta](#))
- Standard object's metadata.
- **items** ([\[\]ClusterRoleBinding](#)), required  
Items is a list of ClusterRoleBindings

## Operations

---

### get read the specified ClusterRoleBinding

# Role

Role is a namespaced, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding.

apiVersion: rbac.authorization.k8s.io/v1

```
import "k8s.io/api/rbac/v1"
```

## Role

Role is a namespaced, logical grouping of PolicyRules that can be referenced as a unit by a RoleBinding.

---

- **apiVersion:** rbac.authorization.k8s.io/v1

- **kind:** Role

- **metadata** ([ObjectMeta](#))

Standard object's metadata.

- **rules** ([]PolicyRule)

Rules holds all the PolicyRules for this Role

*PolicyRule holds information that describes a policy rule, but does not contain information about who the rule applies to or which namespace the rule applies to.*

- **rules.apiGroups** ([]string)

APIGroups is the name of the APIGroup that contains the resources. If multiple API groups are specified, any action requested against one of the enumerated resources in any API group will be allowed. "" represents the core API group and "\*" represents all API groups.

- **rules.resources** ([]string)

Resources is a list of resources this rule applies to. "\*" represents all resources.

- **rules.verbs** ([]string), required

Verbs is a list of Verbs that apply to ALL the ResourceKinds contained in this rule. "\*" represents all verbs.

- **rules.resourceNames** ([]string)

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

- **rules.nonResourceURLs** ([]string)

NonResourceURLs is a set of partial urls that a user should have access to. \*s are allowed, but only as the full, final step in the path Since non-resource URLs are not namespaced, this field is only applicable for ClusterRoles referenced from a ClusterRoleBinding. Rules can either apply to API resources (such as "pods" or "secrets") or non-resource URL paths (such as "/api"), but not both.

# RoleList

RoleList is a collection of Roles

---

# RoleBinding

RoleBinding references a role, but does not contain it.

apiVersion: rbac.authorization.k8s.io/v1

```
import "k8s.io/api/rbac/v1"
```

## RoleBinding

RoleBinding references a role, but does not contain it. It can reference a Role in the same namespace or a ClusterRole in the global namespace. It adds who information via Subjects and namespace information by which namespace it exists in. RoleBindings in a given namespace only have effect in that namespace.

- 
- **apiVersion**: rbac.authorization.k8s.io/v1
  - **kind**: RoleBinding
  - **metadata** ([ObjectMeta](#))

Standard object's metadata.

**roleRef** (RoleRef), required

- RoleRef can reference a Role in the current namespace or a ClusterRole in the global namespace. If the RoleRef cannot be resolved, the Authorizer must return an error. This field is immutable.

*RoleRef contains information that points to the role being used*

- **roleRef.apiGroup** (string), required

APIGroup is the group for the resource being referenced

- **roleRef.kind** (string), required

Kind is the type of resource being referenced

- **roleRef.name** (string), required

Name is the name of resource being referenced

- **subjects** ([]Subject)

Subjects holds references to the objects the role applies to.

*Subject contains a reference to the object or user identities a role binding applies to. This can either hold a direct API object reference, or a value for non-objects such as user and group names.*

- **subjects.kind** (string), required

Kind of object being referenced. Values defined by this API group are "User", "Group", and "ServiceAccount". If the Authorizer does not recognize the kind value, the Authorizer should report an error.

- **subjects.name** (string), required

Name of the object being referenced.

- **subjects.apiGroup** (string)

APIGroup holds the API group of the referenced subject. Defaults to "" for ServiceAccount subjects. Defaults to "rbac.authorization.k8s.io" for User and Group subjects.

- **subjects.namespace** (string)

Namespace of the referenced object. If the object kind is non-namespace, such as "User" or "Group", and this value is not empty the Authorizer should report an error.

## RoleBindingList

RoleBindingList is a collection of RoleBindings

- 
- **apiVersion:** rbac.authorization.k8s.io/v1
  - **kind:** RoleBindingList
  - **metadata** ([ListMeta](#))  
Standard object's metadata.
  - **items** ([\[\]RoleBinding](#)), required  
Items is a list of RoleBindings

## Operations

---

### get read the specified RoleBinding

#### HTTP Request

GET /apis/rbac.authorization.k8s.io/v1/namespaces/{namespace}/rolebindings/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the RoleBinding
- **namespace** (*in path*): string, required  
[namespace](#)
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([RoleBinding](#)): OK

401: Unauthorized

### list list or watch objects of kind RoleBinding

#### HTTP Request

# Policy Resources

---

## [LimitRange](#)

LimitRange sets resource usage limits for each kind of resource in a Namespace.

## [ResourceQuota](#)

ResourceQuota sets aggregate quota restrictions enforced per namespace.

## [NetworkPolicy](#)

NetworkPolicy describes what network traffic is allowed for a set of Pods.

## [PodDisruptionBudget](#)

PodDisruptionBudget is an object to define the max disruption that can be caused to a collection of pods.

## [IPAddress v1alpha1](#)

IPAddress represents a single IP of a single IP Family.

# LimitRange

LimitRange sets resource usage limits for each kind of resource in a Namespace.

apiVersion: v1

import "k8s.io/api/core/v1"

# LimitRange

LimitRange sets resource usage limits for each kind of resource in a Namespace.

---

- **apiVersion:** v1
- **kind:** LimitRange
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([LimitRangeSpec](#))

Spec defines the limits enforced. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

# LimitRangeSpec

LimitRangeSpec defines a min/max usage limit for resources that match on kind.

---

- **limits** ([]LimitRangeItem), required

Limits is the list of LimitRangeItem objects that are enforced.

*LimitRangeItem defines a min/max usage limit for any resource that matches on kind.*

- **limits.type** (string), required

Type of resource that this limit applies to.

- **limits.default** (map[string][Quantity](#))

Default resource requirement limit value by resource name if resource limit is omitted.

- **limits.defaultRequest** (map[string][Quantity](#))

DefaultRequest is the default resource requirement request value by resource name if resource request is omitted.

- **limits.max** (map[string][Quantity](#))

Max usage constraints on this kind by resource name.

- **limits.maxLimitRequestRatio** (map[string][Quantity](#))

MaxLimitRequestRatio if specified, the named resource must have a request and limit that are both non-zero where limit divided by request is less than or equal to the enumerated value; this represents the max burst for the named resource.

- **limits.min** (map[string][Quantity](#))

Min usage constraints on this kind by resource name.

## LimitRangeList

LimitRangeList is a list of LimitRange items.

- 
- **apiVersion:** v1
  - **kind:** LimitRangeList
  - **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([][LimitRange](#)), required

Items is a list of LimitRange objects. More info: <https://kubernetes.io/docs/concepts/configuration/manage-resources-containers/>

## Operations

---

# ResourceQuota

ResourceQuota sets aggregate quota restrictions enforced per namespace.

apiVersion: v1

import "k8s.io/api/core/v1"

## ResourceQuota

ResourceQuota sets aggregate quota restrictions enforced per namespace

---

- **apiVersion:** v1
- **kind:** ResourceQuota
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([ResourceQuotaSpec](#))

Spec defines the desired quota. <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([ResourceQuotaStatus](#))

Status defines the actual enforced quota and its current usage. <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## ResourceQuotaSpec

ResourceQuotaSpec defines the desired hard limits to enforce for Quota.

---

- **hard** (map[string][Quantity](#))

hard is the set of desired hard limits for each named resource. More info: <https://kubernetes.io/docs/concepts/policy/resource-quotas/>

- **scopeSelector** (ScopeSelector)

scopeSelector is also a collection of filters like scopes that must match each object tracked by a quota but expressed using ScopeSelectorOperator in combination with possible values. For a resource to match, both scopes AND scopeSelector (if specified in spec), must be matched.

*A scope selector represents the AND of the selectors represented by the scoped-resource selector requirements.*

- **scopeSelector.matchExpressions** ([]ScopedResourceSelectorRequirement)

A list of scope selector requirements by scope of the resources.

*A scoped-resource selector requirement is a selector that contains values, a scope name, and an operator that relates the scope name and values.*

- **scopeSelector.matchExpressions.operator** (string), required

Represents a scope's relationship to a set of values. Valid operators are In, NotIn, Exists, DoesNotExist.

- **scopeSelector.matchExpressions.scopeName** (string), required

The name of the scope that the selector applies to.

- **scopeSelector.matchExpressions.values** ([]string)

An array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **scopes** ([]string)

A collection of filters that must match each object tracked by a quota. If not specified, the quota matches all objects.

## ResourceQuotaStatus

ResourceQuotaStatus defines the enforced hard limits and observed use.

---

- **hard** (map[string][Quantity](#))

Hard is the set of enforced hard limits for each named resource. More info: <https://kubernetes.io/docs/concepts/policy/resource-quotas/>

- **used** (map[string][Quantity](#))

Used is the current observed total usage of the resource in the namespace.

## ResourceQuotaList

ResourceQuotaList is a list of ResourceQuota items.

---

- **apiVersion**: v1
- **kind**: ResourceQuotaList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([][ResourceQuota](#)), required

Items is a list of ResourceQuota objects. More info: <https://kubernetes.io/docs/concepts/policy/resource-quotas/>

## Operations

# NetworkPolicy

NetworkPolicy describes what network traffic is allowed for a set of Pods.

apiVersion: networking.k8s.io/v1

import "k8s.io/api/networking/v1"

## NetworkPolicy

NetworkPolicy describes what network traffic is allowed for a set of Pods

- 
- **apiVersion:** networking.k8s.io/v1
  - **kind:** NetworkPolicy
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([NetworkPolicySpec](#))

spec represents the specification of the desired behavior for this NetworkPolicy.

## NetworkPolicySpec

NetworkPolicySpec provides the specification of a NetworkPolicy

- 
- **podSelector** ([LabelSelector](#)), required

podSelector selects the pods to which this NetworkPolicy object applies. The array of ingress rules is applied to any pods selected by this field. Multiple network policies can select the same set of pods. In this case, the ingress rules for each are combined additively. This field is NOT optional and follows standard label selector semantics. An empty podSelector matches all pods in this namespace.

- **policyTypes** ([]string)

policyTypes is a list of rule types that the NetworkPolicy relates to. Valid options are ["Ingress"], ["Egress"], or ["Ingress", "Egress"]. If this field is not specified, it will default based on the existence of ingress or egress rules; policies that contain an egress section are assumed to affect egress, and all policies (whether or not they contain an ingress section) are assumed to affect ingress. If you want to write an egress-only policy, you must explicitly specify policyTypes [ "Egress" ]. Likewise, if you want to write a policy that specifies that no egress is allowed, you must specify a policyTypes value that include "Egress" (since such a policy would not include an egress section and would otherwise default to just [ "Ingress" ]). This field is beta-level in 1.8

- **ingress** ([]NetworkPolicyIngressRule)

ingress is a list of ingress rules to be applied to the selected pods. Traffic is allowed to a pod if there are no NetworkPolicies selecting the pod (and cluster policy otherwise allows the traffic), OR if the traffic source is the pod's local node, OR if the traffic matches at least one ingress rule across all of the NetworkPolicy objects whose podSelector matches the pod. If this field is empty then this NetworkPolicy does not allow any traffic (and serves solely to ensure that the pods it selects are isolated by default)

*NetworkPolicyIngressRule describes a particular set of traffic that is allowed to the pods matched by a NetworkPolicySpec's podSelector. The traffic must match both ports and from.*

- **ingress.from** ([]NetworkPolicyPeer)

from is a list of sources which should be able to access the pods selected for this rule. Items in this list are combined using a logical OR operation. If this field is empty or missing, this rule matches all sources (traffic not restricted by source). If this field is present and contains at least one item, this rule allows traffic only if the traffic matches at least one item in the from list.

*NetworkPolicyPeer describes a peer to allow traffic to/from. Only certain combinations of fields are allowed*

- **ingress.from.ipBlock** (IPBlock)

ipBlock defines policy on a particular IPBlock. If this field is set then neither of the other fields can be.

*IPBlock describes a particular CIDR (Ex. "192.168.1.0/24","2001:db8::/64") that is allowed to the pods matched by a NetworkPolicySpec's podSelector. The except entry describes CIDRs that should not be included within this rule.*

- **ingress.from.ipBlock.cidr** (string), required

cidr is a string representing the IPBlock Valid examples are "192.168.1.0/24" or "2001:db8::/64"

- **ingress.from.ipBlock.except** ([]string)

except is a slice of CIDRs that should not be included within an IPBlock Valid examples are "192.168.1.0/24" or "2001:db8::/64" Except values will be rejected if they are outside the cidr range

- **ingress.from.namespaceSelector** ([LabelSelector](#))

namespaceSelector selects namespaces using cluster-scoped labels. This field follows standard label selector semantics; if present but empty, it selects all namespaces.

If podSelector is also set, then the NetworkPolicyPeer as a whole selects the pods matching podSelector in the namespaces selected by namespaceSelector. Otherwise it selects all pods in the namespaces selected by namespaceSelector.

- **ingress.from.podSelector** ([LabelSelector](#))

podSelector is a label selector which selects pods. This field follows standard label selector semantics; if present but empty, it selects all pods.

If namespaceSelector is also set, then the NetworkPolicyPeer as a whole selects the pods matching podSelector in the Namespaces selected by NamespaceSelector. Otherwise it selects the pods matching podSelector in the policy's own namespace.

- **ingress.ports** ([]NetworkPolicyPort)

ports is a list of ports which should be made accessible on the pods selected for this rule. Each item in this list is combined using a logical OR. If this field is empty or missing, this rule matches all ports (traffic not restricted by port). If this field is present and contains at least one item, then this rule allows traffic only if the traffic matches at least one port in the list.

*NetworkPolicyPort describes a port to allow traffic on*

- **ingress.ports.port** (IntOrString)

port represents the port on the given protocol. This can either be a numerical or named port on a pod. If this field is not provided, this matches all port names and numbers. If present, only traffic on the specified protocol AND port will be matched.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **ingress.ports.endPort** (int32)

endPort indicates that the range of ports from port to endPort if set, inclusive, should be allowed by the policy. This field cannot be defined if the port field is not defined or if the port field is defined as a named (string) port. The endPort must be equal or greater than port.

- **ingress.ports.protocol** (string)

protocol represents the protocol (TCP, UDP, or SCTP) which traffic must match. If not specified, this field defaults to TCP.

- **egress** ([]NetworkPolicyEgressRule)

egress is a list of egress rules to be applied to the selected pods. Outgoing traffic is allowed if there are no NetworkPolicies selecting the pod (and cluster policy otherwise allows the traffic), OR if the traffic matches at least one egress rule across all of the NetworkPolicy objects whose podSelector matches the pod. If this field is empty then this NetworkPolicy limits all outgoing traffic (and serves solely to ensure that the pods it selects are isolated by default). This field is beta-level in 1.8

*NetworkPolicyEgressRule describes a particular set of traffic that is allowed out of pods matched by a NetworkPolicySpec's podSelector. The traffic must match both ports and to. This type is beta-level in 1.8*

- **egress.to** ([]NetworkPolicyPeer)

to is a list of destinations for outgoing traffic of pods selected for this rule. Items in this list are combined using a logical OR operation. If this field is empty or missing, this rule matches all destinations (traffic not restricted by destination). If this field is present and contains at least one item, this rule allows traffic only if the traffic matches at least one item in the to list.

*NetworkPolicyPeer describes a peer to allow traffic to/from. Only certain combinations of fields are allowed*

- **egress.to.ipBlock** (IPBlock)

ipBlock defines policy on a particular IPBlock. If this field is set then neither of the other fields can be.

*IPBlock describes a particular CIDR (Ex. "192.168.1.0/24","2001:db8::/64") that is allowed to the pods matched by a NetworkPolicySpec's podSelector. The except entry describes CIDRs that should not be included within this rule.*

- **egress.to.ipBlock.cidr** (string), required

cidr is a string representing the IPBlock Valid examples are "192.168.1.0/24" or "2001:db8::/64"

- **egress.to.ipBlock.except** ([]string)

except is a slice of CIDRs that should not be included within an IPBlock Valid examples are "192.168.1.0/24" or "2001:db8::/64" Except values will be rejected if they are outside the cidr range

- **egress.to.namespaceSelector** ([LabelSelector](#))

namespaceSelector selects namespaces using cluster-scoped labels. This field follows standard label selector semantics; if present but empty, it selects all namespaces.

If podSelector is also set, then the NetworkPolicyPeer as a whole selects the pods matching podSelector in the namespaces selected by namespaceSelector. Otherwise it selects all pods in the namespaces selected by namespaceSelector.

- **egress.to.podSelector** ([LabelSelector](#))

podSelector is a label selector which selects pods. This field follows standard label selector semantics; if present but empty, it selects all pods.

If namespaceSelector is also set, then the NetworkPolicyPeer as a whole selects the pods matching podSelector in the Namespaces selected by NamespaceSelector. Otherwise it selects the pods matching podSelector in the policy's own namespace.

- **egress.ports** ([]NetworkPolicyPort)

ports is a list of destination ports for outgoing traffic. Each item in this list is combined using a logical OR. If this field is empty or missing, this rule matches all ports (traffic not restricted by port). If this field is present and contains at least one item, then this rule allows traffic only if the traffic matches at least one port in the list.

*NetworkPolicyPort describes a port to allow traffic on*

- **egress.ports.port** (IntOrString)

port represents the port on the given protocol. This can either be a numerical or named port on a pod. If this field is not provided, this matches all port names and numbers. If present, only traffic on the specified protocol AND port will be matched.

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **egress.ports.endPort** (int32)

endPort indicates that the range of ports from port to endPort if set, inclusive, should be allowed by the policy. This field cannot be defined if the port field is not defined or if the port field is defined as a named (string) port. The endPort must be equal or greater than port.

- **egress.ports.protocol** (string)

protocol represents the protocol (TCP, UDP, or SCTP) which traffic must match. If not specified, this field defaults to TCP.

# NetworkPolicyList

NetworkPolicyList is a list of NetworkPolicy objects.

---

- **apiVersion:** networking.k8s.io/v1
- **kind:** NetworkPolicyList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]NetworkPolicy](#)), required
- items is a list of schema objects.

# PodDisruptionBudget

PodDisruptionBudget is an object to define the max disruption that can be caused to a collection of pods.

apiVersion: policy/v1

```
import "k8s.io/api/policy/v1"
```

## PodDisruptionBudget

PodDisruptionBudget is an object to define the max disruption that can be caused to a collection of pods

- 
- **apiVersion**: policy/v1

**kind:** PodDisruptionBudget

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PodDisruptionBudgetSpec](#))

Specification of the desired behavior of the PodDisruptionBudget.

- **status** ([PodDisruptionBudgetStatus](#))

Most recently observed status of the PodDisruptionBudget.

## PodDisruptionBudgetSpec

PodDisruptionBudgetSpec is a description of a PodDisruptionBudget.

---

- **maxUnavailable** (IntOrString)

An eviction is allowed if at most "maxUnavailable" pods selected by "selector" are unavailable after the eviction, i.e. even in absence of the evicted pod. For example, one can prevent all voluntary evictions by specifying 0. This is a mutually exclusive setting with "minAvailable".

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **minAvailable** (IntOrString)

An eviction is allowed if at least "minAvailable" pods selected by "selector" will still be available after the eviction, i.e. even in the absence of the evicted pod. So for example you can prevent all voluntary evictions by specifying "100%".

*IntOrString is a type that can hold an int32 or a string. When used in JSON or YAML marshalling and unmarshalling, it produces or consumes the inner type. This allows you to have, for example, a JSON field that can accept a name or number.*

- **selector** ([LabelSelector](#))

Label query over pods whose evictions are managed by the disruption budget. A null selector will match no pods, while an empty ({} ) selector will select all pods within the namespace.

- **unhealthyPodEvictionPolicy** (string)

UnhealthyPodEvictionPolicy defines the criteria for when unhealthy pods should be considered for eviction. Current implementation considers healthy pods, as pods that have status.conditions item with type="Ready",status="True".

Valid policies are `IfHealthyBudget` and `AlwaysAllow`. If no policy is specified, the default behavior will be used, which corresponds to the `IfHealthyBudget` policy.

`IfHealthyBudget` policy means that running pods (`status.phase="Running"`), but not yet healthy can be evicted only if the guarded application is not disrupted (`status.currentHealthy` is at least equal to `status.desiredHealthy`). Healthy pods will be subject to the PDB for eviction.

`AlwaysAllow` policy means that all running pods (`status.phase="Running"`), but not yet healthy are considered disrupted and can be evicted regardless of whether the criteria in a PDB is met. This means perspective running pods of a disrupted application might not get a chance to become healthy. Healthy pods will be subject to the PDB for eviction.

Additional policies may be added in the future. Clients making eviction decisions should disallow eviction of unhealthy pods if they encounter an unrecognized policy in this field.

This field is beta-level. The eviction API uses this field when the feature gate `PDBUnhealthyPodEvictionPolicy` is enabled (enabled by default).

## PodDisruptionBudgetStatus

`PodDisruptionBudgetStatus` represents information about the status of a `PodDisruptionBudget`. Status may trail the actual state of a system.

---

- **currentHealthy** (int32), required  
current number of healthy pods
- **desiredHealthy** (int32), required  
minimum desired number of healthy pods
- **disruptionsAllowed** (int32), required  
Number of pod disruptions that are currently allowed.
- **expectedPods** (int32), required  
total number of pods counted by this disruption budget
- **conditions** ([]Condition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

Conditions contain conditions for PDB. The disruption controller sets the `DisruptionAllowed` condition. The following are known values for the reason field (additional reasons could be added in the future): - `SyncFailed`: The controller

encountered an error and wasn't able to compute the number of allowed disruptions. Therefore no disruptions are allowed and the status of the condition will be False.

- **InsufficientPods**: The number of pods are either at or below the number required by the PodDisruptionBudget. No disruptions are allowed and the status of the condition will be False.
- **SufficientPods**: There are more pods than required by the PodDisruptionBudget. The condition will be True, and the number of allowed disruptions are provided by the disruptionsAllowed property.

*Condition contains details for one aspect of the current state of this API Resource.*

- **conditions.lastTransitionTime** (Time), required

lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string), required

message is a human readable message indicating details about the transition. This may be an empty string.

- **conditions.reason** (string), required

reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

- **conditions.status** (string), required

status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

type of condition in CamelCase or in foo.example.com/CamelCase.

- **conditions.observedGeneration** (int64)

observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

- **disruptedPods** (map[string]Time)

DisruptedPods contains information about pods whose eviction was processed by the API server eviction subresource handler but has not yet been observed by the PodDisruptionBudget controller. A pod will be in this map from the time when the API server processed the eviction request to the time when the pod is seen by PDB controller

as having been marked for deletion (or after a timeout). The key in the map is the name of the pod and the value is the time when the API server processed the eviction request. If the deletion didn't occur and a pod is still there it will be removed from the list automatically by PodDisruptionBudget controller after some time. If everything goes smooth this map should be empty for the most of the time. Large number of entries in the map may indicate problems with pod deletions.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **observedGeneration** (int64)

Most recent generation observed when updating this PDB status. DisruptionsAllowed and other status information is valid only if observedGeneration equals to PDB's object generation.

## PodDisruptionBudgetList

PodDisruptionBudgetList is a collection of PodDisruptionBudgets.

---

- **apiVersion:** policy/v1
- **kind:** PodDisruptionBudgetList
- **metadata** ([ListMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([][PodDisruptionBudget](#)), required

Items is a list of PodDisruptionBudgets

## Operations

# IPAddress v1alpha1

IPAddress represents a single IP of a single IP Family.

apiVersion: networking.k8s.io/v1alpha1

```
import "k8s.io/api/networking/v1alpha1"
```

## IPAddress

IPAddress represents a single IP of a single IP Family. The object is designed to be used by APIs that operate on IP addresses. The object is used by the Service core API for allocation of IP addresses. An IP address can be represented in different formats, to guarantee the uniqueness of the IP, the name of the object is the IP address in canonical format, four decimal digits separated by dots suppressing leading zeros for IPv4 and the representation defined by RFC 5952 for IPv6. Valid: 192.168.1.5 or 2001:db8::1 or 2001:db8:aaaa:bbbb:cccc:dddd:eeee:1 Invalid: 10.01.2.3 or 2001:db8:0:0:0::1

- 
- **apiVersion:** networking.k8s.io/v1alpha1

- **kind:** IPAddress

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([IPAddressSpec](#))

spec is the desired state of the IPAddress. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## IPAddressSpec

IPAddressSpec describe the attributes in an IP Address.

- 
- **parentRef** ([ParentReference](#))

ParentRef references the resource that an IPAddress is attached to. An IPAddress must reference a parent object.

*ParentReference describes a reference to a parent object.*

- **parentRef.group** (string)

Group is the group of the object being referenced.

- **parentRef.name** (string)

Name is the name of the object being referenced.

- **parentRef.namespace** (string)  
Namespace is the namespace of the object being referenced.
- **parentRef.resource** (string)  
Resource is the resource of the object being referenced.
- **parentRef.uid** (string)  
UID is the uid of the object being referenced.

## IPAddressList

IPAddressList contains a list of IPAddress.

- 
- **apiVersion:** networking.k8s.io/v1alpha1
  - **kind:** IPAddressList
  - **metadata** ([ListMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]IPAddress](#)), required  
items is the list of IPAddresses.

## Operations

---

### get read the specified IPAddress

#### HTTP Request

GET /apis/networking.k8s.io/v1alpha1/ipaddresses/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the IPAddress
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([IPAddress](#)): OK

401: Unauthorized

## list list or watch objects of kind IPAddress

### HTTP Request

GET /apis/networking.k8s.io/v1alpha1/ipaddresses

### Parameters

# Extend Resources

---

## [CustomResourceDefinition](#)

CustomResourceDefinition represents a resource that should be exposed on the API server.

## [MutatingWebhookConfiguration](#)

MutatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and may change the object.

## [ValidatingWebhookConfiguration](#)

ValidatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and object without changing it.

## [ValidatingAdmissionPolicy v1beta1](#)

ValidatingAdmissionPolicy describes the definition of an admission validation policy that accepts or rejects an object without changing it.

# CustomResourceDefinition

CustomResourceDefinition represents a resource that should be exposed on the API server.

```
apiVersion: apiextensions.k8s.io/v1
```

```
import "k8s.io/apiextensions-apiserver/pkg/apis/apiextensions/v1"
```

## CustomResourceDefinition

CustomResourceDefinition represents a resource that should be exposed on the API server. Its name MUST be in the format `<.spec.name>.<.spec.group>`.

---

- **apiVersion:** apiextensions.k8s.io/v1
- **kind:** CustomResourceDefinition
- **metadata** ([ObjectMeta](#))

Standard object's metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([CustomResourceDefinitionSpec](#)), required

spec describes how the user wants the resources to appear

- **status** ([CustomResourceDefinitionStatus](#))

status indicates the actual state of the CustomResourceDefinition

## CustomResourceDefinitionSpec

CustomResourceDefinitionSpec describes how a user wants their resource to appear

---

- **group** (string), required

group is the API group of the defined custom resource. The custom resources are served under `/apis/<group>/...`. Must match the name of the CustomResourceDefinition (in the form `<names.plural>.<group>`).

- **names** ([CustomResourceDefinitionNames](#)), required

names specify the resource and kind names for the custom resource.

*CustomResourceDefinitionNames indicates the names to serve this CustomResourceDefinition*

- **names.kind** (string), required

kind is the serialized kind of the resource. It is normally CamelCase and singular. Custom resource instances will use this value as the kind attribute in API calls.

- **names.plural** (string), required

plural is the plural name of the resource to serve. The custom resources are served under `/apis/<group>/<version>/.../<plural>`. Must match the name of the CustomResourceDefinition (in the form `<names.plural>.<group>`). Must be all lowercase.

- **names.categories** ([]string)

categories is a list of grouped resources this custom resource belongs to (e.g. 'all'). This is published in API discovery documents, and used by clients to support invocations like `kubectl get all`.

- **names.listKind** (string)

listKind is the serialized kind of the list for this resource. Defaults to "kindList".

- **names.shortNames** ([]string)

shortNames are short names for the resource, exposed in API discovery documents, and used by clients to support invocations like `kubectl get <shortname>`. It must be all lowercase.

- **names.singular** (string)

singular is the singular name of the resource. It must be all lowercase. Defaults to lowercased kind.

- **scope** (string), required

scope indicates whether the defined custom resource is cluster- or namespace-scoped. Allowed values are Cluster and Namespaced.

- **versions** ([]CustomResourceDefinitionVersion), required

versions is the list of all API versions of the defined custom resource. Version names are used to compute the order in which served versions are listed in API discovery. If the version string is "kube-like", it will sort above non "kube-like" version strings, which are ordered lexicographically. "Kube-like" versions start with a "v", then are followed by a number (the major version), then optionally the string "alpha" or "beta" and another number (the minor version). These are sorted first by GA > beta > alpha (where GA is a version with no suffix such as beta or alpha), and then by comparing major version, then minor version. An example sorted list of versions: v10, v2, v1, v11beta2, v10beta3, v3beta1, v12alpha1, v11alpha2, foo1, foo10.

*CustomResourceDefinitionVersion describes a version for CRD.*

- **versions.name** (string), required

name is the version name, e.g. "v1", "v2beta1", etc. The custom resources are served under this version at `/apis/<group>/<version>/...` if served is true.

- **versions.served** (boolean), required

served is a flag enabling/disabling this version from being served via REST APIs

- **versions.storage** (boolean), required

storage indicates this version should be used when persisting custom resources to storage. There must be exactly one version with storage=true.

- **versions.additionalPrinterColumns** ([]CustomResourceColumnDefinition)

additionalPrinterColumns specifies additional columns returned in Table output. See <https://kubernetes.io/docs/reference/using-api/api-concepts/#receiving-resources-as-tables> for details. If no columns are specified, a single column displaying the age of the custom resource is used.

*CustomResourceColumnDefinition specifies a column for server side printing.*

- **versions.additionalPrinterColumns.jsonPath** (string), required

jsonPath is a simple JSON path (i.e. with array notation) which is evaluated against each custom resource to produce the value for this column.

- **versions.additionalPrinterColumns.name** (string), required
  - name is a human readable name for the column.
- **versions.additionalPrinterColumns.type** (string), required
  - type is an OpenAPI type definition for this column. See <https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md#data-types> for details.
- **versions.additionalPrinterColumns.description** (string)
  - description is a human readable description of this column.
- **versions.additionalPrinterColumns.format** (string)
  - format is an optional OpenAPI type definition for this column. The 'name' format is applied to the primary identifier column to assist in clients identifying column is the resource name. See <https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md#data-types> for details.
- **versions.additionalPrinterColumns.priority** (int32)
  - priority is an integer defining the relative importance of this column compared to others. Lower numbers are considered higher priority. Columns that may be omitted in limited space scenarios should be given a priority greater than 0.
- **versions.deprecated** (boolean)
  - deprecated indicates this version of the custom resource API is deprecated. When set to true, API requests to this version receive a warning header in the server response. Defaults to false.
- **versions.deprecationWarning** (string)
  - deprecationWarning overrides the default warning returned to API clients. May only be set when deprecated is true. The default warning indicates this version is deprecated and recommends use of the newest served version of equal or greater stability, if one exists.
- **versions.schema** (CustomResourceValidation)
  - schema describes the schema used for validation, pruning, and defaulting of this version of the custom resource.
  - *CustomResourceValidation is a list of validation methods for CustomResources.*
  - **versions.schema.openAPIV3Schema** ([JSONSchemaProps](#))
    - openAPIV3Schema is the OpenAPI v3 schema to use for validation and pruning.
- **versions.subresources** (CustomResourceSubresources)

subresources specify what subresources this version of the defined custom resource have.

*CustomResourceSubresources* defines the status and scale subresources for *CustomResources*.

- **versions.subresources.scale** (*CustomResourceSubresourceScale*)

scale indicates the custom resource should serve a `/scale` subresource that returns an autoscaling/v1 Scale object.

*CustomResourceSubresourceScale* defines how to serve the scale subresource for *CustomResources*.

- **versions.subresources.scale.specReplicasPath** (string), required

specReplicasPath defines the JSON path inside of a custom resource that corresponds to Scale spec.replicas. Only JSON paths without the array notation are allowed. Must be a JSON Path under .spec. If there is no value under the given path in the custom resource, the `/scale` subresource will return an error on GET.

- **versions.subresources.scale.statusReplicasPath** (string), required

statusReplicasPath defines the JSON path inside of a custom resource that corresponds to Scale status.replicas. Only JSON paths without the array notation are allowed. Must be a JSON Path under .status. If there is no value under the given path in the custom resource, the status.replicas value in the `/scale` subresource will default to 0.

- **versions.subresources.scale.labelSelectorPath** (string)

labelSelectorPath defines the JSON path inside of a custom resource that corresponds to Scale status.selector. Only JSON paths without the array notation are allowed. Must be a JSON Path under .status or .spec. Must be set to work with HorizontalPodAutoscaler. The field pointed by this JSON path must be a string field (not a complex selector struct) which contains a serialized label selector in string form. More info: <https://kubernetes.io/docs/tasks/access-kubernetes-api/custom-resources/custom-resource-definitions#scale-subresource> If there is no value under the given path in the custom resource, the status.selector value in the `/scale` subresource will default to the empty string.

- **versions.subresources.status** (*CustomResourceSubresourceStatus*)

status indicates the custom resource should serve a `/status` subresource. When enabled: 1. requests to the custom resource primary endpoint ignore changes to the status stanza of the object. 2. requests to the custom resource `/status` subresource ignore changes to anything other than the status stanza of the object.

*CustomResourceSubresourceStatus* defines how to serve the status subresource for *CustomResources*. Status is represented by the `.status` JSON path inside of a *CustomResource*. When set, \* exposes a `/status` subresource for the custom

*resource \* PUT requests to the /status subresource take a custom resource object, and ignore changes to anything except the status stanza \* PUT/POST/PATCH requests to the custom resource ignore changes to the status stanza*

- **conversion** (CustomResourceConversion)

conversion defines conversion settings for the CRD.

*CustomResourceConversion describes how to convert different versions of a CR.*

- **conversion.strategy** (string), required

strategy specifies how custom resources are converted between versions. Allowed values are: - "None": The converter only change the apiVersion and would not touch any other field in the custom resource. - "Webhook": API Server will call to an external webhook to do the conversion. Additional information is needed for this option. This requires spec.preserveUnknownFields to be false, and spec.conversion.webhook to be set.

- **conversion.webhook** (WebhookConversion)

webhook describes how to call the conversion webhook. Required when strategy is set to "Webhook".

*WebhookConversion describes how to call a conversion webhook*

- **conversion.webhook.conversionReviewVersions** ([]string), required

conversionReviewVersions is an ordered list of preferred ConversionReview versions the Webhook expects. The API server will use the first version in the list which it supports. If none of the versions specified in this list are supported by API server, conversion will fail for the custom resource. If a persisted Webhook configuration specifies allowed versions and does not include any versions known to the API Server, calls to the webhook will fail.

- **conversion.webhook.clientConfig** (WebhookClientConfig)

clientConfig is the instructions for how to call the webhook if strategy is Webhook.

*WebhookClientConfig contains the information to make a TLS connection with the webhook.*

- **conversion.webhook.clientConfig.caBundle** ([]byte)

caBundle is a PEM encoded CA bundle which will be used to validate the webhook's server certificate. If unspecified, system trust roots on the apiserver are used.

- **conversion.webhook.clientConfig.service** (ServiceReference)

service is a reference to the service for this webhook. Either service or url must be specified.

If the webhook is running within the cluster, then you should use service.

*ServiceReference holds a reference to Service.legacy.k8s.io*

- **conversion.webhook.clientConfig.service.name** (string), required

name is the name of the service. Required

- **conversion.webhook.clientConfig.service.namespace** (string), required

namespace is the namespace of the service. Required

- **conversion.webhook.clientConfig.service.path** (string)

path is an optional URL path at which the webhook will be contacted.

- **conversion.webhook.clientConfig.service.port** (int32)

port is an optional service port at which the webhook will be contacted. port should be a valid port number (1-65535, inclusive). Defaults to 443 for backward compatibility.

- **conversion.webhook.clientConfig.url** (string)

url gives the location of the webhook, in standard URL form (scheme://host:port/path). Exactly one of url or service must be specified.

The host should not refer to a service running in the cluster; use the service field instead. The host might be resolved via external DNS in some apiservers (e.g., kube-apiserver cannot resolve in-cluster DNS as that would be a layering violation). host may also be an IP address.

Please note that using localhost or 127.0.0.1 as a host is risky unless you take great care to run this webhook on all hosts which run an apiserver which might need to make calls to this webhook. Such installs are likely to be non-portable, i.e., not easy to turn up in a new cluster.

The scheme must be "https"; the URL must begin with "https://".

A path is optional, and if present may be any string permissible in a URL. You may use the path to pass an arbitrary string to the webhook, for example, a cluster identifier.

Attempting to use a user or basic auth e.g. "user:password@" is not allowed. Fragments ("#...") and query parameters ("?...") are not allowed, either.

- **preserveUnknownFields** (boolean)

preserveUnknownFields indicates that object fields which are not specified in the OpenAPI schema should be preserved when persisting to storage. apiVersion, kind, metadata and known fields inside metadata are always preserved. This field is deprecated in favor of setting x-preserve-unknown-fields to true in spec.versions[\*].schema.openAPIV3Schema. See <https://kubernetes.io/docs/tasks/extend-kubernetes/custom-resources/custom-resource-definitions/#field-pruning> for details.

## JSONSchemaProps

JSONSchemaProps is a JSON-Schema following Specification Draft 4 (<http://json-schema.org/>).

---

- **\$ref** (string)
- **\$schema** (string)
- **additionalItems** (JSONSchemaPropsOrBool)

*JSONSchemaPropsOrBool represents JSONSchemaProps or a boolean value. Defaults to true for the boolean property.*

- **additionalProperties** (JSONSchemaPropsOrBool)

*JSONSchemaPropsOrBool represents JSONSchemaProps or a boolean value. Defaults to true for the boolean property.*

- **allOf** ([][JSONSchemaProps](#))
- **anyOf** ([][JSONSchemaProps](#))
- **default** (JSON)

default is a default value for undefined object fields. Defaulting is a beta feature under the CustomResourceDefaulting feature gate. Defaulting requires spec.preserveUnknownFields to be false.

*JSON represents any valid JSON value. These types are supported: bool, int64, float64, string, []interface{}, map[string]interface{} and nil.*

- **definitions** (map[string][JSONSchemaProps](#))
- **dependencies** (map[string]JSONSchemaPropsOrStringArray)

*JSONSchemaPropsOrStringArray represents a JSONSchemaProps or a string array.*

- **description** (string)
- **enum** ([]JSON)

*JSON represents any valid JSON value. These types are supported: bool, int64, float64, string, []interface{}, map[string]interface{} and nil.*

- **example** (JSON)

*JSON represents any valid JSON value. These types are supported: bool, int64, float64, string, []interface{}, map[string]interface{} and nil.*

- **exclusiveMaximum** (boolean)
- **exclusiveMinimum** (boolean)
- **externalDocs** (ExternalDocumentation)

*ExternalDocumentation allows referencing an external resource for extended documentation.*

- **externalDocs.description** (string)
- **externalDocs.url** (string)

- **format** (string)

format is an OpenAPI v3 format string. Unknown formats are ignored. The following formats are validated:

- **bsonobjectid**: a bson object ID, i.e. a 24 characters hex string - **uri**: an URI as parsed by Golang net/url.ParseRequestURI - **email**: an email address as parsed by Golang net/mail.ParseAddress - **hostname**: a valid representation for an Internet host name, as defined by RFC 1034, section 3.1 [RFC1034]. - **ipv4**: an IPv4 IP as parsed by Golang net.ParseIP - **ipv6**: an IPv6 IP as parsed by Golang net.ParseIP - **cidr**: a CIDR as parsed by Golang net.ParseCIDR - **mac**: a MAC address as parsed by Golang net.ParseMAC - **uuid**: an UUID that allows uppercase defined by the regex `(?i)^[0-9a-f]{8}-?[0-9a-f]{4}-?[0-9a-f]{4}-?[0-9a-f]{12}$` - **uuid3**: an UUID3 that allows uppercase defined by the regex `(?i)^[0-9a-f]{8}-?[0-9a-f]{4}-?3[0-9a-f]{3}-?[0-9a-f]{4}-?[0-9a-f]{12}$` - **uuid4**: an UUID4 that allows uppercase defined by the regex `(?i)^[0-9a-f]{8}-?[0-9a-f]{4}-?4[0-9a-f]{3}-?[89ab][0-9a-f]{3}-?[0-9a-f]{12}$` - **uuid5**: an UUID5 that allows uppercase defined by the regex `(?i)^[0-9a-f]{8}-?[0-9a-f]{4}-?5[0-9a-f]{3}-?[89ab][0-9a-f]{3}-?[0-9a-f]{12}$` - **isbn**: an ISBN10 or ISBN13 number string like "0321751043" or "978-0321751041" - **isbn10**: an ISBN10 number string like "0321751043" - **isbn13**: an ISBN13 number string like "978-0321751041" - **creditcard**: a credit card number defined by the regex `^(?:4[0-9]{12}(?:[0-9]{3})?|5[1-5][0-9]{14}|6(?:011|5[0-9][0-9])[0-9]{12}|3[47][0-9]{13}|3(?:0[0-5]||[68][0-9])[0-9]{11})(?:2131|1800|35\d{3})\d{11}$` with any non digit characters mixed in - **ssn**: a U.S. social security number following the regex `^\d{3}[- ]?\d{2}[- ]?\d{4}$` - **hexcolor**: an hexadecimal color code like "#FFFFFF" following the regex `^#?([0-9a-fA-F]{3}|[0-9a-fA-F]{6})$` - **rgbcolor**: an RGB color code like rgb like "rgb(255,255,255)" - **byte**: base64 encoded binary data - **password**: any kind of string - **date**: a date string like "2006-01-02" as defined by full-date in RFC3339 - **duration**: a duration string like "22 ns" as parsed by Golang time.ParseDuration or compatible with Scala duration format - **datetime**: a date time string like "2014-12-15T19:30:20.000Z" as defined by date-time in RFC3339.

- **id** (string)
- **items** (JSONSchemaPropsOrArray)

*JSONSchemaPropsOrArray represents a value that can either be a JSONSchemaProps or an array of JSONSchemaProps. Mainly here for serialization purposes.*

- **maxItems** (int64)
- **maxLength** (int64)
- **maxProperties** (int64)
- **maximum** (double)
- **minItems** (int64)
- **minLength** (int64)
- **minProperties** (int64)
- **minimum** (double)
- **multipleOf** (double)
- **not** ([JSONSchemaProps](#))
- **nullable** (boolean)
- **oneOf** ([\[\]JSONSchemaProps](#))
- **pattern** (string)
- **patternProperties** (map[string][JSONSchemaProps](#))
- **properties** (map[string][JSONSchemaProps](#))
- **required** ([\[\]string](#))
- **title** (string)
- **type** (string)
- **uniqueItems** (boolean)
- **x-kubernetes-embedded-resource** (boolean)

x-kubernetes-embedded-resource defines that the value is an embedded Kubernetes runtime.Object, with TypeMeta and ObjectMeta. The type must be object. It is allowed to further restrict the embedded object. kind, apiVersion and metadata are validated automatically. x-kubernetes-preserve-unknown-fields is allowed to be true, but does not have to be if the object is fully specified (up to kind, apiVersion, metadata).

- **x-kubernetes-int-or-string** (boolean)

x-kubernetes-int-or-string specifies that this value is either an integer or a string. If this is true, an empty type is allowed and type as child of anyOf is permitted if following one of the following patterns:

1. anyOf:
  - type: integer
  - type: string

2. allOf:

- anyOf:
  - type: integer
  - type: string
- ... zero or more

- **x-kubernetes-list-map-keys** ([]string)

x-kubernetes-list-map-keys annotates an array with the x-kubernetes-list-type map by specifying the keys used as the index of the map.

This tag MUST only be used on lists that have the "x-kubernetes-list-type" extension set to "map". Also, the values specified for this attribute must be a scalar typed field of the child structure (no nesting is supported).

The properties specified must either be required or have a default value, to ensure those properties are present for all list items.

- **x-kubernetes-list-type** (string)

x-kubernetes-list-type annotates an array to further describe its topology. This extension must only be used on lists and may have 3 possible values:

1. atomic: the list is treated as a single entity, like a scalar. Atomic lists will be entirely replaced when updated. This extension may be used on any type of list (struct, scalar, ...).
2. set: Sets are lists that must not have multiple items with the same value. Each value must be a scalar, an object with x-kubernetes-map-type atomic or an array with x-kubernetes-list-type atomic.
3. map: These lists are like maps in that their elements have a non-index key used to identify them. Order is preserved upon merge. The map tag must only be used on a list with elements of type object. Defaults to atomic for arrays.

- **x-kubernetes-map-type** (string)

x-kubernetes-map-type annotates an object to further describe its topology. This extension must only be used when type is object and may have 2 possible values:

1. granular: These maps are actual maps (key-value pairs) and each fields are independent from each other (they can each be manipulated by separate actors). This is the default behaviour for all maps.
2. atomic: the list is treated as a single entity, like a scalar. Atomic maps will be entirely replaced when updated.

- **x-kubernetes-preserve-unknown-fields** (boolean)

x-kubernetes-preserve-unknown-fields stops the API server decoding step from pruning fields which are not specified in the validation schema. This affects fields recursively, but switches back to normal pruning behaviour if nested properties or additionalProperties are specified in the schema. This can either be true or undefined. False is forbidden.

- **x-kubernetes-validations** ([]ValidationRule)

*Patch strategy: merge on key rule*

*Map: unique values on key rule will be kept during a merge*

x-kubernetes-validations describes a list of validation rules written in the CEL expression language. This field is an alpha-level. Using this field requires the feature gate CustomResourceValidationExpressions to be enabled.

*ValidationRule describes a validation rule written in the CEL expression language.*

- **x-kubernetes-validations.rule** (string), required

Rule represents the expression which will be evaluated by CEL. ref: <https://github.com/google/cel-spec> The Rule is scoped to the location of the x-kubernetes-validations extension in the schema. The self variable in the CEL expression is bound to the scoped value. Example: - Rule scoped to the root of a resource with a status subresource: {"rule": "self.status.actual <= self.spec.maxDesired"}

If the Rule is scoped to an object with properties, the accessible properties of the object are field selectable via self.field and field presence can be checked via has(self.field). Null valued fields are treated as absent fields in CEL expressions. If the Rule is scoped to an object with additionalProperties (i.e. a map) the value of the map are accessible via self[mapKey], map containment can be checked via mapKey in self and all entries of the map are accessible via CEL macros and functions such as self.all(...). If the Rule is scoped to an array, the elements of the array are accessible via self[i] and also by macros and functions. If the Rule is scoped to a scalar, self is bound to the scalar value. Examples: - Rule scoped to a map of objects: {"rule": "self.components['Widget'].priority < 10"} - Rule scoped to a list of integers: {"rule": "self.values.all(value, value >= 0 && value < 100)"} - Rule scoped to a string value: {"rule": "self.startsWith('kube')"}

The apiVersion, kind, metadata.name and metadata.generateName are always accessible from the root of the object and from any x-kubernetes-embedded-resource annotated objects. No other metadata properties are accessible.

Unknown data preserved in custom resources via x-kubernetes-preserve-unknown-fields is not accessible in CEL expressions. This includes: - Unknown field values that are preserved by object schemas with x-kubernetes-preserve-unknown-fields. - Object properties where the property schema is of an "unknown type". An "unknown type" is recursively defined as:

- A schema with no type and x-kubernetes-preserve-unknown-fields set to true
- An array where the items schema is of an "unknown type"
- An object where the additionalProperties schema is of an "unknown type"

Only property names of the form [a-zA-Z\_./][a-zA-Z0-9\_./]\* are accessible.

Accessible property names are escaped according to the following rules when accessed in the expression: - " **escapes to 'underscores'** - ' **escapes to 'dot'** - ' **escapes to 'dash'** - '/' **escapes to 'slash'** - **Property names that exactly match a CEL RESERVED keyword escape to '{keyword}\_\_'**. The keywords are: "true", "false", "null", "in", "as", "break", "const", "continue", "else", "for", "function", "if", "import", "let", "loop", "package", "namespace", "return". Examples:

- Rule accessing a property named "namespace": {"rule": "self.namespace > 0"}
- Rule accessing a property named "x-prop": {"rule": "self.x\_\_dash\_\_prop > 0"}

- Rule accessing a property named "redact\_\_d": {"rule": "self.redact\_\_underscores\_\_d > 0"}

Equality on arrays with x-kubernetes-list-type of 'set' or 'map' ignores element order, i.e. [1, 2] == [2, 1]. Concatenation on arrays with x-kubernetes-list-type use the semantics of the list type:

- 'set':  $X + Y$  performs a union where the array positions of all elements in  $X$  are preserved and non-intersecting elements in  $Y$  are appended, retaining their partial order.
- 'map':  $X + Y$  performs a merge where the array positions of all keys in  $X$  are preserved but the values are overwritten by values in  $Y$  when the key sets of  $X$  and  $Y$  intersect. Elements in  $Y$  with non-intersecting keys are appended, retaining their partial order.

◦ **x-kubernetes-validations.fieldPath** (string)

fieldPath represents the field path returned when the validation fails. It must be a relative JSON path (i.e. with array notation) scoped to the location of this x-kubernetes-validations extension in the schema and refer to an existing field. e.g. when validation checks if a specific attribute foo under a map testMap, the fieldPath could be set to .testMap.foo If the validation checks two lists must have unique attributes, the fieldPath could be set to either of the list: e.g. .testList It does not support list numeric index. It supports child operation to refer to an existing field currently. Refer to [JSONPath support in Kubernetes](#) for more info. Numeric index of array is not supported. For field name which contains special characters, use ['specialName'] to refer the field name. e.g. for attribute foo.34\$ appears in a list testList, the fieldPath could be set to .testList['foo.34\$']

◦ **x-kubernetes-validations.message** (string)

Message represents the message displayed when validation fails. The message is required if the Rule contains line breaks. The message must not contain line breaks. If unset, the message is "failed rule: {Rule}". e.g. "must be a URL with the host matching spec.host"

◦ **x-kubernetes-validations.messageExpression** (string)

MessageExpression declares a CEL expression that evaluates to the validation failure message that is returned when this rule fails. Since messageExpression is used as a failure message, it must evaluate to a string. If both message and messageExpression are present on a rule, then messageExpression will be used if validation fails. If messageExpression results in a runtime error, the runtime error is logged, and the validation failure message is produced as if the messageExpression field were unset. If messageExpression evaluates to an empty string, a string with only spaces, or a string that contains line breaks, then the validation failure message will also be produced as if the messageExpression field were unset, and the fact that messageExpression produced an empty string/string with only spaces/string with line breaks will be logged. messageExpression has access to all the same variables as the rule; the only difference is the return type. Example: "x must be less than max (" + string(self.max) + ")"

◦ **x-kubernetes-validations.reason** (string)

reason provides a machine-readable validation failure reason that is returned to the caller when a request fails this validation rule. The HTTP status code returned to the caller will match the reason of the first failed validation rule. The currently supported reasons are: "FieldValueInvalid", "FieldValueForbidden", "FieldValueRequired", "FieldValueDuplicate". If not set, default to use "FieldValueInvalid". All future added reasons must be accepted by clients when reading this value and unknown reasons should be treated as FieldValueInvalid.

## CustomResourceDefinitionStatus

CustomResourceDefinitionStatus indicates the state of the CustomResourceDefinition

---

- **acceptedNames** (CustomResourceDefinitionNames)

acceptedNames are the names that are actually being used to serve discovery. They may be different than the names in spec.

*CustomResourceDefinitionNames indicates the names to serve this CustomResourceDefinition*

- **acceptedNames.kind** (string), required

kind is the serialized kind of the resource. It is normally CamelCase and singular. Custom resource instances will use this value as the kind attribute in API calls.

- **acceptedNames.plural** (string), required

plural is the plural name of the resource to serve. The custom resources are served under /apis/<group>/<version>/.../<plural>. Must match the name of the CustomResourceDefinition (in the form <names.plural>.<group>). Must be all lowercase.

- **acceptedNames.categories** ([]string)

categories is a list of grouped resources this custom resource belongs to (e.g. 'all'). This is published in API discovery documents, and used by clients to support invocations like kubectl get all.

- **acceptedNames.listKind** (string)

listKind is the serialized kind of the list for this resource. Defaults to "kindList".

- **acceptedNames.shortNames** ([]string)

shortNames are short names for the resource, exposed in API discovery documents, and used by clients to support invocations like kubectl get <shortname>. It must be all lowercase.

- **acceptedNames.singular** (string)

singular is the singular name of the resource. It must be all lowercase. Defaults to lowercased kind.

- **conditions** ([]CustomResourceDefinitionCondition)

*Map: unique values on key type will be kept during a merge*

conditions indicate state for particular aspects of a CustomResourceDefinition

*CustomResourceDefinitionCondition contains details for the current condition of this pod.*

- **conditions.status** (string), required

status is the status of the condition. Can be True, False, Unknown.

- **conditions.type** (string), required

type is the type of the condition. Types include Established, NamesAccepted and Terminating.

- **conditions.lastTransitionTime** (Time)

lastTransitionTime last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

message is a human-readable message indicating details about last transition.

- **conditions.reason** (string)

reason is a unique, one-word, CamelCase reason for the condition's last transition.

- **storedVersions** ([]string)

storedVersions lists all versions of CustomResources that were ever persisted. Tracking these versions allows a migration path for stored versions in etcd. The field is mutable so a migration controller can finish a migration to another version (ensuring no old objects are left in storage), and then remove the rest of the versions from this list. Versions may not be removed from spec.versions while they exist in this list.

## CustomResourceDefinitionList

CustomResourceDefinitionList is a list of CustomResourceDefinition objects.

---

- **items** ([][CustomResourceDefinition](#)), required

items list individual CustomResourceDefinition objects

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

**kind** (string)

- Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metadata** ([ListMeta](#))

Standard object's metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

## Operations

---

### get read the specified CustomResourceDefinition

#### HTTP Request

GET /apis/apiextensions.k8s.io/v1/customresourcedefinitions/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the CustomResourceDefinition
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([CustomResourceDefinition](#)): OK

401: Unauthorized

### get read status of the specified CustomResourceDefinition

#### HTTP Request

GET /apis/apiextensions.k8s.io/v1/customresourcedefinitions/{name}/status

#### Parameters

- **name** (*in path*): string, required  
name of the CustomResourceDefinition
- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([CustomResourceDefinition](#)): OK

401: Unauthorized

## list list or watch objects of kind CustomResourceDefinition

## HTTP Request

GET /apis/apiextensions.k8s.io/v1/customresourcedefinitions

## Parameters

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

[fieldSelector](#)

- **labelSelector** (*in query*): string

# MutatingWebhookConfiguration

MutatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and may change the object.

apiVersion: admissionregistration.k8s.io/v1

```
import "k8s.io/api/admissionregistration/v1"
```

## MutatingWebhookConfiguration

MutatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and may change the object.

---

- **apiVersion:** admissionregistration.k8s.io/v1
- **kind:** MutatingWebhookConfiguration
- **metadata** ([ObjectMeta](#))

Standard object metadata; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>.

- **webhooks** ([]MutatingWebhook)

*Patch strategy: merge on key name*

Webhooks is a list of webhooks and the affected resources and operations.

*MutatingWebhook describes an admission webhook and the resources and operations it applies to.*

- **webhooks.admissionReviewVersions** ([]string), required

AdmissionReviewVersions is an ordered list of preferred AdmissionReview versions the Webhook expects. API server will try to use first version in the list which it supports. If none of the versions specified in this list supported by API server, validation will fail for this object. If a persisted webhook configuration specifies allowed versions and does not include any versions known to the API Server, calls to the webhook will fail and be subject to the failure policy.

- **webhooks.clientConfig** (WebhookClientConfig), required

ClientConfig defines how to communicate with the hook. Required

*WebhookClientConfig contains the information to make a TLS connection with the webhook*

- **webhooks.clientConfig.caBundle** ([]byte)

caBundle is a PEM encoded CA bundle which will be used to validate the webhook's server certificate. If unspecified, system trust roots on the apiserver are used.

- **webhooks.clientConfig.service** (ServiceReference)

service is a reference to the service for this webhook. Either service or url must be specified.

If the webhook is running within the cluster, then you should use service.

*ServiceReference holds a reference to Service.legacy.k8s.io*

- **webhooks.clientConfig.service.name** (string), required

name is the name of the service. Required

- **webhooks.clientConfig.service.namespace** (string), required

namespace is the namespace of the service. Required

- **webhooks.clientConfig.service.path** (string)

path is an optional URL path which will be sent in any request to this service.

- **webhooks.clientConfig.service.port** (int32)

If specified, the port on the service that hosting webhook. Default to 443 for backward compatibility. port should be a valid port number (1-65535, inclusive).

- **webhooks.clientConfig.url** (string)

url gives the location of the webhook, in standard URL form (scheme://host:port/path). Exactly one of url or service must be specified.

The host should not refer to a service running in the cluster; use the service field instead. The host might be resolved via external DNS in some apiservers (e.g., kube-apiserver cannot resolve in-cluster DNS as that would be a layering violation). host may also be an IP address.

Please note that using localhost or 127.0.0.1 as a host is risky unless you take great care to run this webhook on all hosts which run an apiserver which might need to make calls to this webhook. Such installs are likely to be non-portable, i.e., not easy to turn up in a new cluster.

The scheme must be "https"; the URL must begin with "https://".

A path is optional, and if present may be any string permissible in a URL. You may use the path to pass an arbitrary string to the webhook, for example, a cluster identifier.

Attempting to use a user or basic auth e.g. "user:password@" is not allowed. Fragments ("#...") and query parameters ("?...") are not allowed, either.

- **webhooks.name** (string), required

The name of the admission webhook. Name should be fully qualified, e.g., imagepolicy.kubernetes.io, where "imagepolicy" is the name of the webhook, and kubernetes.io is the name of the organization. Required.

- **webhooks.sideEffects** (string), required

SideEffects states whether this webhook has side effects. Acceptable values are: None, NoneOnDryRun (webhooks created via v1beta1 may also specify Some or

Unknown). Webhooks with side effects MUST implement a reconciliation system, since a request may be rejected by a future step in the admission chain and the side effects therefore need to be undone. Requests with the dryRun attribute will be auto-rejected if they match a webhook with sideEffects == Unknown or Some.

- **webhooks.failurePolicy** (string)

FailurePolicy defines how unrecognized errors from the admission endpoint are handled - allowed values are Ignore or Fail. Defaults to Fail.

- **webhooks.matchConditions** ([]MatchCondition)

*Patch strategy: merge on key name*

*Map: unique values on key name will be kept during a merge*

MatchConditions is a list of conditions that must be met for a request to be sent to this webhook. Match conditions filter requests that have already been matched by the rules, namespaceSelector, and objectSelector. An empty list of matchConditions matches all requests. There are a maximum of 64 match conditions allowed.

The exact matching logic is (in order):

1. If ANY matchCondition evaluates to FALSE, the webhook is skipped.
2. If ALL matchConditions evaluate to TRUE, the webhook is called.
3. If any matchCondition evaluates to an error (but none are FALSE):
  - If failurePolicy=Fail, reject the request
  - If failurePolicy=Ignore, the error is ignored and the webhook is skipped

This is a beta feature and managed by the AdmissionWebhookMatchConditions feature gate.

*MatchCondition represents a condition which must be fulfilled for a request to be sent to a webhook.*

- **webhooks.matchConditions.expression** (string), required

Expression represents the expression which will be evaluated by CEL. Must evaluate to bool. CEL expressions have access to the contents of the AdmissionRequest and Authorizer, organized into CEL variables:

'object' - The object from the incoming request. The value is null for DELETE requests. 'oldObject' - The existing object. The value is null for CREATE requests. 'request' - Attributes of the admission request (/pkg/apis/admission/types.go#AdmissionRequest). 'authorizer' - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See <https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz> 'authorizer.requestResource' - A CEL ResourceCheck constructed from the 'authorizer' and configured with the request resource. Documentation on CEL: <https://kubernetes.io/docs/reference/using-api/cel/>

Required.

- **webhooks.matchConditions.name** (string), required

Name is an identifier for this match condition, used for strategic merging of MatchConditions, as well as providing an identifier for logging purposes. A good name should be descriptive of the associated expression. Name must be a qualified name consisting of alphanumeric characters, '-', '.' or '\_', and must start and end with an alphanumeric character (e.g. 'MyName', or 'my.name', or '123-abc', regex used for validation is '([A-Za-z0-9](-|\.|\_)?[A-Za-z0-9])' with an optional DNS subdomain prefix and '/' (e.g. 'example.com/MyName')

Required.

- **webhooks.matchPolicy** (string)

matchPolicy defines how the "rules" list is used to match incoming requests. Allowed values are "Exact" or "Equivalent".

- **Exact:** match a request only if it exactly matches a specified rule. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, but "rules" only included apiGroups: ["apps"], apiVersions: ["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would not be sent to the webhook.
- **Equivalent:** match a request if modifies a resource listed in rules, even via another API group or version. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, and "rules" only included apiGroups: ["apps"], apiVersions: ["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would be converted to apps/v1 and sent to the webhook.

Defaults to "Equivalent"

- **webhooks.namespaceSelector** ([LabelSelector](#))

NamespaceSelector decides whether to run the webhook on an object based on whether the namespace for that object matches the selector. If the object itself is a namespace, the matching is performed on object.metadata.labels. If the object is another cluster scoped resource, it never skips the webhook.

For example, to run the webhook on any objects whose namespace is not associated with "runlevel" of "0" or "1"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "runlevel", "operator": "NotIn", "values": [ "0", "1" ] } ] }

If instead you want to only run the webhook on any objects whose namespace is associated with the "environment" of "prod" or "staging"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "environment", "operator": "In", "values": [ "prod", "staging" ] } ] }

See <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/> for more examples of label selectors.

Default to the empty LabelSelector, which matches everything.

- **webhooks.objectSelector** ([LabelSelector](#))

ObjectSelector decides whether to run the webhook based on if the object has matching labels. objectSelector is evaluated against both the oldObject and newObject that would be sent to the webhook, and is considered to match if either object matches the selector. A null object (oldObject in the case of create, or newObject in the case of delete) or an object that cannot have labels (like a DeploymentRollback or a PodProxyOptions object) is not considered to match. Use the object selector only if the webhook is opt-in, because end users may skip the admission webhook by setting the labels. Default to the empty LabelSelector, which matches everything.

- **webhooks.reinvocationPolicy** (string)

reinvocationPolicy indicates whether this webhook should be called multiple times as part of a single admission evaluation. Allowed values are "Never" and "IfNeeded".

Never: the webhook will not be called more than once in a single admission evaluation.

IfNeeded: the webhook will be called at least one additional time as part of the admission evaluation if the object being admitted is modified by other admission plugins after the initial webhook call. Webhooks that specify this option *must* be idempotent, able to process objects they previously admitted. Note: \* the number of additional invocations is not guaranteed to be exactly one. \* if additional invocations result in further modifications to the object, webhooks are not guaranteed to be invoked again. \* webhooks that use this option may be reordered to minimize the number of additional invocations. \* to validate an object after all mutations are guaranteed complete, use a validating admission webhook instead.

Defaults to "Never".

- **webhooks.rules** ([]RuleWithOperations)

Rules describes what operations on what resources/subresources the webhook cares about. The webhook cares about an operation if it matches *any* Rule. However, in order to prevent ValidatingAdmissionWebhooks and MutatingAdmissionWebhooks from putting the cluster in a state which cannot be recovered from without completely disabling the plugin, ValidatingAdmissionWebhooks and MutatingAdmissionWebhooks are never called on admission requests for ValidatingWebhookConfiguration and MutatingWebhookConfiguration objects.

*RuleWithOperations is a tuple of Operations and Resources. It is recommended to make sure that all the tuple expansions are valid.*

- **webhooks.rules.apiGroups** ([]string)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

- **webhooks.rules.apiVersions** ([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

- **webhooks.rules.operations** ([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

- **webhooks.rules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources of pods. '/scale' means all scale subresources. '/' means all resources and their subresources.

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed. Required.

- **webhooks.rules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" "Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule. "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is "".

- **webhooks.timeoutSeconds** (int32)

TimeoutSeconds specifies the timeout for this webhook. After the timeout passes, the webhook call will be ignored or the API call will fail based on the failure policy. The timeout value must be between 1 and 30 seconds. Default to 10 seconds.

## MutatingWebhookConfigurationList

MutatingWebhookConfigurationList is a list of MutatingWebhookConfiguration.

- 
- **apiVersion:** admissionregistration.k8s.io/v1
  - **kind:** MutatingWebhookConfigurationList
  - **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]MutatingWebhookConfiguration](#)), required

List of MutatingWebhookConfiguration.

## Operations

---

### get read the specified MutatingWebhookConfiguration

#### HTTP Request

GET /apis/admissionregistration.k8s.io/v1/mutatingwebhookconfigurations/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the MutatingWebhookConfiguration
- **pretty** (*in query*): string  
[pretty](#)

#### Response

200 ([MutatingWebhookConfiguration](#)): OK

401: Unauthorized

### list list or watch objects of kind MutatingWebhookConfiguration

#### HTTP Request

# ValidatingWebhookConfiguration

ValidatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and object without changing it.

apiVersion: admissionregistration.k8s.io/v1

import "k8s.io/api/admissionregistration/v1"

# ValidatingWebhookConfiguration

ValidatingWebhookConfiguration describes the configuration of and admission webhook that accept or reject and object without changing it.

---

- **apiVersion:** admissionregistration.k8s.io/v1
- **kind:** ValidatingWebhookConfiguration
- **metadata** ([ObjectMeta](#))

Standard object metadata; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>.

- **webhooks** ([]ValidatingWebhook)

*Patch strategy: merge on key name*

Webhooks is a list of webhooks and the affected resources and operations.

*ValidatingWebhook describes an admission webhook and the resources and operations it applies to.*

- **webhooks.admissionReviewVersions** ([]string), required

AdmissionReviewVersions is an ordered list of preferred AdmissionReview versions the Webhook expects. API server will try to use first version in the list which it supports. If none of the versions specified in this list supported by API server, validation will fail for this object. If a persisted webhook configuration specifies allowed versions and does not include any versions known to the API Server, calls to the webhook will fail and be subject to the failure policy.

- **webhooks.clientConfig** (WebhookClientConfig), required

ClientConfig defines how to communicate with the hook. Required

*WebhookClientConfig contains the information to make a TLS connection with the webhook*

- **webhooks.clientConfig.caBundle** ([]byte)

caBundle is a PEM encoded CA bundle which will be used to validate the webhook's server certificate. If unspecified, system trust roots on the apiserver are used.

- **webhooks.clientConfig.service** (ServiceReference)

service is a reference to the service for this webhook. Either service or url must be specified.

If the webhook is running within the cluster, then you should use service.

*ServiceReference holds a reference to Service.legacy.k8s.io*

- **webhooks.clientConfig.service.name** (string), required

name is the name of the service. Required

- **webhooks.clientConfig.service.namespace** (string), required

namespace is the namespace of the service. Required

- **webhooks.clientConfig.service.path** (string)

path is an optional URL path which will be sent in any request to this service.

- **webhooks.clientConfig.service.port** (int32)

If specified, the port on the service that hosting webhook. Default to 443 for backward compatibility. port should be a valid port number (1-65535, inclusive).

- **webhooks.clientConfig.url** (string)

url gives the location of the webhook, in standard URL form (scheme://host:port/path). Exactly one of url or service must be specified.

The host should not refer to a service running in the cluster; use the service field instead. The host might be resolved via external DNS in some apiservers (e.g., kube-apiserver cannot resolve in-cluster DNS as that would be a layering violation). host may also be an IP address.

Please note that using localhost or 127.0.0.1 as a host is risky unless you take great care to run this webhook on all hosts which run an apiserver which might need to make calls to this webhook. Such installs are likely to be non-portable, i.e., not easy to turn up in a new cluster.

The scheme must be "https"; the URL must begin with "https://".

A path is optional, and if present may be any string permissible in a URL. You may use the path to pass an arbitrary string to the webhook, for example, a cluster identifier.

Attempting to use a user or basic auth e.g. "user:password@" is not allowed. Fragments ("#...") and query parameters ("?...") are not allowed, either.

- **webhooks.name** (string), required

The name of the admission webhook. Name should be fully qualified, e.g., imagepolicy.kubernetes.io, where "imagepolicy" is the name of the webhook, and kubernetes.io is the name of the organization. Required.

- **webhooks.sideEffects** (string), required

SideEffects states whether this webhook has side effects. Acceptable values are: None, NoneOnDryRun (webhooks created via v1beta1 may also specify Some or

Unknown). Webhooks with side effects MUST implement a reconciliation system, since a request may be rejected by a future step in the admission chain and the side effects therefore need to be undone. Requests with the dryRun attribute will be auto-rejected if they match a webhook with sideEffects == Unknown or Some.

- **webhooks.failurePolicy** (string)

FailurePolicy defines how unrecognized errors from the admission endpoint are handled - allowed values are Ignore or Fail. Defaults to Fail.

- **webhooks.matchConditions** ([]MatchCondition)

*Patch strategy: merge on key name*

*Map: unique values on key name will be kept during a merge*

MatchConditions is a list of conditions that must be met for a request to be sent to this webhook. Match conditions filter requests that have already been matched by the rules, namespaceSelector, and objectSelector. An empty list of matchConditions matches all requests. There are a maximum of 64 match conditions allowed.

The exact matching logic is (in order):

1. If ANY matchCondition evaluates to FALSE, the webhook is skipped.
2. If ALL matchConditions evaluate to TRUE, the webhook is called.
3. If any matchCondition evaluates to an error (but none are FALSE):
  - If failurePolicy=Fail, reject the request
  - If failurePolicy=Ignore, the error is ignored and the webhook is skipped

This is a beta feature and managed by the AdmissionWebhookMatchConditions feature gate.

*MatchCondition represents a condition which must be fulfilled for a request to be sent to a webhook.*

- **webhooks.matchConditions.expression** (string), required

Expression represents the expression which will be evaluated by CEL. Must evaluate to bool. CEL expressions have access to the contents of the AdmissionRequest and Authorizer, organized into CEL variables:

'object' - The object from the incoming request. The value is null for DELETE requests. 'oldObject' - The existing object. The value is null for CREATE requests. 'request' - Attributes of the admission request (/pkg/apis/admission/types.go#AdmissionRequest). 'authorizer' - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See <https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz> 'authorizer.requestResource' - A CEL ResourceCheck constructed from the 'authorizer' and configured with the request resource. Documentation on CEL: <https://kubernetes.io/docs/reference/using-api/cel/>

Required.

- **webhooks.matchConditions.name** (string), required

Name is an identifier for this match condition, used for strategic merging of MatchConditions, as well as providing an identifier for logging purposes. A good name should be descriptive of the associated expression. Name must be a qualified name consisting of alphanumeric characters, '-', '.' or '\_', and must start and end with an alphanumeric character (e.g. 'MyName', or 'my.name', or '123-abc', regex used for validation is '([A-Za-z0-9](-|\.|\_)?[A-Za-z0-9])' with an optional DNS subdomain prefix and '/' (e.g. 'example.com/MyName')

Required.

- **webhooks.matchPolicy** (string)

matchPolicy defines how the "rules" list is used to match incoming requests. Allowed values are "Exact" or "Equivalent".

- **Exact:** match a request only if it exactly matches a specified rule. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, but "rules" only included apiGroups: ["apps"], apiVersions: ["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would not be sent to the webhook.
- **Equivalent:** match a request if modifies a resource listed in rules, even via another API group or version. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, and "rules" only included apiGroups: ["apps"], apiVersions: ["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would be converted to apps/v1 and sent to the webhook.

Defaults to "Equivalent"

- **webhooks.namespaceSelector** ([LabelSelector](#))

NamespaceSelector decides whether to run the webhook on an object based on whether the namespace for that object matches the selector. If the object itself is a namespace, the matching is performed on object.metadata.labels. If the object is another cluster scoped resource, it never skips the webhook.

For example, to run the webhook on any objects whose namespace is not associated with "runlevel" of "0" or "1"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "runlevel", "operator": "NotIn", "values": [ "0", "1" ] } ] }

If instead you want to only run the webhook on any objects whose namespace is associated with the "environment" of "prod" or "staging"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "environment", "operator": "In", "values": [ "prod", "staging" ] } ] }

See <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels> for more examples of label selectors.

Default to the empty LabelSelector, which matches everything.

- **webhooks.objectSelector** ([LabelSelector](#))

ObjectSelector decides whether to run the webhook based on if the object has matching labels. objectSelector is evaluated against both the oldObject and newObject that would be sent to the webhook, and is considered to match if either object matches the selector. A null object (oldObject in the case of create, or newObject in the case of delete) or an object that cannot have labels (like a DeploymentRollback or a PodProxyOptions object) is not considered to match. Use the object selector only if the webhook is opt-in, because end users may skip the admission webhook by setting the labels. Default to the empty LabelSelector, which matches everything.

- **webhooks.rules** ([]RuleWithOperations)

Rules describes what operations on what resources/subresources the webhook cares about. The webhook cares about an operation if it matches *any* Rule. However, in order to prevent ValidatingAdmissionWebhooks and MutatingAdmissionWebhooks from putting the cluster in a state which cannot be recovered from without completely disabling the plugin, ValidatingAdmissionWebhooks and MutatingAdmissionWebhooks are never called on admission requests for ValidatingWebhookConfiguration and MutatingWebhookConfiguration objects.

*RuleWithOperations is a tuple of Operations and Resources. It is recommended to make sure that all the tuple expansions are valid.*

- **webhooks.rules.apiGroups** ([]string)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

- **webhooks.rules.apiVersions** ([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

- **webhooks.rules.operations** ([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

- **webhooks.rules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources

of pods. *'/scale' means all scale subresources. '/' means all resources and their subresources.*

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed.  
Required.

- **webhooks.rules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" *"Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule. "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is "".*

- **webhooks.timeoutSeconds** (int32)

TimeoutSeconds specifies the timeout for this webhook. After the timeout passes, the webhook call will be ignored or the API call will fail based on the failure policy. The timeout value must be between 1 and 30 seconds. Default to 10 seconds.

## ValidatingWebhookConfigurationList

ValidatingWebhookConfigurationList is a list of ValidatingWebhookConfiguration.

---

- **apiVersion:** admissionregistration.k8s.io/v1

# ValidatingAdmissionPolicy v1beta1

ValidatingAdmissionPolicy describes the definition of an admission validation policy that accepts or rejects an object without changing it.

apiVersion: admissionregistration.k8s.io/v1beta1

import "k8s.io/api/admissionregistration/v1beta1"

## ValidatingAdmissionPolicy

ValidatingAdmissionPolicy describes the definition of an admission validation policy that accepts or rejects an object without changing it.

- 
- **apiVersion**: admissionregistration.k8s.io/v1beta1
  - **kind**: ValidatingAdmissionPolicy
  - **metadata** ([ObjectMeta](#))

Standard object metadata; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>.

- **spec** (ValidatingAdmissionPolicySpec)

Specification of the desired behavior of the ValidatingAdmissionPolicy.

*ValidatingAdmissionPolicySpec is the specification of the desired behavior of the AdmissionPolicy.*

- **spec.auditAnnotations** ([]AuditAnnotation)

*Atomic: will be replaced during a merge*

auditAnnotations contains CEL expressions which are used to produce audit annotations for the audit event of the API request. validations and auditAnnotations may not both be empty; a least one of validations or auditAnnotations is required.

*AuditAnnotation describes how to produce an audit annotation for an API request.*

- **spec.auditAnnotations.key** (string), required

key specifies the audit annotation key. The audit annotation keys of a ValidatingAdmissionPolicy must be unique. The key must be a qualified name ([A-Za-z0-9][-A-Za-z0-9\_.]\*) no more than 63 bytes in length.

The key is combined with the resource name of the ValidatingAdmissionPolicy to construct an audit annotation key: "{ValidatingAdmissionPolicy name}/{key}".

If an admission webhook uses the same resource name as this ValidatingAdmissionPolicy and the same audit annotation key, the annotation key will be identical. In this case, the first annotation written with the key will be included in the audit event and all subsequent annotations with the same key will be discarded.

Required.

- **spec.auditAnnotations.valueExpression** (string), required

valueExpression represents the expression which is evaluated by CEL to produce an audit annotation value. The expression must evaluate to either a string or null value. If the expression evaluates to a string, the audit annotation is included with the string value. If the expression evaluates to null or empty string the audit annotation will be omitted. The valueExpression may be no longer than 5kb in length. If the result of the valueExpression is more than 10kb in length, it will be truncated to 10kb.

If multiple ValidatingAdmissionPolicyBinding resources match an API request, then the valueExpression will be evaluated for each binding. All unique values produced by the valueExpressions will be joined together in a comma-separated list.

Required.

- **spec.failurePolicy** (string)

failurePolicy defines how to handle failures for the admission policy. Failures can occur from CEL expression parse errors, type check errors, runtime errors and invalid or mis-configured policy definitions or bindings.

A policy is invalid if `spec.paramKind` refers to a non-existent Kind. A binding is invalid if `spec.paramRef.name` refers to a non-existent resource.

`failurePolicy` does not define how validations that evaluate to false are handled.

When `failurePolicy` is set to Fail, `ValidatingAdmissionPolicyBinding` `validationActions` define how failures are enforced.

Allowed values are Ignore or Fail. Defaults to Fail.

- **`spec.matchConditions`** (`[]MatchCondition`)

*Patch strategy: merge on key name*

*Map: unique values on key name will be kept during a merge*

`MatchConditions` is a list of conditions that must be met for a request to be validated. Match conditions filter requests that have already been matched by the rules, `namespaceSelector`, and `objectSelector`. An empty list of `matchConditions` matches all requests. There are a maximum of 64 match conditions allowed.

If a parameter object is provided, it can be accessed via the `params` handle in the same manner as validation expressions.

The exact matching logic is (in order):

1. If ANY `matchCondition` evaluates to FALSE, the policy is skipped.
2. If ALL `matchConditions` evaluate to TRUE, the policy is evaluated.
3. If any `matchCondition` evaluates to an error (but none are FALSE):
  - If `failurePolicy=Fail`, reject the request
  - If `failurePolicy=Ignore`, the policy is skipped

*MatchCondition represents a condition which must be fulfilled for a request to be sent to a webhook.*

- **`spec.matchConditions.expression`** (string), required

Expression represents the expression which will be evaluated by CEL. Must evaluate to bool. CEL expressions have access to the contents of the `AdmissionRequest` and `Authorizer`, organized into CEL variables:

'object' - The object from the incoming request. The value is null for DELETE requests. 'oldObject' - The existing object. The value is null for CREATE requests. 'request' - Attributes of the admission request (`/pkg/apis/admission/types.go#AdmissionRequest`). 'authorizer' - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See <https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz> 'authorizer.requestResource' - A CEL ResourceCheck constructed from the 'authorizer' and configured with the request resource. Documentation on CEL: <https://kubernetes.io/docs/reference/using-api/cel/>

Required.

- **`spec.matchConditions.name`** (string), required

Name is an identifier for this match condition, used for strategic merging of MatchConditions, as well as providing an identifier for logging purposes. A good name should be descriptive of the associated expression. Name must be a qualified name consisting of alphanumeric characters, '-', '\_' or '.', and must start and end with an alphanumeric character (e.g. 'MyName', or 'my.name', or '123-abc', regex used for validation is '([A-Za-z0-9](-|\_|\.)\*)?[A-Za-z0-9]') with an optional DNS subdomain prefix and '/' (e.g. 'example.com/MyName')

Required.

- **spec.matchConstraints** (MatchResources)

MatchConstraints specifies what resources this policy is designed to validate. The AdmissionPolicy cares about a request if it matches *all* Constraints. However, in order to prevent clusters from being put into an unstable state that cannot be recovered from via the API ValidatingAdmissionPolicy cannot match ValidatingAdmissionPolicy and ValidatingAdmissionPolicyBinding. Required.

*MatchResources decides whether to run the admission control policy on an object based on whether it meets the match criteria. The exclude rules take precedence over include rules (if a resource matches both, it is excluded)*

- **spec.matchConstraints.excludeResourceRules**  
([]NamedRuleWithOperations)

*Atomic: will be replaced during a merge*

ExcludeResourceRules describes what operations on what resources/subresources the ValidatingAdmissionPolicy should not care about. The exclude rules take precedence over include rules (if a resource matches both, it is excluded)

*NamedRuleWithOperations is a tuple of Operations and Resources with ResourceNames.*

- **spec.matchConstraints.excludeResourceRules.apiGroups**  
([]string)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

- **spec.matchConstraints.excludeResourceRules.apiVersions**  
([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

- **spec.matchConstraints.excludeResourceRules.operations**  
([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

- **spec.matchConstraints.excludeResourceRules.resourceNames** ([]string)

*Atomic: will be replaced during a merge*

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

- **spec.matchConstraints.excludeResourceRules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources of pods. '/scale' means all scale subresources. '/' means all resources and their subresources.

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed. Required.

- **spec.matchConstraints.excludeResourceRules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" *"Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule. "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is ""*.

- **spec.matchConstraints.matchPolicy** (string)

matchPolicy defines how the "MatchResources" list is used to match incoming requests. Allowed values are "Exact" or "Equivalent".

- **Exact:** match a request only if it exactly matches a specified rule. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, but "rules" only included apiGroups:["apps"], apiVersions:["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would not be sent to the ValidatingAdmissionPolicy.
- **Equivalent:** match a request if modifies a resource listed in rules, even via another API group or version. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, and

"rules" only included `apiGroups:["apps"], apiVersions:["v1"], resources: ["deployments"],` a request to `apps/v1beta1` or `extensions/v1beta1` would be converted to `apps/v1` and sent to the `ValidatingAdmissionPolicy`.

Defaults to "Equivalent"

- **`spec.matchConstraints.namespaceSelector`** ([LabelSelector](#))

`NamespaceSelector` decides whether to run the admission control policy on an object based on whether the namespace for that object matches the selector. If the object itself is a namespace, the matching is performed on `object.metadata.labels`. If the object is another cluster scoped resource, it never skips the policy.

For example, to run the webhook on any objects whose namespace is not associated with "runlevel" of "0" or "1"; you will set the selector as follows: `"namespaceSelector": { "matchExpressions": [ { "key": "runlevel", "operator": "NotIn", "values": [ "0", "1" ] } ] }`

If instead you want to only run the policy on any objects whose namespace is associated with the "environment" of "prod" or "staging"; you will set the selector as follows: `"namespaceSelector": { "matchExpressions": [ { "key": "environment", "operator": "In", "values": [ "prod", "staging" ] } ] }`

See <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/> for more examples of label selectors.

Default to the empty `LabelSelector`, which matches everything.

- **`spec.matchConstraints.objectSelector`** ([LabelSelector](#))

`ObjectSelector` decides whether to run the validation based on if the object has matching labels. `objectSelector` is evaluated against both the `oldObject` and `newObject` that would be sent to the cel validation, and is considered to match if either object matches the selector. A null object (`oldObject` in the case of create, or `newObject` in the case of delete) or an object that cannot have labels (like a `DeploymentRollback` or a `PodProxyOptions` object) is not considered to match. Use the object selector only if the webhook is opt-in, because end users may skip the admission webhook by setting the labels. Default to the empty `LabelSelector`, which matches everything.

- **`spec.matchConstraints.resourceRules`** (`[]NamedRuleWithOperations`)

*Atomic: will be replaced during a merge*

`ResourceRules` describes what operations on what resources/subresources the `ValidatingAdmissionPolicy` matches. The policy cares about an operation if it matches *any* Rule.

*NamedRuleWithOperations is a tuple of Operations and Resources with ResourceNames.*

- **`spec.matchConstraints.resourceRules.apiGroups`** (`[]string`)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

▪ **spec.matchConstraints.resourceRules.apiVersions** ([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

▪ **spec.matchConstraints.resourceRules.operations** ([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

▪ **spec.matchConstraints.resourceRules.resourceNames** ([]string)

*Atomic: will be replaced during a merge*

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

▪ **spec.matchConstraints.resourceRules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources of pods. '/scale' means all scale subresources. '/' means all resources and their subresources.

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed. Required.

▪ **spec.matchConstraints.resourceRules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" "Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule. "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is "".

◦ **spec.paramKind** (ParamKind)

ParamKind specifies the kind of resources used to parameterize this policy. If absent, there are no parameters for this policy and the param CEL variable will not be provided to validation expressions. If ParamKind refers to a non-existent kind, this policy definition is mis-configured and the FailurePolicy is applied. If paramKind is specified but paramRef is unset in ValidatingAdmissionPolicyBinding, the params variable will be null.

*ParamKind is a tuple of Group Kind and Version.*

- **spec.paramKind.apiVersion** (string)

APIVersion is the API group version the resources belong to. In format of "group/version". Required.

- **spec.paramKind.kind** (string)

Kind is the API kind the resources belong to. Required.

- **spec.validations** ([]Validation)

*Atomic: will be replaced during a merge*

Validations contain CEL expressions which is used to apply the validation. Validations and AuditAnnotations may not both be empty; a minimum of one Validations or AuditAnnotations is required.

*Validation specifies the CEL expression which is used to apply the validation.*

- **spec.validations.expression** (string), required

Expression represents the expression which will be evaluated by CEL. ref: <https://github.com/google/cel-spec> CEL expressions have access to the contents of the API request/response, organized into CEL variables as well as some other useful variables:

- 'object' - The object from the incoming request. The value is null for DELETE requests. - 'oldObject' - The existing object. The value is null for CREATE requests. - 'request' - Attributes of the API request(ref). - 'params' - Parameter resource referred to by the policy binding being evaluated. Only populated if the policy has a ParamKind. - 'namespaceObject' - The namespace object that the incoming object belongs to. The value is null for cluster-scoped resources. - 'variables' - Map of composited variables, from its name to its lazily evaluated value. For example, a variable named 'foo' can be accessed as 'variables.foo'.
- 'authorizer' - A CEL Authorizer. May be used to perform authorization checks for the principal (user or service account) of the request. See <https://pkg.go.dev/k8s.io/apiserver/pkg/cel/library#Authz>
- 'authorizer.requestResource' - A CEL ResourceCheck constructed from the 'authorizer' and configured with the request resource.

The apiVersion, kind, metadata.name and metadata.generateName are always accessible from the root of the object. No other metadata properties are accessible.

Only property names of the form `[a-zA-Z_./][a-zA-Z0-9_./]*` are accessible. Accessible property names are escaped according to the following rules when accessed in the expression: - `"` escapes to `'underscores'` - `'` escapes to `'dot'` - `-` escapes to `'dash'` - `/` escapes to `'slash'` - **Property names that exactly match a CEL RESERVED keyword escape to `{keyword}__`**. The keywords are: `"true"`, `"false"`, `"null"`, `"in"`, `"as"`, `"break"`, `"const"`, `"continue"`, `"else"`, `"for"`, `"function"`, `"if"`, `"import"`, `"let"`, `"loop"`, `"package"`, `"namespace"`, `"return"`. Examples:

- Expression accessing a property named `"namespace"`: `{"Expression": "object.namespace > 0"}`
- Expression accessing a property named `"x-prop"`: `{"Expression": "object.x__dash__prop > 0"}`
- Expression accessing a property named `"redact__d"`: `{"Expression": "object.redact__underscores__d > 0"}`

Equality on arrays with list type of `'set'` or `'map'` ignores element order, i.e. `[1, 2] == [2, 1]`. Concatenation on arrays with `x-kubernetes-list-type` use the semantics of the list type:

- `'set'`: `X + Y` performs a union where the array positions of all elements in `X` are preserved and non-intersecting elements in `Y` are appended, retaining their partial order.
- `'map'`: `X + Y` performs a merge where the array positions of all keys in `X` are preserved but the values are overwritten by values in `Y` when the key sets of `X` and `Y` intersect. Elements in `Y` with non-intersecting keys are appended, retaining their partial order. Required.

- **`spec.validations.message`** (string)

Message represents the message displayed when validation fails. The message is required if the Expression contains line breaks. The message must not contain line breaks. If unset, the message is `"failed rule: {Rule}"`. e.g. `"must be a URL with the host matching spec.host"` If the Expression contains line breaks. Message is required. The message must not contain line breaks. If unset, the message is `"failed Expression: {Expression}"`.

- **`spec.validations.messageExpression`** (string)

`messageExpression` declares a CEL expression that evaluates to the validation failure message that is returned when this rule fails. Since `messageExpression` is used as a failure message, it must evaluate to a string. If both `message` and `messageExpression` are present on a validation, then `messageExpression` will be used if validation fails. If `messageExpression` results in a runtime error, the runtime error is logged, and the validation failure message is produced as if the `messageExpression` field were unset. If `messageExpression` evaluates to an empty string, a string with only spaces, or a string that contains line breaks, then the validation failure message will also be produced as if the `messageExpression` field were unset, and the fact that `messageExpression` produced an empty string/string with only spaces/string with line breaks will be logged. `messageExpression` has access to all the same variables as the expression except for `'authorizer'` and `'authorizer.requestResource'`. Example: `"object.x must be less than max (" + string(params.max) + ")"`

- **spec.validations.reason** (string)

Reason represents a machine-readable description of why this validation failed. If this is the first validation in the list to fail, this reason, as well as the corresponding HTTP response code, are used in the HTTP response to the client. The currently supported reasons are: "Unauthorized", "Forbidden", "Invalid", "RequestEntityTooLarge". If not set, StatusReasonInvalid is used in the response to the client.

- **spec.variables** ([]Variable)

*Patch strategy: merge on key name*

*Map: unique values on key name will be kept during a merge*

Variables contain definitions of variables that can be used in composition of other expressions. Each variable is defined as a named CEL expression. The variables defined here will be available under variables in other expressions of the policy except MatchConditions because MatchConditions are evaluated before the rest of the policy.

The expression of a variable can refer to other variables defined earlier in the list but not those after. Thus, Variables must be sorted by the order of first appearance and acyclic.

*Variable is the definition of a variable that is used for composition. A variable is defined as a named expression.*

- **spec.variables.expression** (string), required

Expression is the expression that will be evaluated as the value of the variable. The CEL expression has access to the same identifiers as the CEL expressions in Validation.

- **spec.variables.name** (string), required

Name is the name of the variable. The name must be a valid CEL identifier and unique among all variables. The variable can be accessed in other expressions through variables. For example, if name is "foo", the variable will be available as variables.foo

- **status** (ValidatingAdmissionPolicyStatus)

The status of the ValidatingAdmissionPolicy, including warnings that are useful to determine if the policy behaves in the expected way. Populated by the system. Read-only.

*ValidatingAdmissionPolicyStatus represents the status of an admission validation policy.*

- **status.conditions** ([]Condition)

*Map: unique values on key type will be kept during a merge*

The conditions represent the latest available observations of a policy's current state.

*Condition contains details for one aspect of the current state of this API Resource.*

- **status.conditions.lastTransitionTime** (Time), required

lastTransitionTime is the last time the condition transitioned from one status to another. This should be when the underlying condition changed. If that is not known, then using the time when the API field changed is acceptable.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **status.conditions.message** (string), required

message is a human readable message indicating details about the transition. This may be an empty string.

- **status.conditions.reason** (string), required

reason contains a programmatic identifier indicating the reason for the condition's last transition. Producers of specific condition types may define expected values and meanings for this field, and whether the values are considered a guaranteed API. The value should be a CamelCase string. This field may not be empty.

- **status.conditions.status** (string), required

status of the condition, one of True, False, Unknown.

- **status.conditions.type** (string), required

type of condition in CamelCase or in foo.example.com/CamelCase.

- **status.conditions.observedGeneration** (int64)

observedGeneration represents the .metadata.generation that the condition was set based upon. For instance, if .metadata.generation is currently 12, but the .status.conditions[x].observedGeneration is 9, the condition is out of date with respect to the current state of the instance.

- **status.observedGeneration** (int64)

The generation observed by the controller.

- **status.typeChecking** (TypeChecking)

The results of type checking for each expression. Presence of this field indicates the completion of the type checking.

*TypeChecking contains results of type checking the expressions in the ValidatingAdmissionPolicy*

- **status.typeChecking.expressionWarnings** ([]ExpressionWarning)

*Atomic: will be replaced during a merge*

The type checking warnings for each expression.

*ExpressionWarning* is a warning information that targets a specific expression.

- **status.typeChecking.expressionWarnings.fieldRef** (string), required

The path to the field that refers the expression. For example, the reference to the expression of the first item of validations is "spec.validations[0].expression"

- **status.typeChecking.expressionWarnings.warning** (string), required

The content of type checking information in a human-readable form. Each line of the warning contains the type that the expression is checked against, followed by the type check error from the compiler.

## ValidatingAdmissionPolicyList

ValidatingAdmissionPolicyList is a list of ValidatingAdmissionPolicy.

---

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **items** ([\[\]ValidatingAdmissionPolicy](#))

List of ValidatingAdmissionPolicy.

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

## ValidatingAdmissionPolicyBinding

ValidatingAdmissionPolicyBinding binds the ValidatingAdmissionPolicy with parameterized resources. ValidatingAdmissionPolicyBinding and parameter CRDs together define how cluster administrators configure policies for clusters.

For a given admission request, each binding will cause its policy to be evaluated N times, where N is 1 for policies/bindings that don't use params, otherwise N is the number of parameters selected by the binding.

The CEL expressions of a policy must have a computed CEL cost below the maximum CEL budget. Each evaluation of the policy is given an independent CEL cost budget. Adding/removing policies, bindings, or params can not affect whether a given (policy, binding, param) combination is within its own CEL budget.

---

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **metadata** ([ObjectMeta](#))

Standard object metadata; More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>.

- **spec** ([ValidatingAdmissionPolicyBindingSpec](#))

Specification of the desired behavior of the [ValidatingAdmissionPolicyBinding](#).

*[ValidatingAdmissionPolicyBindingSpec](#) is the specification of the [ValidatingAdmissionPolicyBinding](#).*

- **spec.matchResources** ([MatchResources](#))

[MatchResources](#) declares what resources match this binding and will be validated by it. Note that this is intersected with the policy's [matchConstraints](#), so only requests that are matched by the policy can be selected by this. If this is unset, all resources matched by the policy are validated by this binding. When [resourceRules](#) is unset, it does not constrain resource matching. If a resource is matched by the other fields of this object, it will be validated. Note that this differs from [ValidatingAdmissionPolicy matchConstraints](#), where [resourceRules](#) are required.

*[MatchResources](#) decides whether to run the admission control policy on an object based on whether it meets the match criteria. The exclude rules take precedence over include rules (if a resource matches both, it is excluded)*

- **spec.matchResources.excludeResourceRules**  
([\[\]NamedRuleWithOperations](#))

*Atomic: will be replaced during a merge*

ExcludeResourceRules describes what operations on what resources/subresources the ValidatingAdmissionPolicy should not care about. The exclude rules take precedence over include rules (if a resource matches both, it is excluded)

*NamedRuleWithOperations is a tuple of Operations and Resources with ResourceNames.*

- **spec.matchResources.excludeResourceRules.apiGroups** ([]string)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

- **spec.matchResources.excludeResourceRules.apiVersions** ([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

- **spec.matchResources.excludeResourceRules.operations** ([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

- **spec.matchResources.excludeResourceRules.resourceNames** ([]string)

*Atomic: will be replaced during a merge*

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

- **spec.matchResources.excludeResourceRules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources of pods. '/scale' means all scale subresources. '/' means all resources and their subresources.

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed. Required.

- **spec.matchResources.excludeResourceRules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" *"Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule.* "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is "".

- **spec.matchResources.matchPolicy** (string)

matchPolicy defines how the "MatchResources" list is used to match incoming requests. Allowed values are "Exact" or "Equivalent".

- **Exact:** match a request only if it exactly matches a specified rule. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, but "rules" only included apiGroups:["apps"], apiVersions:["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would not be sent to the ValidatingAdmissionPolicy.
- **Equivalent:** match a request if modifies a resource listed in rules, even via another API group or version. For example, if deployments can be modified via apps/v1, apps/v1beta1, and extensions/v1beta1, and "rules" only included apiGroups:["apps"], apiVersions:["v1"], resources: ["deployments"], a request to apps/v1beta1 or extensions/v1beta1 would be converted to apps/v1 and sent to the ValidatingAdmissionPolicy.

Defaults to "Equivalent"

- **spec.matchResources.namespaceSelector** ([LabelSelector](#))

NamespaceSelector decides whether to run the admission control policy on an object based on whether the namespace for that object matches the selector. If the object itself is a namespace, the matching is performed on object.metadata.labels. If the object is another cluster scoped resource, it never skips the policy.

For example, to run the webhook on any objects whose namespace is not associated with "runlevel" of "0" or "1"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "runlevel", "operator": "NotIn", "values": [ "0", "1" ] } ] }

If instead you want to only run the policy on any objects whose namespace is associated with the "environment" of "prod" or "staging"; you will set the selector as follows: "namespaceSelector": { "matchExpressions": [ { "key": "environment", "operator": "In", "values": [ "prod", "staging" ] } ] }

See <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/> for more examples of label selectors.

Default to the empty LabelSelector, which matches everything.

- **spec.matchResources.objectSelector** ([LabelSelector](#))

ObjectSelector decides whether to run the validation based on if the object has matching labels. objectSelector is evaluated against both the oldObject and newObject that would be sent to the cel validation, and is considered to match if either object matches the selector. A null object (oldObject in the case of create, or newObject in the case of delete) or an object that cannot have labels (like a DeploymentRollback or a PodProxyOptions object) is not considered to match. Use the object selector only if the webhook is opt-in, because end users may skip the admission webhook by setting the labels. Default to the empty LabelSelector, which matches everything.

- **spec.matchResources.resourceRules** ([]NamedRuleWithOperations)

*Atomic: will be replaced during a merge*

ResourceRules describes what operations on what resources/subresources the ValidatingAdmissionPolicy matches. The policy cares about an operation if it matches *any* Rule.

*NamedRuleWithOperations is a tuple of Operations and Resources with ResourceNames.*

- **spec.matchResources.resourceRules.apiGroups** ([]string)

*Atomic: will be replaced during a merge*

APIGroups is the API groups the resources belong to. '' is all groups. If '' is present, the length of the slice must be one. Required.

- **spec.matchResources.resourceRules.apiVersions** ([]string)

*Atomic: will be replaced during a merge*

APIVersions is the API versions the resources belong to. '' is all versions. If '' is present, the length of the slice must be one. Required.

- **spec.matchResources.resourceRules.operations** ([]string)

*Atomic: will be replaced during a merge*

Operations is the operations the admission hook cares about - CREATE, UPDATE, DELETE, CONNECT or \* for all of those operations and any future admission operations that are added. If '\*' is present, the length of the slice must be one. Required.

- **spec.matchResources.resourceRules.resourceNames** ([]string)

*Atomic: will be replaced during a merge*

ResourceNames is an optional white list of names that the rule applies to. An empty set means that everything is allowed.

▪ **spec.matchResources.resourceRules.resources** ([]string)

*Atomic: will be replaced during a merge*

Resources is a list of resources this rule applies to.

For example: 'pods' means pods. 'pods/log' means the log subresource of pods. '' means all resources, but not subresources. 'pods/' means all subresources of pods. '/scale' means all scale subresources. '/' means all resources and their subresources.

If wildcard is present, the validation rule will ensure resources do not overlap with each other.

Depending on the enclosing object, subresources might not be allowed. Required.

▪ **spec.matchResources.resourceRules.scope** (string)

scope specifies the scope of this rule. Valid values are "Cluster", "Namespaced", and "" *"Cluster" means that only cluster-scoped resources will match this rule. Namespace API objects are cluster-scoped. "Namespaced" means that only namespaced resources will match this rule. "" means that there are no scope restrictions. Subresources match the scope of their parent resource. Default is "".*

◦ **spec.paramRef** (ParamRef)

paramRef specifies the parameter resource used to configure the admission control policy. It should point to a resource of the type specified in ParamKind of the bound ValidatingAdmissionPolicy. If the policy specifies a ParamKind and the resource referred to by ParamRef does not exist, this binding is considered mis-configured and the FailurePolicy of the ValidatingAdmissionPolicy applied. If the policy does not specify a ParamKind then this field is ignored, and the rules are evaluated without a param.

*ParamRef describes how to locate the params to be used as input to expressions of rules applied by a policy binding.*

▪ **spec.paramRef.name** (string)

name is the name of the resource being referenced.

One of name or selector must be set, but name and selector are mutually exclusive properties. If one is set, the other must be unset.

A single parameter used for all admission requests can be configured by setting the name field, leaving selector blank, and setting namespace if paramKind is namespace-scoped.

▪ **spec.paramRef.namespace** (string)

namespace is the namespace of the referenced resource. Allows limiting the search for params to a specific namespace. Applies to both name and selector fields.

A per-namespace parameter may be used by specifying a namespace-scoped paramKind in the policy and leaving this field empty.

- If paramKind is cluster-scoped, this field MUST be unset. Setting this field results in a configuration error.
- If paramKind is namespace-scoped, the namespace of the object being evaluated for admission will be used when this field is left unset. Take care that if this is left empty the binding must not match any cluster-scoped resources, which will result in an error.

▪ **spec.paramRef.parameterNotFoundAction** (string)

parameterNotFoundAction controls the behavior of the binding when the resource exists, and name or selector is valid, but there are no parameters matched by the binding. If the value is set to Allow, then no matched parameters will be treated as successful validation by the binding. If set to Deny, then no matched parameters will be subject to the failurePolicy of the policy.

Allowed values are Allow or Deny

Required

▪ **spec.paramRef.selector** ([LabelSelector](#))

selector can be used to match multiple param objects based on their labels. Supply selector: {} to match all resources of the ParamKind.

If multiple params are found, they are all evaluated with the policy expressions and the results are ANDed together.

One of name or selector must be set, but name and selector are mutually exclusive properties. If one is set, the other must be unset.

◦ **spec.policyName** (string)

PolicyName references a ValidatingAdmissionPolicy name which the ValidatingAdmissionPolicyBinding binds to. If the referenced resource does not exist, this binding is considered invalid and will be ignored Required.

◦ **spec.validationActions** ([]string)

*Set: unique values will be kept during a merge*

validationActions declares how Validations of the referenced ValidatingAdmissionPolicy are enforced. If a validation evaluates to false it is always enforced according to these actions.

Failures defined by the ValidatingAdmissionPolicy's FailurePolicy are enforced according to these actions only if the FailurePolicy is set to Fail, otherwise the failures are ignored. This includes compilation errors, runtime errors and misconfigurations of the policy.

validationActions is declared as a set of action values. Order does not matter. validationActions may not contain duplicates of the same action.

The supported actions values are:

"Deny" specifies that a validation failure results in a denied request.

"Warn" specifies that a validation failure is reported to the request client in HTTP Warning headers, with a warning code of 299. Warnings can be sent both for allowed or denied admission responses.

"Audit" specifies that a validation failure is included in the published audit event for the request. The audit event will contain a validation.policy.admission.k8s.io/validation\_failure audit annotation with a value containing the details of the validation failures, formatted as a JSON list of objects, each with the following fields: - message: The validation failure message string - policy: The resource name of the ValidatingAdmissionPolicy - binding: The resource name of the ValidatingAdmissionPolicyBinding - expressionIndex: The index of the failed validations in the ValidatingAdmissionPolicy - validationActions: The enforcement actions enacted for the validation failure Example audit annotation:

```
"validation.policy.admission.k8s.io/validation_failure": "[{"message": "Invalid value",
{"policy": "policy.example.com", {"binding": "policybinding.example.com",
{"expressionIndex": "1", {"validationActions": ["Audit"]}]"]"
```

Clients should expect to handle additional values by ignoring any values not recognized.

"Deny" and "Warn" may not be used together since this combination needlessly duplicates the validation failure both in the API response body and the HTTP warning headers.

Required.

## Operations

---

### get read the specified ValidatingAdmissionPolicy

#### HTTP Request

GET /apis/admissionregistration.k8s.io/v1beta1/validatingadmissionpolicies/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the ValidatingAdmissionPolicy
- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([ValidatingAdmissionPolicy](#)): OK

401: Unauthorized

## get read status of the specified ValidatingAdmissionPolicy

### HTTP Request

GET /apis/admissionregistration.k8s.io/v1beta1/validatingadmissionpolicies/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the ValidatingAdmissionPolicy
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([ValidatingAdmissionPolicy](#)): OK

401: Unauthorized

## list list or watch objects of kind ValidatingAdmissionPolicy

### HTTP Request

GET /apis/admissionregistration.k8s.io/v1beta1/validatingadmissionpolicies

### Parameters

- **allowWatchBookmarks** (*in query*): boolean  
[allowWatchBookmarks](#)
- **continue** (*in query*): string  
[continue](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)

- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)
- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean  
[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)
- **watch** (*in query*): boolean  
[watch](#)

## Response

200 ([ValidatingAdmissionPolicyList](#)): OK

401: Unauthorized

## create create a ValidatingAdmissionPolicy

### HTTP Request

POST /apis/admissionregistration.k8s.io/v1beta1/validatingadmissionpolicies

### Parameters

- **body**: [ValidatingAdmissionPolicy](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string

[fieldValidation](#)

- **pretty** (*in query*): string

[pretty](#)

## Response

200 ([ValidatingAdmissionPolicy](#)): OK

201 ([ValidatingAdmissionPolicy](#)): Created

202 ([ValidatingAdmissionPolicy](#)): Accepted

401: Unauthorized

## update replace the specified ValidatingAdmissionPolicy

### HTTP Request

PUT /apis/admissionregistration.k8s.io/v1beta1/validatingadmissionpolicies/{name}

### Parameters

- **name** (*in path*): string, required  
name of the ValidatingAdmissionPolicy
- **body**: [ValidatingAdmissionPolicy](#), required
- **dryRun** (*in query*): string

[dryRun](#)

- **fieldManager** (*in query*): string

401: Unauthorized

# Cluster Resources

---

## [Node](#)

Node is a worker node in Kubernetes.

## [Namespace](#)

Namespace provides a scope for Names.

## [Event](#)

Event is a report of an event somewhere in the cluster.

## [APIService](#)

APIService represents a server for a particular GroupVersion.

## [Lease](#)

Lease defines a lease concept.

## [RuntimeClass](#)

RuntimeClass defines a class of container runtime supported in the cluster.

## [FlowSchema v1beta3](#)

FlowSchema defines the schema of a group of flows.

## [PriorityLevelConfiguration v1beta3](#)

PriorityLevelConfiguration represents the configuration of a priority level.

## [Binding](#)

Binding ties one object to another; for example, a pod is bound to a node by a scheduler.

## [ComponentStatus](#)

ComponentStatus (and ComponentStatusList) holds the cluster validation info.

## [ClusterCIDR v1alpha1](#)

ClusterCIDR represents a single configuration for per-Node Pod CIDR allocations when the MultiCIDRRangeAllocator is enabled (see the config for kube-controller-manager).

# Node

Node is a worker node in Kubernetes.

apiVersion: v1

```
import "k8s.io/api/core/v1"
```

# Node

Node is a worker node in Kubernetes. Each node will have a unique identifier in the cache (i.e. in etcd).

- 
- **apiVersion:** v1
  - **kind:** Node
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([NodeSpec](#))

Spec defines the behavior of a node. <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([NodeStatus](#))

Most recently observed status of the node. Populated by the system. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

# NodeSpec

NodeSpec describes the attributes that a node is created with.

- 
- **configSource** (NodeConfigSource)

Deprecated: Previously used to specify the source of the node's configuration for the DynamicKubeletConfig feature. This feature is removed.

*NodeConfigSource specifies a source of node configuration. Exactly one subfield (excluding metadata) must be non-nil. This API is deprecated since 1.22*

- **configSource.configMap** (ConfigMapNodeConfigSource)

ConfigMap is a reference to a Node's ConfigMap

*ConfigMapNodeConfigSource contains the information to reference a ConfigMap as a config source for the Node. This API is deprecated since 1.22: <https://git.k8s.io/enhancements/keps/sig-node/281-dynamic-kubelet-configuration>*

- **configSource.configMap.kubeletConfigKey** (string), required

KubeletConfigKey declares which key of the referenced ConfigMap corresponds to the KubeletConfiguration structure. This field is required in all cases.

- **configSource.configMap.name** (string), required

Name is the metadata.name of the referenced ConfigMap. This field is required in all cases.

- **configSource.configMap.namespace** (string), required

Namespace is the metadata.namespace of the referenced ConfigMap. This field is required in all cases.

- **configSource.configMap.resourceVersion** (string)

ResourceVersion is the metadata.ResourceVersion of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

- **configSource.configMap.uid** (string)

UID is the metadata.UID of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

- **externalID** (string)

Deprecated. Not all kubelets will set this field. Remove field after 1.13. see: <https://issues.k8s.io/61966>

- **podCIDR** (string)

PodCIDR represents the pod IP range assigned to the node.

- **podCIDRs** ([]string)

podCIDRs represents the IP ranges assigned to the node for usage by Pods on that node. If this field is specified, the 0th entry must match the podCIDR field. It may contain at most 1 value for each of IPv4 and IPv6.

- **providerID** (string)

ID of the node assigned by the cloud provider in the format: <ProviderName>://<ProviderSpecificNodeID>

- **taints** ([]Taint)

If specified, the node's taints.

*The node this Taint is attached to has the "effect" on any pod that does not tolerate the Taint.*

- **taints.effect** (string), required

Required. The effect of the taint on pods that do not tolerate the taint. Valid effects are NoSchedule, PreferNoSchedule and NoExecute.

- **taints.key** (string), required

Required. The taint key to be applied to a node.

- **taints.timeAdded** (Time)

TimeAdded represents the time at which the taint was added. It is only written for NoExecute taints.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **taints.value** (string)

The taint value corresponding to the taint key.

- **unschedulable** (boolean)

Unschedulable controls node schedulability of new pods. By default, node is schedulable. More info: <https://kubernetes.io/docs/concepts/nodes/node/#manual-node-administration>

## NodeStatus

NodeStatus is information about the current status of a node.

---

- **addresses** ([]NodeAddress)

*Patch strategy: merge on key type*

List of addresses reachable to the node. Queried from cloud provider, if available. More info: <https://kubernetes.io/docs/concepts/nodes/node/#addresses> Note: This field is declared as mergeable, but the merge key is not sufficiently unique, which can cause data corruption when it is merged. Callers should instead use a full-replacement patch. See <https://pr.k8s.io/79391> for an example. Consumers should assume that addresses can change during the lifetime of a Node. However, there are some exceptions where this

may not be possible, such as Pods that inherit a Node's address in its own status or consumers of the downward API (status.hostIP).

*NodeAddress contains information for the node's address.*

- **addresses.address** (string), required

The node address.

- **addresses.type** (string), required

Node address type, one of Hostname, ExternalIP or InternalIP.

- **allocatable** (map[string][Quantity](#))

Allocatable represents the resources of a node that are available for scheduling. Defaults to Capacity.

- **capacity** (map[string][Quantity](#))

Capacity represents the total resources of a node. More info: <https://kubernetes.io/docs/concepts/storage/persistent-volumes#capacity>

- **conditions** ([]NodeCondition)

*Patch strategy: merge on key type*

Conditions is an array of current observed node conditions. More info: <https://kubernetes.io/docs/concepts/nodes/node/#condition>

*NodeCondition contains condition information for a node.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of node condition.

- **conditions.lastHeartbeatTime** (Time)

Last time we got an update on a given condition.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.lastTransitionTime** (Time)

Last time the condition transit from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)
  - Human readable message indicating details about last transition.
- **conditions.reason** (string)
  - (brief) reason for the condition's last transition.
- **config** (NodeConfigStatus)
 

Status of the config assigned to the node via the dynamic Kubelet config feature.

*NodeConfigStatus describes the status of the config assigned by Node.Spec.ConfigSource.*

  - **config.active** (NodeConfigSource)
 

Active reports the checkpointed config the node is actively using. Active will represent either the current version of the Assigned config, or the current LastKnownGood config, depending on whether attempting to use the Assigned config results in an error.

*NodeConfigSource specifies a source of node configuration. Exactly one subfield (excluding metadata) must be non-nil. This API is deprecated since 1.22*

    - **config.active.configMap** (ConfigMapNodeConfigSource)
 

ConfigMap is a reference to a Node's ConfigMap

*ConfigMapNodeConfigSource contains the information to reference a ConfigMap as a config source for the Node. This API is deprecated since 1.22: <https://git.k8s.io/enhancements/keps/sig-node/281-dynamic-kubelet-configuration>*

      - **config.active.configMap.kubeletConfigKey** (string), required
 

KubeletConfigKey declares which key of the referenced ConfigMap corresponds to the KubeletConfiguration structure This field is required in all cases.
      - **config.active.configMap.name** (string), required
 

Name is the metadata.name of the referenced ConfigMap. This field is required in all cases.
      - **config.active.configMap.namespace** (string), required
 

Namespace is the metadata.namespace of the referenced ConfigMap. This field is required in all cases.
      - **config.active.configMap.resourceVersion** (string)
 

ResourceVersion is the metadata.ResourceVersion of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

▪ **config.active.configMap.uid** (string)

UID is the metadata.UID of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

◦ **config.assigned** (NodeConfigSource)

Assigned reports the checkpointed config the node will try to use. When Node.Spec.ConfigSource is updated, the node checkpoints the associated config payload to local disk, along with a record indicating intended config. The node refers to this record to choose its config checkpoint, and reports this record in Assigned. Assigned only updates in the status after the record has been checkpointed to disk. When the Kubelet is restarted, it tries to make the Assigned config the Active config by loading and validating the checkpointed payload identified by Assigned.

*NodeConfigSource specifies a source of node configuration. Exactly one subfield (excluding metadata) must be non-nil. This API is deprecated since 1.22*

▪ **config.assigned.configMap** (ConfigMapNodeConfigSource)

ConfigMap is a reference to a Node's ConfigMap

*ConfigMapNodeConfigSource contains the information to reference a ConfigMap as a config source for the Node. This API is deprecated since 1.22: <https://git.k8s.io/enhancements/keps/sig-node/281-dynamic-kubelet-configuration>*

▪ **config.assigned.configMap.kubeletConfigKey** (string), required

KubeletConfigKey declares which key of the referenced ConfigMap corresponds to the KubeletConfiguration structure. This field is required in all cases.

▪ **config.assigned.configMap.name** (string), required

Name is the metadata.name of the referenced ConfigMap. This field is required in all cases.

▪ **config.assigned.configMap.namespace** (string), required

Namespace is the metadata.namespace of the referenced ConfigMap. This field is required in all cases.

▪ **config.assigned.configMap.resourceVersion** (string)

ResourceVersion is the metadata.ResourceVersion of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

▪ **config.assigned.configMap.uid** (string)

UID is the metadata.UID of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

**config.error** (string)

◦

Error describes any problems reconciling the Spec.ConfigSource to the Active config. Errors may occur, for example, attempting to checkpoint Spec.ConfigSource to the local Assigned record, attempting to checkpoint the payload associated with Spec.ConfigSource, attempting to load or validate the Assigned config, etc. Errors may occur at different points while syncing config. Earlier errors (e.g. download or checkpointing errors) will not result in a rollback to LastKnownGood, and may resolve across Kubelet retries. Later errors (e.g. loading or validating a checkpointed config) will result in a rollback to LastKnownGood. In the latter case, it is usually possible to resolve the error by fixing the config assigned in Spec.ConfigSource. You can find additional information for debugging by searching the error message in the Kubelet log. Error is a human-readable description of the error state; machines can check whether or not Error is empty, but should not rely on the stability of the Error text across Kubelet versions.

◦ **config.lastKnownGood** (NodeConfigSource)

LastKnownGood reports the checkpointed config the node will fall back to when it encounters an error attempting to use the Assigned config. The Assigned config becomes the LastKnownGood config when the node determines that the Assigned config is stable and correct. This is currently implemented as a 10-minute soak period starting when the local record of Assigned config is updated. If the Assigned config is Active at the end of this period, it becomes the LastKnownGood. Note that if Spec.ConfigSource is reset to nil (use local defaults), the LastKnownGood is also immediately reset to nil, because the local default config is always assumed good. You should not make assumptions about the node's method of determining config stability and correctness, as this may change or become configurable in the future.

*NodeConfigSource specifies a source of node configuration. Exactly one subfield (excluding metadata) must be non-nil. This API is deprecated since 1.22*

▪ **config.lastKnownGood.configMap** (ConfigMapNodeConfigSource)

ConfigMap is a reference to a Node's ConfigMap

*ConfigMapNodeConfigSource contains the information to reference a ConfigMap as a config source for the Node. This API is deprecated since 1.22: <https://git.k8s.io/enhancements/keps/sig-node/281-dynamic-kubelet-configuration>*

▪ **config.lastKnownGood.configMap.kubeletConfigKey** (string), required

KubeletConfigKey declares which key of the referenced ConfigMap corresponds to the KubeletConfiguration structure. This field is required in all cases.

▪ **config.lastKnownGood.configMap.name** (string), required

Name is the metadata.name of the referenced ConfigMap. This field is required in all cases.

▪ **config.lastKnownGood.configMap.namespace** (string), required

Namespace is the metadata.namespace of the referenced ConfigMap. This field is required in all cases.

- **config.lastKnownGood.configMap.resourceVersion** (string)

ResourceVersion is the metadata.ResourceVersion of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

- **config.lastKnownGood.configMap.uid** (string)

UID is the metadata.UID of the referenced ConfigMap. This field is forbidden in Node.Spec, and required in Node.Status.

- **daemonEndpoints** (NodeDaemonEndpoints)

Endpoints of daemons running on the Node.

*NodeDaemonEndpoints lists ports opened by daemons running on the Node.*

- **daemonEndpoints.kubeletEndpoint** (DaemonEndpoint)

Endpoint on which Kubelet is listening.

*DaemonEndpoint contains information about a single Daemon endpoint.*

- **daemonEndpoints.kubeletEndpoint.Port** (int32), required

Port number of the given endpoint.

- **images** ([]ContainerImage)

List of container images on this node

*Describe a container image*

- **images.names** ([]string)

Names by which this image is known. e.g. ["kubernetes.example/hyperkube:v1.0.7", "cloud-vendor.registry.example/cloud-vendor/hyperkube:v1.0.7"]

- **images.sizeBytes** (int64)

The size of the image in bytes.

- **nodeInfo** (NodeSystemInfo)

Set of ids/uuids to uniquely identify the node. More info: <https://kubernetes.io/docs/concepts/nodes/node/#info>

*NodeSystemInfo is a set of ids/uuids to uniquely identify the node.*

- **nodeInfo.architecture** (string), required

The Architecture reported by the node

- **nodeInfo.bootID** (string), required
  - Boot ID reported by the node.
- **nodeInfo.containerRuntimeVersion** (string), required
  - ContainerRuntime Version reported by the node through runtime remote API (e.g. containerd://1.4.2).
- **nodeInfo.kernelVersion** (string), required
  - Kernel Version reported by the node from 'uname -r' (e.g. 3.16.0-0.bpo.4-amd64).
- **nodeInfo.kubeProxyVersion** (string), required
  - KubeProxy Version reported by the node.
- **nodeInfo.kubeletVersion** (string), required
  - Kubelet Version reported by the node.
- **nodeInfo.machineID** (string), required
  - MachineID reported by the node. For unique machine identification in the cluster this field is preferred. Learn more from man(5) machine-id: <http://man7.org/linux/man-pages/man5/machine-id.5.html>
- **nodeInfo.operatingSystem** (string), required
  - The Operating System reported by the node
- **nodeInfo.osImage** (string), required
  - OS Image reported by the node from /etc/os-release (e.g. Debian GNU/Linux 7 (wheezy)).
- **nodeInfo.systemUUID** (string), required
  - SystemUUID reported by the node. For unique machine identification MachineID is preferred. This field is specific to Red Hat hosts [https://access.redhat.com/documentation/en-us/red\\_hat\\_subscription\\_management/1/html/rhsm/uuid](https://access.redhat.com/documentation/en-us/red_hat_subscription_management/1/html/rhsm/uuid)
- **phase** (string)
  - NodePhase is the recently observed lifecycle phase of the node. More info: <https://kubernetes.io/docs/concepts/nodes/node/#phase> The field is never populated, and now is deprecated.
- **volumesAttached** ([]AttachedVolume)
  - List of volumes that are attached to the node.
  - *AttachedVolume describes a volume attached to a node*
  - **volumesAttached.devicePath** (string), required

DevicePath represents the device path where the volume should be available

- **volumesAttached.name** (string), required

Name of the attached volume

- **volumesInUse** ([]string)

List of attachable volumes in use (mounted) by the node.

## NodeList

NodeList is the whole list of all Nodes which have been registered with master.

---

- **apiVersion**: v1

- **kind**: NodeList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([][Node](#)), required

List of nodes

## Operations

---

### get read the specified Node

#### HTTP Request

GET /api/v1/nodes/{name}

#### Parameters

- **name** (*in path*): string, required

name of the Node

- **pretty** (*in query*): string

[pretty](#)

#### Response

200 ([Node](#)): OK

401: Unauthorized

## get read status of the specified Node

### HTTP Request

GET /api/v1/nodes/{name}/status

### Parameters

- **name** (*in path*): string, required

name of the Node

- **pretty** (*in query*): string

[pretty](#)

### Response

200 ([Node](#)): OK

401: Unauthorized

## list list or watch objects of kind Node

### HTTP Request

GET /api/v1/nodes

### Parameters

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

[fieldSelector](#)

- **labelSelector** (*in query*): string

[labelSelector](#)

- **limit** (*in query*): integer

# Namespace

Namespace provides a scope for Names.

apiVersion: v1

```
import "k8s.io/api/core/v1"
```

## Namespace

Namespace provides a scope for Names. Use of multiple namespaces is optional.

---

- **apiVersion:** v1
- **kind:** Namespace
- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([NamespaceSpec](#))

Spec defines the behavior of the Namespace. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([NamespaceStatus](#))

Status describes the current status of a Namespace. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## NamespaceSpec

NamespaceSpec describes the attributes on a Namespace.

---

- **finalizers** ([]string)

Finalizers is an opaque list of values that must be empty to permanently remove object from storage. More info: <https://kubernetes.io/docs/tasks/administer-cluster/namespaces/>

## NamespaceStatus

NamespaceStatus is information about the current status of a Namespace.

---

- **conditions** ([]NamespaceCondition)

*Patch strategy: merge on key type*

Represents the latest available observations of a namespace's current state.

*NamespaceCondition contains details about state of namespace.*

- **conditions.status** (string), required

Status of the condition, one of True, False, Unknown.

- **conditions.type** (string), required

Type of namespace controller condition.

- **conditions.lastTransitionTime** (Time)

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

- **conditions.reason** (string)

- **phase** (string)

Phase is the current lifecycle phase of the namespace. More info: <https://kubernetes.io/docs/tasks/administer-cluster/namespaces/>

## NamespaceList

NamespaceList is a list of Namespaces.

---

- **apiVersion:** v1
- **kind:** NamespaceList
- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]Namespace](#)), required

Items is the list of Namespace objects in the list. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/>

## Operations

---

## get read the specified Namespace

### HTTP Request

GET /api/v1/namespaces/{name}

### Parameters

- **name** (*in path*): string, required

name of the Namespace

- **pretty** (*in query*): string

[pretty](#)

### Response

200 ([Namespace](#)): OK

401: Unauthorized

## get read status of the specified Namespace

### HTTP Request

GET /api/v1/namespaces/{name}/status

### Parameters

- **name** (*in path*): string, required

name of the Namespace

- **pretty** (*in query*): string

[pretty](#)

### Response

200 ([Namespace](#)): OK

401: Unauthorized

## list list or watch objects of kind Namespace

### HTTP Request

GET /api/v1/namespaces

## Parameters

- **allowWatchBookmarks** (*in query*): boolean

[allowWatchBookmarks](#)

- **continue** (*in query*): string

[continue](#)

- **fieldSelector** (*in query*): string

[fieldSelector](#)

- **labelSelector** (*in query*): string

[labelSelector](#)

- **limit** (*in query*): integer

[limit](#)

- **pretty** (*in query*): string

[pretty](#)

- **resourceVersion** (*in query*): string

[resourceVersion](#)

- **resourceVersionMatch** (*in query*): string

[resourceVersionMatch](#)

- **sendInitialEvents** (*in query*): boolean

[sendInitialEvents](#)

- **timeoutSeconds** (*in query*): integer

[timeoutSeconds](#)

- **watch** (*in query*): boolean

[watch](#)

## Response

200 ([NamespaceList](#)): OK

401: Unauthorized

## create create a Namespace

### HTTP Request

POST /api/v1/namespaces

### Parameters

- **body**: [Namespace](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string

### Response

200 ([Namespace](#)): OK

201 ([Namespace](#)): Created

202 ([Namespace](#)): Accepted

401: Unauthorized

## update replace the specified Namespace

### HTTP Request

PUT /api/v1/namespaces/{name}

### Parameters

- **name** (*in path*): string, required  
name of the Namespace
- **body**: [Namespace](#), required
- **dryRun** (*in query*): string  
[dryRun](#)

- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([Namespace](#)): OK

201 ([Namespace](#)): Created

401: Unauthorized

## update replace finalize of the specified Namespace

### HTTP Request

PUT /api/v1/namespaces/{name}/finalize

### Parameters

- **name** (*in path*): string, required  
name of the Namespace
- **body**: [Namespace](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([Namespace](#)): OK

201 ([Namespace](#)): Created

401: Unauthorized

## update replace status of the specified Namespace

### HTTP Request

PUT /api/v1/namespaces/{name}/status

### Parameters

- **name** (*in path*): string, required  
name of the Namespace
- **body**: [Namespace](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)

# Event

Event is a report of an event somewhere in the cluster.

apiVersion: events.k8s.io/v1

import "k8s.io/api/events/v1"

## Event

Event is a report of an event somewhere in the cluster. It generally denotes some state change in the system. Events have a limited retention time and triggers and messages may evolve with time. Event consumers should not rely on the timing of an event with a given Reason reflecting a consistent underlying trigger, or the continued existence of events with that Reason. Events should be treated as informative, best-effort, supplemental data.

---

- **apiVersion:** events.k8s.io/v1

- **kind:** Event

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **eventTime** (MicroTime), required

eventTime is the time when this Event was first observed. It is required.

*MicroTime is version of Time with microsecond level precision.*

- **action** (string)

action is what action was taken/failed regarding to the regarding object. It is machine-readable. This field cannot be empty for new Events and it can have at most 128 characters.

- **deprecatedCount** (int32)

deprecatedCount is the deprecated field assuring backward compatibility with core.v1 Event type.

- **deprecatedFirstTimestamp** (Time)

deprecatedFirstTimestamp is the deprecated field assuring backward compatibility with core.v1 Event type.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **deprecatedLastTimestamp** (Time)

deprecatedLastTimestamp is the deprecated field assuring backward compatibility with core.v1 Event type.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **deprecatedSource** (EventSource)

deprecatedSource is the deprecated field assuring backward compatibility with core.v1 Event type.

*EventSource contains information for an event.*

- **deprecatedSource.component** (string)

Component from which the event is generated.

- **deprecatedSource.host** (string)

Node name on which the event is generated.

- **note** (string)

note is a human-readable description of the status of this operation. Maximal length of the note is 1kB, but libraries should be prepared to handle values up to 64kB.

- **reason** (string)

reason is why the action was taken. It is human-readable. This field cannot be empty for new Events and it can have at most 128 characters.

- **regarding** ([ObjectReference](#))

regarding contains the object this Event is about. In most cases it's an Object reporting controller implements, e.g. ReplicaSetController implements ReplicaSets and this event is emitted because it acts on some changes in a ReplicaSet object.

- **related** ([ObjectReference](#))

related is the optional secondary object for more complex actions. E.g. when regarding object triggers a creation or deletion of related object.

- **reportingController** (string)

reportingController is the name of the controller that emitted this Event, e.g. kubernetes.io/kubelet. This field cannot be empty for new Events.

- **reportingInstance** (string)

reportingInstance is the ID of the controller instance, e.g. kubelet-xyzf. This field cannot be empty for new Events and it can have at most 128 characters.

- **series** (EventSeries)

series is data about the Event series this event represents or nil if it's a singleton Event.

*EventSeries contain information on series of events, i.e. thing that was/is happening continuously for some time. How often to update the EventSeries is up to the event reporters. The default event reporter in "k8s.io/client-go/tools/events/event\_broadcaster.go" shows how this struct is updated on heartbeats and can guide customized reporter implementations.*

- **series.count** (int32), required

count is the number of occurrences in this series up to the last heartbeat time.

- **series.lastObservedTime** (MicroTime), required

lastObservedTime is the time when last Event from the series was seen before last heartbeat.

*MicroTime is version of Time with microsecond level precision.*

- **type** (string)

type is the type of this event (Normal, Warning), new types could be added in the future. It is machine-readable. This field cannot be empty for new Events.

## EventList

EventList is a list of Event objects.

---

- **apiVersion**: events.k8s.io/v1

- **kind**: EventList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]Event](#)), required

items is a list of schema objects.

## Operations

---

### get read the specified Event

#### HTTP Request

## update replace the specified Event

### HTTP Request

PUT /apis/events.k8s.io/v1/namespaces/{namespace}/events/{name}

### Parameters

- **name** (*in path*): string, required  
name of the Event
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [Event](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([Event](#)): OK

201 ([Event](#)): Created

401: Unauthorized

## patch partially update the specified Event

### HTTP Request

PATCH /apis/events.k8s.io/v1/namespaces/{namespace}/events/{name}

### Parameters

- **name** (*in path*): string, required  
name of the Event
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [Patch](#), required
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldManager** (*in query*): string  
[fieldManager](#)
- **fieldValidation** (*in query*): string  
[fieldValidation](#)
- **force** (*in query*): boolean  
[force](#)
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([Event](#)): OK

201 ([Event](#)): Created

401: Unauthorized

## delete delete an Event

### HTTP Request

DELETE /apis/events.k8s.io/v1/namespaces/{namespace}/events/{name}

### Parameters

- **name** (*in path*): string, required  
name of the Event
- **namespace** (*in path*): string, required  
[namespace](#)
- **body**: [DeleteOptions](#)
- **dryRun** (*in query*): string  
[dryRun](#)
- **gracePeriodSeconds** (*in query*): integer  
[gracePeriodSeconds](#)
- **pretty** (*in query*): string  
[pretty](#)
- **propagationPolicy** (*in query*): string  
[propagationPolicy](#)

### Response

200 ([Status](#)): OK

202 ([Status](#)): Accepted

401: Unauthorized

## deletecollection delete collection of Event

### HTTP Request

DELETE /apis/events.k8s.io/v1/namespaces/{namespace}/events

### Parameters

- **namespace** (*in path*): string, required  
[namespace](#)

- **body:** [DeleteOptions](#)
- **continue** (*in query*): string  
[continue](#)
- **dryRun** (*in query*): string  
[dryRun](#)
- **fieldSelector** (*in query*): string  
[fieldSelector](#)
- **gracePeriodSeconds** (*in query*): integer  
[gracePeriodSeconds](#)
- **labelSelector** (*in query*): string  
[labelSelector](#)
- **limit** (*in query*): integer  
[limit](#)
- **pretty** (*in query*): string  
[pretty](#)
- **propagationPolicy** (*in query*): string  
[propagationPolicy](#)
- **resourceVersion** (*in query*): string  
[resourceVersion](#)
- **resourceVersionMatch** (*in query*): string  
[resourceVersionMatch](#)
- **sendInitialEvents** (*in query*): boolean  
[sendInitialEvents](#)
- **timeoutSeconds** (*in query*): integer  
[timeoutSeconds](#)

## Response

200 ([Status](#)): OK

401: Unauthorized

# APIService

APIService represents a server for a particular GroupVersion.

apiVersion: apiregistration.k8s.io/v1

```
import "k8s.io/kube-aggregator/pkg/apis/apiregistration/v1"
```

## APIService

APIService represents a server for a particular GroupVersion. Name must be "version.group".

---

- **apiVersion:** apiregistration.k8s.io/v1

- **kind:** APIService

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([APIServiceSpec](#))

Spec contains information for locating and communicating with a server

- **status** ([APIServiceStatus](#))

Status contains derived information about an API server

## APIServiceSpec

APIServiceSpec contains information for locating and communicating with a server. Only https is supported, though you are able to disable certificate verification.

---

- **groupPriorityMinimum** (int32), required

GroupPriorityMinimum is the priority this group should have at least. Higher priority means that the group is preferred by clients over lower priority ones. Note that other versions of this group might specify even higher GroupPriorityMinimum values such that the whole group gets a higher priority. The primary sort is based on GroupPriorityMinimum, ordered highest number to lowest (20 before 10). The secondary sort is based on the alphabetical comparison of the name of the object. (v1.bar before v1.foo) We'd recommend something like: \*.k8s.io (except extensions) at 18000 and PaaSes (OpenShift, Deis) are recommended to be in the 2000s

- **versionPriority** (int32), required

VersionPriority controls the ordering of this API version inside of its group. Must be greater than zero. The primary sort is based on VersionPriority, ordered highest to lowest (20 before 10). Since it's inside of a group, the number can be small, probably in the 10s.

In case of equal version priorities, the version string will be used to compute the order inside a group. If the version string is "kube-like", it will sort above non "kube-like" version strings, which are ordered lexicographically. "Kube-like" versions start with a "v", then are followed by a number (the major version), then optionally the string "alpha" or "beta" and another number (the minor version). These are sorted first by GA > beta > alpha (where GA is a version with no suffix such as beta or alpha), and then by comparing major version, then minor version. An example sorted list of versions: v10, v2, v1, v11beta2, v10beta3, v3beta1, v12alpha1, v11alpha2, foo1, foo10.

- **caBundle** ([]byte)

*Atomic: will be replaced during a merge*

CABundle is a PEM encoded CA bundle which will be used to validate an API server's serving certificate. If unspecified, system trust roots on the apiserver are used.

- **group** (string)

Group is the API group name this server hosts

- **insecureSkipTLSVerify** (boolean)

InsecureSkipTLSVerify disables TLS certificate verification when communicating with this server. This is strongly discouraged. You should use the CABundle instead.

- **service** (ServiceReference)

Service is a reference to the service for this API server. It must communicate on port 443. If the Service is nil, that means the handling for the API groupversion is handled locally on this server. The call will simply delegate to the normal handler chain to be fulfilled.

*ServiceReference holds a reference to Service.legacy.k8s.io*

- **service.name** (string)

Name is the name of the service

- **service.namespace** (string)

Namespace is the namespace of the service

- **service.port** (int32)

If specified, the port on the service that hosting webhook. Default to 443 for backward compatibility. port should be a valid port number (1-65535, inclusive).

- **version** (string)

Version is the API version this server hosts. For example, "v1"

## APIServiceStatus

APIServiceStatus contains derived information about an API server

- 
- **conditions** ([]APIServiceCondition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

Current service state of apiService.

*APIServiceCondition describes the state of an APIService at a particular point*

- **conditions.status** (string), required

Status is the status of the condition. Can be True, False, Unknown.

- **conditions.type** (string), required

Type is the type of the condition.

- **conditions.lastTransitionTime** (Time)

Last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

Human-readable message indicating details about last transition.

- **conditions.reason** (string)

Unique, one-word, CamelCase reason for the condition's last transition.

## APIServiceList

APIServiceList is a list of APIService objects.

- 
- **apiVersion**: apiregistration.k8s.io/v1

- **kind**: APIServiceList

- **metadata** ([ListMeta](#))

Standard list metadata More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([][APIService](#)), required

Items is the list of APIService

# Operations

# Lease

Lease defines a lease concept.

apiVersion: coordination.k8s.io/v1

import "k8s.io/api/coordination/v1"

## Lease

Lease defines a lease concept.

- 
- **apiVersion**: coordination.k8s.io/v1
  - **kind**: Lease

- **metadata** ([ObjectMeta](#))

More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([LeaseSpec](#))

spec contains the specification of the Lease. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## LeaseSpec

LeaseSpec is a specification of a Lease.

---

- **acquireTime** (MicroTime)

acquireTime is a time when the current lease was acquired.

*MicroTime is version of Time with microsecond level precision.*

- **holderIdentity** (string)

holderIdentity contains the identity of the holder of a current lease.

- **leaseDurationSeconds** (int32)

leaseDurationSeconds is a duration that candidates for a lease need to wait to force acquire it. This is measure against time of last observed renewTime.

- **leaseTransitions** (int32)

leaseTransitions is the number of transitions of a lease between holders.

- **renewTime** (MicroTime)

renewTime is a time when the current holder of a lease has last updated the lease.

*MicroTime is version of Time with microsecond level precision.*

## LeaseList

LeaseList is a list of Lease objects.

---

- **apiVersion**: coordination.k8s.io/v1

- **kind**: LeaseList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([[Lease](#)]), required  
items is a list of schema objects.

## Operations

# RuntimeClass

RuntimeClass defines a class of container runtime supported in the cluster.

apiVersion: node.k8s.io/v1

import "k8s.io/api/node/v1"

## RuntimeClass

RuntimeClass defines a class of container runtime supported in the cluster. The RuntimeClass is used to determine which container runtime is used to run all containers in a pod.

RuntimeClasses are manually defined by a user or cluster provisioner, and referenced in the PodSpec. The Kubelet is responsible for resolving the RuntimeClassName reference before running the pod. For more details, see <https://kubernetes.io/docs/concepts/containers/runtime-class/>

- 
- **apiVersion**: node.k8s.io/v1
  - **kind**: RuntimeClass
  - **metadata** ([ObjectMeta](#))

More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **handler** (string), required

handler specifies the underlying runtime and configuration that the CRI implementation will use to handle pods of this class. The possible values are specific to the node & CRI configuration. It is assumed that all handlers are available on every node, and handlers of the same name are equivalent on every node. For example, a handler called "runc" might specify that the runc OCI runtime (using native Linux containers) will be used to run the containers in a pod. The Handler must be lowercase, conform to the DNS Label (RFC 1123) requirements, and is immutable.

- **overhead** (Overhead)

overhead represents the resource overhead associated with running a pod for a given RuntimeClass. For more details, see <https://kubernetes.io/docs/concepts/scheduling-eviction/pod-overhead/>

*Overhead structure represents the resource overhead associated with running a pod.*

- **overhead.podFixed** (map[string][Quantity](#))

podFixed represents the fixed resource overhead associated with running a pod.

- **scheduling** (Scheduling)

scheduling holds the scheduling constraints to ensure that pods running with this RuntimeClass are scheduled to nodes that support it. If scheduling is nil, this RuntimeClass is assumed to be supported by all nodes.

*Scheduling specifies the scheduling constraints for nodes supporting a RuntimeClass.*

- **scheduling.nodeSelector** (map[string]string)

nodeSelector lists labels that must be present on nodes that support this RuntimeClass. Pods using this RuntimeClass can only be scheduled to a node matched by this selector. The RuntimeClass nodeSelector is merged with a pod's existing nodeSelector. Any conflicts will cause the pod to be rejected in admission.

- **scheduling.tolerations** ([]Toleration)

*Atomic: will be replaced during a merge*

tolerations are appended (excluding duplicates) to pods running with this RuntimeClass during admission, effectively unioning the set of nodes tolerated by the pod and the RuntimeClass.

*The pod this Toleration is attached to tolerates any taint that matches the triple <key,value,effect> using the matching operator .*

- **scheduling.tolerations.key** (string)

Key is the taint key that the toleration applies to. Empty means match all taint keys. If the key is empty, operator must be Exists; this combination means to match all values and all keys.

- **scheduling.tolerations.operator** (string)

Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

- **scheduling.tolerations.value** (string)

Value is the taint value the toleration matches to. If the operator is Exists, the value should be empty, otherwise just a regular string.

- **scheduling.tolerations.effect** (string)

Effect indicates the taint effect to match. Empty means match all taint effects. When specified, allowed values are NoSchedule, PreferNoSchedule and NoExecute.

- **scheduling.tolerations.tolerationSeconds** (int64)

TolerationSeconds represents the period of time the toleration (which must be of effect NoExecute, otherwise this field is ignored) tolerates the taint. By default, it is not set, which means tolerate the taint forever (do not evict). Zero and negative values will be treated as 0 (evict immediately) by the system.

## RuntimeClassList

RuntimeClassList is a list of RuntimeClass objects.

---

- **apiVersion**: node.k8s.io/v1

- **kind**: RuntimeClassList

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]RuntimeClass](#)), required

items is a list of schema objects.

## Operations

---

### get read the specified RuntimeClass

# FlowSchema v1beta3

FlowSchema defines the schema of a group of flows.

apiVersion: flowcontrol.apiserver.k8s.io/v1beta3

import "k8s.io/api/flowcontrol/v1beta3"

## FlowSchema

FlowSchema defines the schema of a group of flows. Note that a flow is made up of a set of inbound API requests with similar attributes and is identified by a pair of strings: the name of the FlowSchema and a "flow distinguisher".

---

- **apiVersion:** flowcontrol.apiserver.k8s.io/v1beta3

- **kind:** FlowSchema

- **metadata** ([ObjectMeta](#))

metadata is the standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([FlowSchemaSpec](#))

spec is the specification of the desired behavior of a FlowSchema. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([FlowSchemaStatus](#))

status is the current status of a FlowSchema. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## FlowSchemaSpec

FlowSchemaSpec describes how the FlowSchema's specification looks like.

---

- **priorityLevelConfiguration** (PriorityLevelConfigurationReference), required

`priorityLevelConfiguration` should reference a `PriorityLevelConfiguration` in the cluster. If the reference cannot be resolved, the `FlowSchema` will be ignored and marked as invalid in its status. Required.

*`PriorityLevelConfigurationReference` contains information that points to the "request-priority" being used.*

- **`priorityLevelConfiguration.name`** (string), required

`name` is the name of the priority level configuration being referenced Required.

- **`distinguisherMethod`** (`FlowDistinguisherMethod`)

`distinguisherMethod` defines how to compute the flow distinguisher for requests that match this schema. `nil` specifies that the distinguisher is disabled and thus will always be the empty string.

*`FlowDistinguisherMethod` specifies the method of a flow distinguisher.*

- **`distinguisherMethod.type`** (string), required

`type` is the type of flow distinguisher method The supported types are "ByUser" and "ByNamespace". Required.

- **`matchingPrecedence`** (int32)

`matchingPrecedence` is used to choose among the `FlowSchemas` that match a given request. The chosen `FlowSchema` is among those with the numerically lowest (which we take to be logically highest) `MatchingPrecedence`. Each `MatchingPrecedence` value must be ranged in [1,10000]. Note that if the precedence is not specified, it will be set to 1000 as default.

- **`rules`** (`[]PolicyRulesWithSubjects`)

*Atomic: will be replaced during a merge*

`rules` describes which requests will match this flow schema. This `FlowSchema` matches a request if and only if at least one member of `rules` matches the request. if it is an empty slice, there will be no requests matching the `FlowSchema`.

*`PolicyRulesWithSubjects` prescribes a test that applies to a request to an apiserver. The test considers the subject making the request, the verb being requested, and the resource to be acted upon. This `PolicyRulesWithSubjects` matches a request if and only if both (a) at least one member of `subjects` matches the request and (b) at least one member of `resourceRules` or `nonResourceRules` matches the request.*

- **`rules.subjects`** (`[]Subject`), required

*Atomic: will be replaced during a merge*

`subjects` is the list of normal user, serviceaccount, or group that this rule cares about. There must be at least one member in this slice. A slice that includes both the `system:authenticated` and `system:unauthenticated` user groups matches every request. Required.

*Subject matches the originator of a request, as identified by the request authentication system. There are three ways of matching an originator; by user, group, or service account.*

- **rules.subjects.kind** (string), required

kind indicates which one of the other fields is non-empty. Required

- **rules.subjects.group** (GroupSubject)

group matches based on user group name.

*GroupSubject holds detailed information for group-kind subject.*

- **rules.subjects.group.name** (string), required

name is the user group that matches, or "\*" to match all user groups. See <https://github.com/kubernetes/apiserver/blob/master/pkg/authentication/user/user.go> for some well-known group names. Required.

- **rules.subjects.serviceAccount** (ServiceAccountSubject)

serviceAccount matches ServiceAccounts.

*ServiceAccountSubject holds detailed information for service-account-kind subject.*

- **rules.subjects.serviceAccount.name** (string), required

name is the name of matching ServiceAccount objects, or "\*" to match regardless of name. Required.

- **rules.subjects.serviceAccount.namespace** (string), required

namespace is the namespace of matching ServiceAccount objects. Required.

- **rules.subjects.user** (UserSubject)

user matches based on username.

*UserSubject holds detailed information for user-kind subject.*

- **rules.subjects.user.name** (string), required

name is the username that matches, or "\*" to match all usernames. Required.

- **rules.nonResourceRules** ([]NonResourcePolicyRule)

*Atomic: will be replaced during a merge*

nonResourceRules is a list of NonResourcePolicyRules that identify matching requests according to their verb and the target non-resource URL.

*NonResourcePolicyRule is a predicate that matches non-resource requests according to their verb and the target non-resource URL. A NonResourcePolicyRule matches a request if and only if both (a) at least one member of verbs matches the request and (b) at least one member of nonResourceURLs matches the request.*

- **rules.nonResourceRules.nonResourceURLs** ([]string), required

*Set: unique values will be kept during a merge*

nonResourceURLs is a set of url prefixes that a user should have access to and may not be empty. For example:

- `"/healthz"` is legal
- `"/hea*"` is illegal
- `"/hea"` is legal but matches nothing
- `"/hea/*"` also matches nothing
- `"/healthz/"` matches all per-component health checks. `""` matches all non-resource urls. if it is present, it must be the only entry. Required.

- **rules.nonResourceRules.verbs** ([]string), required

*Set: unique values will be kept during a merge*

verbs is a list of matching verbs and may not be empty. `""` matches all verbs. If it is present, it must be the only entry. Required.

- **rules.resourceRules** ([]ResourcePolicyRule)

*Atomic: will be replaced during a merge*

resourceRules is a slice of ResourcePolicyRules that identify matching requests according to their verb and the target resource. At least one of resourceRules and nonResourceRules has to be non-empty.

*ResourcePolicyRule is a predicate that matches some resource requests, testing the request's verb and the target resource. A ResourcePolicyRule matches a resource request if and only if: (a) at least one member of verbs matches the request, (b) at least one member of apiGroups matches the request, (c) at least one member of resources matches the request, and (d) either (d1) the request does not specify a namespace (i.e., Namespace=="") and clusterScope is true or (d2) the request specifies a namespace and least one member of namespaces matches the request's namespace.*

- **rules.resourceRules.apiGroups** ([]string), required

*Set: unique values will be kept during a merge*

apiGroups is a list of matching API groups and may not be empty. `""` matches all API groups and, if present, must be the only entry. Required.

- **rules.resourceRules.resources** ([]string), required

*Set: unique values will be kept during a merge*

resources is a list of matching resources (i.e., lowercase and plural) with, if desired, subresource. For example, [ `"services"`, `"nodes/status"` ]. This list may

not be empty. "\*" matches all resources and, if present, must be the only entry. Required.

- **rules.resourceRules.verbs** ([]string), required

*Set: unique values will be kept during a merge*

verbs is a list of matching verbs and may not be empty. "\*" matches all verbs and, if present, must be the only entry. Required.

- **rules.resourceRules.clusterScope** (boolean)

clusterScope indicates whether to match requests that do not specify a namespace (which happens either because the resource is not namespaced or the request targets all namespaces). If this field is omitted or false then the namespaces field must contain a non-empty list.

- **rules.resourceRules.namespaces** ([]string)

*Set: unique values will be kept during a merge*

namespaces is a list of target namespaces that restricts matches. A request that specifies a target namespace matches only if either (a) this list contains that target namespace or (b) this list contains "". *Note that "" matches any specified namespace but does not match a request that does not specify a namespace (see the clusterScope field for that).* This list may be empty, but only if clusterScope is true.

## FlowSchemaStatus

FlowSchemaStatus represents the current state of a FlowSchema.

---

- **conditions** ([]FlowSchemaCondition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

conditions is a list of the current states of FlowSchema.

*FlowSchemaCondition describes conditions for a FlowSchema.*

- **conditions.lastTransitionTime** (Time)

lastTransitionTime is the last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)

`message` is a human-readable message indicating details about last transition.

- **conditions.reason** (string)

`reason` is a unique, one-word, CamelCase reason for the condition's last transition.

- **conditions.status** (string)

`status` is the status of the condition. Can be True, False, Unknown. Required.

- **conditions.type** (string)

`type` is the type of the condition. Required.

## FlowSchemaList

FlowSchemaList is a list of FlowSchema objects.

- 
- **apiVersion:** flowcontrol.apiserver.k8s.io/v1beta3
  - **kind:** FlowSchemaList
  - **metadata** ([ListMeta](#))

`metadata` is the standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([\[\]FlowSchema](#)), required

`items` is a list of FlowSchemas.

## Operations

# PriorityLevelConfiguration v1beta3

PriorityLevelConfiguration represents the configuration of a priority level.

apiVersion: flowcontrol.apiserver.k8s.io/v1beta3

import "k8s.io/api/flowcontrol/v1beta3"

## PriorityLevelConfiguration

PriorityLevelConfiguration represents the configuration of a priority level.

- 
- **apiVersion:** flowcontrol.apiserver.k8s.io/v1beta3
  - **kind:** PriorityLevelConfiguration
  - **metadata** ([ObjectMeta](#))

metadata is the standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([PriorityLevelConfigurationSpec](#))

spec is the specification of the desired behavior of a "request-priority". More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

- **status** ([PriorityLevelConfigurationStatus](#))

status is the current status of a "request-priority". More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## PriorityLevelConfigurationSpec

PriorityLevelConfigurationSpec specifies the configuration of a priority level.

- 
- **type** (string), required

type indicates whether this priority level is subject to limitation on request execution. A value of "Exempt" means that requests of this priority level are not subject to a limit (and thus are never queued) and do not detract from the capacity made available to other

priority levels. A value of "Limited" means that (a) requests of this priority level *are* subject to limits and (b) some of the server's limited capacity is made available exclusively to this priority level. Required.

- **exempt** (ExemptPriorityLevelConfiguration)

`exempt` specifies how requests are handled for an exempt priority level. This field **MUST** be empty if type is "Limited". This field **MAY** be non-empty if type is "Exempt". If empty and type is "Exempt" then the default values for ExemptPriorityLevelConfiguration apply.

*ExemptPriorityLevelConfiguration describes the configurable aspects of the handling of exempt requests. In the mandatory exempt configuration object the values in the fields here can be modified by authorized users, unlike the rest of the spec.*

- **exempt.lendablePercent** (int32)

`lendablePercent` prescribes the fraction of the level's NominalCL that can be borrowed by other priority levels. This value of this field must be between 0 and 100, inclusive, and it defaults to 0. The number of seats that other levels can borrow from this level, known as this level's LendableConcurrencyLimit (LendableCL), is defined as follows.

$$\text{LendableCL}(i) = \text{round}(\text{NominalCL}(i) * \text{lendablePercent}(i)/100.0)$$

- **exempt.nominalConcurrencyShares** (int32)

`nominalConcurrencyShares` (NCS) contributes to the computation of the NominalConcurrencyLimit (NominalCL) of this level. This is the number of execution seats nominally reserved for this priority level. This **DOES NOT** limit the dispatching from this priority level but affects the other priority levels through the borrowing mechanism. The server's concurrency limit (ServerCL) is divided among all the priority levels in proportion to their NCS values:

$$\text{NominalCL}(i) = \text{ceil}(\text{ServerCL} * \text{NCS}(i) / \text{sum\_ncs}) \quad \text{sum\_ncs} = \text{sum}[\text{priority level } k] \text{NCS}(k)$$

Bigger numbers mean a larger nominal concurrency limit, at the expense of every other priority level. This field has a default value of zero.

- **limited** (LimitedPriorityLevelConfiguration)

`limited` specifies how requests are handled for a Limited priority level. This field must be non-empty if and only if type is "Limited".

\*LimitedPriorityLevelConfiguration specifies how to handle requests that are subject to limits. It addresses two issues:

- How are requests for this priority level limited?
  - What should be done with requests that exceed the limit?\*
  - **limited.borrowingLimitPercent** (int32)

`borrowingLimitPercent`, if present, configures a limit on how many seats this priority level can borrow from other priority levels. The limit is known as this

level's `BorrowingConcurrencyLimit` (`BorrowingCL`) and is a limit on the total number of seats that this level may borrow at any one time. This field holds the ratio of that limit to the level's nominal concurrency limit. When this field is non-nil, it must hold a non-negative integer and the limit is calculated as follows.

$$\text{BorrowingCL}(i) = \text{round}(\text{NominalCL}(i) * \text{borrowingLimitPercent}(i)/100.0)$$

The value of this field can be more than 100, implying that this priority level can borrow a number of seats that is greater than its own nominal concurrency limit (`NominalCL`). When this field is left nil, the limit is effectively infinite.

- **limited.lendablePercent** (int32)

`lendablePercent` prescribes the fraction of the level's `NominalCL` that can be borrowed by other priority levels. The value of this field must be between 0 and 100, inclusive, and it defaults to 0. The number of seats that other levels can borrow from this level, known as this level's `LendableConcurrencyLimit` (`LendableCL`), is defined as follows.

$$\text{LendableCL}(i) = \text{round}(\text{NominalCL}(i) * \text{lendablePercent}(i)/100.0)$$

- **limited.limitResponse** (`LimitResponse`)

`limitResponse` indicates what to do with requests that can not be executed right now

*LimitResponse defines how to handle requests that can not be executed right now.*

- **limited.limitResponse.type** (string), required

`type` is "Queue" or "Reject". "Queue" means that requests that can not be executed upon arrival are held in a queue until they can be executed or a queuing limit is reached. "Reject" means that requests that can not be executed upon arrival are rejected. Required.

- **limited.limitResponse.queuing** (`QueuingConfiguration`)

`queuing` holds the configuration parameters for queuing. This field may be non-empty only if `type` is "Queue".

*QueuingConfiguration holds the configuration parameters for queuing*

- **limited.limitResponse.queuing.handSize** (int32)

`handSize` is a small positive number that configures the shuffle sharding of requests into queues. When enqueueing a request at this priority level the request's flow identifier (a string pair) is hashed and the hash value is used to shuffle the list of queues and deal a hand of the size specified here. The request is put into one of the shortest queues in that hand. `handSize` must be no larger than queues, and should be significantly smaller (so that a few heavy flows do not saturate most of the queues). See the user-facing documentation for more extensive guidance on setting this field. This field has a default value of 8.

- **limited.limitResponse.queueing.queueLengthLimit** (int32)

queueLengthLimit is the maximum number of requests allowed to be waiting in a given queue of this priority level at a time; excess requests are rejected. This value must be positive. If not specified, it will be defaulted to 50.

- **limited.limitResponse.queueing.queues** (int32)

queues is the number of queues for this priority level. The queues exist independently at each apiserver. The value must be positive. Setting it to 1 effectively precludes shufflesharding and thus makes the distinguisher method of associated flow schemas irrelevant. This field has a default value of 64.

- **limited.nominalConcurrencyShares** (int32)

nominalConcurrencyShares (NCS) contributes to the computation of the NominalConcurrencyLimit (NominalCL) of this level. This is the number of execution seats available at this priority level. This is used both for requests dispatched from this priority level as well as requests dispatched from other priority levels borrowing seats from this level. The server's concurrency limit (ServerCL) is divided among the Limited priority levels in proportion to their NCS values:

$$\text{NominalCL}(i) = \text{ceil}(\text{ServerCL} * \text{NCS}(i) / \text{sum\_ncs}) \quad \text{sum\_ncs} = \sum[\text{priority level } k] \text{NCS}(k)$$

Bigger numbers mean a larger nominal concurrency limit, at the expense of every other priority level. This field has a default value of 30.

## PriorityLevelConfigurationStatus

PriorityLevelConfigurationStatus represents the current state of a "request-priority".

---

- **conditions** ([]PriorityLevelConfigurationCondition)

*Patch strategy: merge on key type*

*Map: unique values on key type will be kept during a merge*

conditions is the current state of "request-priority".

*PriorityLevelConfigurationCondition defines the condition of priority level.*

- **conditions.lastTransitionTime** (Time)

lastTransitionTime is the last time the condition transitioned from one status to another.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **conditions.message** (string)  
message is a human-readable message indicating details about last transition.
- **conditions.reason** (string)  
reason is a unique, one-word, CamelCase reason for the condition's last transition.
- **conditions.status** (string)  
status is the status of the condition. Can be True, False, Unknown. Required.
- **conditions.type** (string)  
type is the type of the condition. Required.

## PriorityLevelConfigurationList

PriorityLevelConfigurationList is a list of PriorityLevelConfiguration objects.

---

- **apiVersion**: flowcontrol.apiserver.k8s.io/v1beta3
- **kind**: PriorityLevelConfigurationList
- **metadata** ([ListMeta](#))  
metadata is the standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>
- **items** ([\[\]PriorityLevelConfiguration](#)), required  
items is a list of request-priorities.

## Operations

---

### get read the specified PriorityLevelConfiguration

#### HTTP Request

GET /apis/flowcontrol.apiserver.k8s.io/v1beta3/prioritylevelconfigurations/{name}

#### Parameters

- **name** (*in path*): string, required  
name of the PriorityLevelConfiguration
- **pretty** (*in query*): string  
[pretty](#)

## Response

200 ([PriorityLevelConfiguration](#)): OK

401: Unauthorized

## get read status of the specified PriorityLevelConfiguration

### HTTP Request

GET /apis/flowcontrol.apiserver.k8s.io/v1beta3/prioritylevelconfigurations/{name}/status

### Parameters

202 ([Binding](#)): Accepted

401: Unauthorized

# ComponentStatus

ComponentStatus (and ComponentStatusList) holds the cluster validation info.

apiVersion: v1

import "k8s.io/api/core/v1"

## ComponentStatus

ComponentStatus (and ComponentStatusList) holds the cluster validation info. Deprecated: This API is deprecated in v1.19+

- 
- **apiVersion:** v1
  - **kind:** ComponentStatus
  - **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **conditions** ([]ComponentCondition)

*Patch strategy: merge on key type*

List of component conditions observed

*Information about the condition of a component.*

- **conditions.status** (string), required

Status of the condition for a component. Valid values for "Healthy": "True", "False", or "Unknown".

- **conditions.type** (string), required  
Type of condition for a component. Valid value: "Healthy"
- **conditions.error** (string)  
Condition error code for a component. For example, a health check error code.
- **conditions.message** (string)  
Message about the condition for a component. For example, information about a health check.

## ComponentStatusList

Status of all the conditions for the component as a list of ComponentStatus objects. Deprecated: This API is deprecated in v1.19+

- 
- **apiVersion:** v1
  - **kind:** ComponentStatusList
  - **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **items** ([\[\]ComponentStatus](#)), required  
List of ComponentStatus objects.

## Operations

---

# ClusterCIDR v1alpha1

ClusterCIDR represents a single configuration for per-Node Pod CIDR allocations when the MultiCIDRRangeAllocator is enabled (see the config for kube-controller-manager).

apiVersion: networking.k8s.io/v1alpha1

```
import "k8s.io/api/networking/v1alpha1"
```

## ClusterCIDR

ClusterCIDR represents a single configuration for per-Node Pod CIDR allocations when the MultiCIDRRangeAllocator is enabled (see the config for kube-controller-manager). A cluster may have any number of ClusterCIDR resources, all of which will be considered when allocating a CIDR for a Node. A ClusterCIDR is eligible to be used for a given Node when the node selector matches the node in question and has free CIDRs to allocate. In case of multiple matching ClusterCIDR resources, the allocator will attempt to break ties using internal heuristics, but any ClusterCIDR whose node selector matches the Node may be used.

---

- **apiVersion:** networking.k8s.io/v1alpha1

- **kind:** ClusterCIDR

- **metadata** ([ObjectMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **spec** ([ClusterCIDRSpec](#))

spec is the desired state of the ClusterCIDR. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## ClusterCIDRSpec

ClusterCIDRSpec defines the desired state of ClusterCIDR.

---

- **perNodeHostBits** (int32), required

perNodeHostBits defines the number of host bits to be configured per node. A subnet mask determines how much of the address is used for network bits and host bits. For example an IPv4 address of 192.168.0.0/24, splits the address into 24 bits for the network portion and 8 bits for the host portion. To allocate 256 IPs, set this field to 8 (a /24 mask for IPv4 or a /120 for IPv6). Minimum value is 4 (16 IPs). This field is immutable.

- **ipv4** (string)

ipv4 defines an IPv4 IP block in CIDR notation(e.g. "10.0.0.0/8"). At least one of ipv4 and ipv6 must be specified. This field is immutable.

- **ipv6** (string)

ipv6 defines an IPv6 IP block in CIDR notation(e.g. "2001:db8::/64"). At least one of ipv4 and ipv6 must be specified. This field is immutable.

- **nodeSelector** (NodeSelector)

nodeSelector defines which nodes the config is applicable to. An empty or nil nodeSelector selects all nodes. This field is immutable.

*A node selector represents the union of the results of one or more label queries over a set of nodes; that is, it represents the OR of the selectors represented by the node selector terms.*

- **nodeSelector.nodeSelectorTerms** ([]NodeSelectorTerm), required

Required. A list of node selector terms. The terms are ORed.

*A null or empty node selector term matches no objects. The requirements of them are ANDed. The TopologySelectorTerm type implements a subset of the NodeSelectorTerm.*

- **nodeSelector.nodeSelectorTerms.matchExpressions**  
([][NodeSelectorRequirement](#))

A list of node selector requirements by node's labels.

- **nodeSelector.nodeSelectorTerms.matchFields**  
([][NodeSelectorRequirement](#))

A list of node selector requirements by node's fields.

## ClusterCIDRList

ClusterCIDRList contains a list of ClusterCIDR.

- 
- **apiVersion**: networking.k8s.io/v1alpha1
  - **kind**: ClusterCIDRList
  - **metadata** ([ListMeta](#))

Standard object's metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

- **items** ([][ClusterCIDR](#)), required  
items is the list of ClusterCIDRs.

## Operations

# Common Definitions

---

## [DeleteOptions](#)

DeleteOptions may be provided when deleting an API object.

## [LabelSelector](#)

A label selector is a label query over a set of resources.

### [ListMeta](#)

ListMeta describes metadata that synthetic resources must have, including lists and various status objects.

### [LocalObjectReference](#)

LocalObjectReference contains enough information to let you locate the referenced object inside the same namespace.

### [NodeSelectorRequirement](#)

A node selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

### [ObjectFieldSelector](#)

ObjectFieldSelector selects an APIVersioned field of an object.

### [ObjectMeta](#)

ObjectMeta is metadata that all persisted resources must have, which includes all objects users must create.

### [ObjectReference](#)

ObjectReference contains enough information to let you inspect or modify the referred object.

### [Patch](#)

Patch is provided to give a concrete name and type to the Kubernetes PATCH request body.

### [Quantity](#)

Quantity is a fixed-point representation of a number.

### [ResourceFieldSelector](#)

ResourceFieldSelector represents container resources (cpu, memory) and their output format.

### [Status](#)

Status is a return value for calls that don't return other objects.

### [TypedLocalObjectReference](#)

TypedLocalObjectReference contains enough information to let you locate the typed referenced object inside the same namespace.

# DeleteOptions

DeleteOptions may be provided when deleting an API object.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

DeleteOptions may be provided when deleting an API object.

---

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **dryRun** ([]string)

When present, indicates that modifications should not be persisted. An invalid or unrecognized dryRun directive will result in an error response and no further processing of the request. Valid values are: - All: all dry run stages will be processed

- **gracePeriodSeconds** (int64)

The duration in seconds before the object should be deleted. Value must be non-negative integer. The value zero indicates delete immediately. If this value is nil, the default grace period for the specified type will be used. Defaults to a per object value if not specified. zero means delete immediately.

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **orphanDependents** (boolean)

Deprecated: please use the PropagationPolicy, this field will be deprecated in 1.7. Should the dependent objects be orphaned. If true/false, the "orphan" finalizer will be added to/ removed from the object's finalizers list. Either this field or PropagationPolicy may be set, but not both.

- **preconditions** (Preconditions)

Must be fulfilled before a deletion is carried out. If not possible, a 409 Conflict status will be returned.

*Preconditions must be fulfilled before an operation (update, delete, etc.) is carried out.*

- **preconditions.resourceVersion** (string)

Specifies the target ResourceVersion

**preconditions.uid** (string)

- Specifies the target UID.

- **propagationPolicy** (string)

Whether and how garbage collection will be performed. Either this field or OrphanDependents may be set, but not both. The default policy is decided by the existing finalizer set in the metadata.finalizers and the resource-specific default policy. Acceptable values are: 'Orphan' - orphan the dependents; 'Background' - allow the garbage collector to delete the dependents in the background; 'Foreground' - a cascading policy that deletes all dependents in the foreground.

## LabelSelector

A label selector is a label query over a set of resources.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

A label selector is a label query over a set of resources. The result of matchLabels and matchExpressions are ANDed. An empty label selector matches all objects. A null label selector matches no objects.

---

- **matchExpressions** ([]LabelSelectorRequirement)

matchExpressions is a list of label selector requirements. The requirements are ANDed.

*A label selector requirement is a selector that contains values, a key, and an operator that relates the key and values.*

- **matchExpressions.key** (string), required

key is the label key that the selector applies to.

- **matchExpressions.operator** (string), required

operator represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists and DoesNotExist.

- **matchExpressions.values** ([]string)

values is an array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. This array is replaced during a strategic merge patch.

- **matchLabels** (map[string]string)

matchLabels is a map of {key,value} pairs. A single {key,value} in the matchLabels map is equivalent to an element of matchExpressions, whose key field is "key", the operator is "In", and the values array contains only "value". The requirements are ANDed.

# ListMeta

ListMeta describes metadata that synthetic resources must have, including lists and various status objects.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

ListMeta describes metadata that synthetic resources must have, including lists and various status objects. A resource may have only one of {ObjectMeta, ListMeta}.

---

- **continue** (string)

continue may be set if the user set a limit on the number of items returned, and indicates that the server has more data available. The value is opaque and may be used to issue another request to the endpoint that served this list to retrieve the next set of available objects. Continuing a consistent list may not be possible if the server configuration has changed or more than a few minutes have passed. The resourceVersion field returned when using this continue value will be identical to the value in the first response, unless you have received this token from an error message.

- **remainingItemCount** (int64)

remainingItemCount is the number of subsequent items in the list which are not included in this list response. If the list request contained label or field selectors, then the number of remaining items is unknown and the field will be left unset and omitted during serialization. If the list is complete (either because it is not chunking or because this is the last chunk), then there are no more remaining items and this field will be left unset and omitted during serialization. Servers older than v1.15 do not set this field. The intended use of the remainingItemCount is *estimating* the size of a collection. Clients should not rely on the remainingItemCount to be set or to be exact.

- **resourceVersion** (string)

String that identifies the server's internal version of this object that can be used by clients to determine when objects have changed. Value must be treated as opaque by clients and passed unmodified back to the server. Populated by the system. Read-only. More info:

<https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency>

- **selfLink** (string)

Deprecated: selfLink is a legacy read-only field that is no longer populated by the system.

## LocalObjectReference

LocalObjectReference contains enough information to let you locate the referenced object inside the same namespace.

```
import "k8s.io/api/core/v1"
```

LocalObjectReference contains enough information to let you locate the referenced object inside the same namespace.

---

- **name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

## NodeSelectorRequirement

A node selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

```
import "k8s.io/api/core/v1"
```

A node selector requirement is a selector that contains values, a key, and an operator that relates the key and values.

---

- **key** (string), required

The label key that the selector applies to.

- **operator** (string), required

Represents a key's relationship to a set of values. Valid operators are In, NotIn, Exists, DoesNotExist. Gt, and Lt.

- **values** ([]string)

An array of string values. If the operator is In or NotIn, the values array must be non-empty. If the operator is Exists or DoesNotExist, the values array must be empty. If the operator is Gt or Lt, the values array must have a single element, which will be interpreted as an integer. This array is replaced during a strategic merge patch.

## ObjectFieldSelector

ObjectFieldSelector selects an APIVersioned field of an object.

```
import "k8s.io/api/core/v1"
```

ObjectFieldSelector selects an APIVersioned field of an object.

---

- **fieldPath** (string), required

Path of the field to select in the specified API version.

- **apiVersion** (string)

Version of the schema the FieldPath is written in terms of, defaults to "v1".

# ObjectMeta

ObjectMeta is metadata that all persisted resources must have, which includes all objects users must create.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

ObjectMeta is metadata that all persisted resources must have, which includes all objects users must create.

---

- **name** (string)

Name must be unique within a namespace. Is required when creating resources, although some resources may allow a client to request the generation of an appropriate name automatically. Name is primarily intended for creation idempotence and configuration definition. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names#names>

- **generateName** (string)

GenerateName is an optional prefix, used by the server, to generate a unique name ONLY IF the Name field has not been provided. If this field is used, the name returned to the client will be different than the name passed. This value will also be combined with a unique suffix. The provided value has the same validation rules as the Name field, and may be truncated by the length of the suffix required to make the value unique on the server.

If this field is specified and the generated name exists, the server will return a 409.

Applied only if Name is not specified. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#idempotency>

- **namespace** (string)

Namespace defines the space within which each name must be unique. An empty namespace is equivalent to the "default" namespace, but "default" is the canonical representation. Not all objects are required to be scoped to a namespace - the value of this field for those objects will be empty.

Must be a DNS\_LABEL. Cannot be updated. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces>

- **labels** (map[string]string)

Map of string keys and values that can be used to organize and categorize (scope and select) objects. May match selectors of replication controllers and services. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/labels>

- **annotations** (map[string]string)

Annotations is an unstructured key value map stored with a resource that may be set by external tools to store and retrieve arbitrary metadata. They are not queryable and should

be preserved when modifying objects. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/annotations>

## System

- **finalizers** ([]string)

Must be empty before the object is deleted from the registry. Each entry is an identifier for the responsible component that will remove the entry from the list. If the `deletionTimestamp` of the object is non-nil, entries in this list can only be removed. Finalizers may be processed and removed in any order. Order is NOT enforced because it introduces significant risk of stuck finalizers. `finalizers` is a shared field, any actor with permission can reorder it. If the finalizer list is processed in order, then this can lead to a situation in which the component responsible for the first finalizer in the list is waiting for a signal (field value, external system, or other) produced by a component responsible for a finalizer later in the list, resulting in a deadlock. Without enforced ordering finalizers are free to order amongst themselves and are not vulnerable to ordering changes in the list.

- **managedFields** ([]ManagedFieldsEntry)

`ManagedFields` maps workflow-id and version to the set of fields that are managed by that workflow. This is mostly for internal housekeeping, and users typically shouldn't need to set or understand this field. A workflow can be the user's name, a controller's name, or the name of a specific apply path like "ci-cd". The set of fields is always in the version that the workflow used when modifying the object.

*ManagedFieldsEntry is a workflow-id, a FieldSet and the group version of the resource that the fieldset applies to.*

- **managedFields.apiVersion** (string)

`APIVersion` defines the version of this resource that this field set applies to. The format is "group/version" just like the top-level `APIVersion` field. It is necessary to track the version of a field set because it cannot be automatically converted.

- **managedFields.fieldsType** (string)

`FieldsType` is the discriminator for the different fields format and version. There is currently only one possible value: "FieldsV1"

- **managedFields.fieldsV1** (FieldsV1)

`FieldsV1` holds the first JSON version format as described in the "FieldsV1" type.

\*`FieldsV1` stores a set of fields in a data structure like a Trie, in JSON format.

Each key is either a '.' representing the field itself, and will always map to an empty set, or a string representing a sub-field or item. The string will follow one of these four formats: 'f:', where is the name of a field in a struct, or key in a map 'v:', where is the exact json formatted value of a list item 'i:', where is position of a item in a list 'k:', where is a map of a list item's key fields to their unique values If a key maps to an empty Fields value, the field that key represents is part of the set.

The exact format is defined in [sigs.k8s.io/structured-merge-diff](https://sigs.k8s.io/structured-merge-diff)\*

- **managedFields.manager** (string)

Manager is an identifier of the workflow managing these fields.

- **managedFields.operation** (string)

Operation is the type of operation which lead to this ManagedFieldsEntry being created. The only valid values for this field are 'Apply' and 'Update'.

- **managedFields.subresource** (string)

Subresource is the name of the subresource used to update that object, or empty string if the object was updated through the main resource. The value of this field is used to distinguish between managers, even if they share the same name. For example, a status update will be distinct from a regular update using the same manager name. Note that the APIVersion field is not related to the Subresource field and it always corresponds to the version of the main resource.

- **managedFields.time** (Time)

Time is the timestamp of when the ManagedFields entry was added. The timestamp will also be updated if a field is added, the manager changes any of the owned fields value or removes a field. The timestamp does not update when a field is removed from the entry because another manager took it over.

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **ownerReferences** ([]OwnerReference)

*Patch strategy: merge on key uid*

List of objects depended by this object. If ALL objects in the list have been deleted, this object will be garbage collected. If this object is managed by a controller, then an entry in this list will point to this controller, with the controller field set to true. There cannot be more than one managing controller.

*OwnerReference contains enough information to let you identify an owning object. An owning object must be in the same namespace as the dependent, or be cluster-scoped, so there is no namespace field.*

- **ownerReferences.apiVersion** (string), required

API version of the referent.

- **ownerReferences.kind** (string), required

Kind of the referent. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **ownerReferences.name** (string), required

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names#names>

- **ownerReferences.uid** (string), required

UID of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names#uids>

- **ownerReferences.blockOwnerDeletion** (boolean)

If true, AND if the owner has the "foregroundDeletion" finalizer, then the owner cannot be deleted from the key-value store until this reference is removed. See <https://kubernetes.io/docs/concepts/architecture/garbage-collection/#foreground-deletion> for how the garbage collector interacts with this field and enforces the foreground deletion. Defaults to false. To set this field, a user needs "delete" permission of the owner, otherwise 422 (Unprocessable Entity) will be returned.

- **ownerReferences.controller** (boolean)

If true, this reference points to the managing controller.

## Read-only

- **creationTimestamp** (Time)

CreationTimestamp is a timestamp representing the server time when this object was created. It is not guaranteed to be set in happens-before order across separate operations. Clients may not set this value. It is represented in RFC3339 form and is in UTC.

Populated by the system. Read-only. Null for lists. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

*Time is a wrapper around time.Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **deletionGracePeriodSeconds** (int64)

Number of seconds allowed for this object to gracefully terminate before it will be removed from the system. Only set when deletionTimestamp is also set. May only be shortened. Read-only.

- **deletionTimestamp** (Time)

DeletionTimestamp is RFC 3339 date and time at which this resource will be deleted. This field is set by the server when a graceful deletion is requested by the user, and is not directly settable by a client. The resource is expected to be deleted (no longer visible from resource lists, and not reachable by name) after the time in this field, once the finalizers list is empty. As long as the finalizers list contains items, deletion is blocked. Once the deletionTimestamp is set, this value may not be unset or be set further into the future, although it may be shortened or the resource may be deleted prior to this time. For example, a user may request that a pod is deleted in 30 seconds. The Kubelet will react by sending a graceful termination signal to the containers in the pod. After that 30 seconds, the Kubelet will send a hard termination signal (SIGKILL) to the container and after cleanup, remove the pod from the API. In the presence of network partitions, this object

may still exist after this timestamp, until an administrator or automated process can determine the resource is fully terminated. If not set, graceful deletion of the object has not been requested.

Populated by the system when a graceful deletion is requested. Read-only. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#metadata>

*Time is a wrapper around time. Time which supports correct marshaling to YAML and JSON. Wrappers are provided for many of the factory methods that the time package offers.*

- **generation** (int64)

A sequence number representing a specific generation of the desired state. Populated by the system. Read-only.

- **resourceVersion** (string)

An opaque value that represents the internal version of this object that can be used by clients to determine when objects have changed. May be used for optimistic concurrency, change detection, and the watch operation on a resource or set of resources. Clients must treat these values as opaque and passed unmodified back to the server. They may only be valid for a particular resource or set of resources.

Populated by the system. Read-only. Value must be treated as opaque by clients and . More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency>

- **selfLink** (string)

Deprecated: selfLink is a legacy read-only field that is no longer populated by the system.

- **uid** (string)

UID is the unique in time and space value for this object. It is typically generated by the server on successful creation of a resource and is not allowed to change on PUT operations.

Populated by the system. Read-only. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names#uids>

## ObjectReference

ObjectReference contains enough information to let you inspect or modify the referred object.

```
import "k8s.io/api/core/v1"
```

ObjectReference contains enough information to let you inspect or modify the referred object.

---

- **apiVersion** (string)

API version of the referent.

**fieldPath** (string)

- 

If referring to a piece of an object instead of an entire object, this string should contain a valid JSON/Go field access statement, such as `desiredState.manifest.containers[2]`. For example, if the object reference is to a container within a pod, this would take on a value like: `"spec.containers{name}"` (where "name" refers to the name of the container that triggered the event) or if no container name is specified `"spec.containers[2]"` (container with index 2 in this pod). This syntax is chosen only to have some well-defined way of referencing a part of an object.

- **kind** (string)

Kind of the referent. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **name** (string)

Name of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names>

- **namespace** (string)

Namespace of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/namespaces/>

- **resourceVersion** (string)

Specific resourceVersion to which this reference is made, if any. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#concurrency-control-and-consistency>

- **uid** (string)

UID of the referent. More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#uids>

## Patch

Patch is provided to give a concrete name and type to the Kubernetes PATCH request body.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

Patch is provided to give a concrete name and type to the Kubernetes PATCH request body.

---

## Quantity

Quantity is a fixed-point representation of a number.

```
import "k8s.io/apimachinery/pkg/api/resource"
```

Quantity is a fixed-point representation of a number. It provides convenient marshaling/unmarshaling in JSON and YAML, in addition to String() and AsInt64() accessors.

The serialization format is:

(Note that \<suffix> may be empty, from the "" case in \<decimalSI>.)

```
\<digit> ::= 0 | 1 | ... | 9 \<digits> ::= \<digit> | \<digit>\<digits> \<number> ::=
\<digits> | \<digits>.\<digits> | \<digits>. | \<digits> \<sign> ::= "+" | "-"
\<signedNumber> ::= \<number> | \<sign>\<number> \<suffix> ::= \<binarySI> |
\<decimalExponent> | \<decimalSI> \<binarySI> ::= Ki | Mi | Gi | Ti | Pi | Ei
```

(International System of units; See: <http://physics.nist.gov/cuu/Units/binary.html>)

```
\<decimalSI> ::= m | "" | k | M | G | T | P | E
```

(Note that 1024 = 1Ki but 1000 = 1k; I didn't choose the capitalization.)

```
\<decimalExponent> ::= "e" \<signedNumber> | "E" \<signedNumber> ``
```

No matter which of the three exponent forms is used, no quantity may represent a number greater than  $2^{63}-1$  in magnitude, nor may it have more than 3 decimal places. Numbers larger or more precise will be capped or rounded up. (E.g.: 0.1m will rounded up to 1m.) This may be extended in the future if we require larger or smaller quantities.

When a Quantity is parsed from a string, it will remember the type of suffix it had, and will use the same type again when it is serialized.

Before serializing, Quantity will be put in "canonical form". This means that Exponent/suffix will be adjusted up or down (with a corresponding increase or decrease in Mantissa) such that:

- No precision is lost
- No fractional digits will be emitted
- The exponent (or suffix) is as large as possible.

The sign will be omitted unless the number is negative.

Examples:

- 1.5 will be serialized as "1500m" - 1.5Gi will be serialized as "1536Mi"

Note that the quantity will NEVER be internally represented by a floating point number. That is the whole point of this exercise.

Non-canonical values will still parse as long as they are well formed, but will be re-emitted in their canonical form. (So always use canonical form, or don't diff.)

This format is intended to make it difficult to use these numbers without writing some sort of special handling code in the hopes that that will cause implementors to also use a fixed point implementation.

<hr>

# ResourceFieldSelector

ResourceFieldSelector represents container resources (cpu, memory) and their output format.

```
import "k8s.io/api/core/v1"
```

ResourceFieldSelector represents container resources (cpu, memory) and their output format

---

- **resource** (string), required

Required: resource to select

- **containerName** (string)

Container name: required for volumes, optional for env vars

- **divisor** ([Quantity](#))

Specifies the output format of the exposed resources, defaults to "1"

## Status

Status is a return value for calls that don't return other objects.

```
import "k8s.io/apimachinery/pkg/apis/meta/v1"
```

Status is a return value for calls that don't return other objects.

---

- **apiVersion** (string)

APIVersion defines the versioned schema of this representation of an object. Servers should convert recognized schemas to the latest internal value, and may reject unrecognized values. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#resources>

- **code** (int32)

Suggested HTTP return code for this status, 0 if not set.

- **details** (StatusDetails)

Extended data associated with the reason. Each reason may define its own extended details. This field is optional and the data returned is not guaranteed to conform to any schema except that defined by the reason type.

*StatusDetails is a set of additional properties that MAY be set by the server to provide additional information about a response. The Reason field of a Status object defines what attributes will be set. Clients must ignore fields that do not match the defined type of each attribute, and should assume that any attribute may be empty, invalid, or under defined.*

- **details.causes** ([]StatusCause)

The Causes array includes more details associated with the StatusReason failure. Not all StatusReasons may provide detailed causes.

*StatusCause provides more information about an api.Status failure, including cases when multiple errors are encountered.*

- **details.causes.field** (string)

The field of the resource that has caused this error, as named by its JSON serialization. May include dot and postfix notation for nested attributes. Arrays are zero-indexed. Fields may appear more than once in an array of causes due to fields having multiple errors. Optional.

Examples: "name" - the field "name" on the current resource "items[0].name" - the field "name" on the first array entry in "items"

- **details.causes.message** (string)

A human-readable description of the cause of the error. This field may be presented as-is to a reader.

- **details.causes.reason** (string)

A machine-readable description of the cause of the error. If this value is empty there is no information available.

- **details.group** (string)

The group attribute of the resource associated with the status StatusReason.

- **details.kind** (string)

The kind attribute of the resource associated with the status StatusReason. On some operations may differ from the requested resource Kind. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **details.name** (string)

The name attribute of the resource associated with the status StatusReason (when there is a single name which can be described).

- **details.retryAfterSeconds** (int32)

If specified, the time in seconds before the operation should be retried. Some errors may indicate the client must take an alternate action - for those errors this field may indicate how long to wait before taking the alternate action.

- **details.uid** (string)

UID of the resource. (when there is a single resource which can be described). More info: <https://kubernetes.io/docs/concepts/overview/working-with-objects/names#uids>

- **kind** (string)

Kind is a string value representing the REST resource this object represents. Servers may infer this from the endpoint the client submits requests to. Cannot be updated. In CamelCase. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **message** (string)

A human-readable description of the status of this operation.

- **metadata** ([ListMeta](#))

Standard list metadata. More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#types-kinds>

- **reason** (string)

A machine-readable description of why this operation is in the "Failure" status. If this value is empty there is no information available. A Reason clarifies an HTTP status code but does not override it.

- **status** (string)

Status of the operation. One of: "Success" or "Failure". More info: <https://git.k8s.io/community/contributors/devel/sig-architecture/api-conventions.md#spec-and-status>

## TypedLocalObjectReference

TypedLocalObjectReference contains enough information to let you locate the typed referenced object inside the same namespace.

```
import "k8s.io/api/core/v1"
```

TypedLocalObjectReference contains enough information to let you locate the typed referenced object inside the same namespace.

- 
- **kind** (string), required

Kind is the type of resource being referenced

- **name** (string), required

Name is the name of resource being referenced

- **apiGroup** (string)

APIGroup is the group for the resource being referenced. If APIGroup is not specified, the specified Kind must be in the core API group. For any other third-party types, APIGroup is required.

## Other Resources

---

# ValidatingAdmissionPolicyBindingList v1beta1

apiVersion: admissionregistration.k8s.io/v1beta1

import "k8s.io/api/admissionregistration/v1beta1"

## Common Parameters

### allowWatchBookmarks

allowWatchBookmarks requests watch events with type "BOOKMARK". Servers that do not implement bookmarks may ignore this flag and bookmarks are sent at the server's discretion. Clients should not assume bookmarks are returned at any specific interval, nor may they assume the server will send any BOOKMARK event during a session. If this is not a watch, this field is ignored.

---

### continue

The continue option should be set when retrieving more results from the server. Since this value is server defined, clients may only use the continue value from a previous query result with identical query parameters (except for the value of continue) and the server may reject a continue value it does not recognize. If the specified continue value is no longer valid whether due to expiration (generally five to fifteen minutes) or a configuration change on the server, the server will respond with a 410 ResourceExpired error together with a continue token. If the client needs a consistent list, it must restart their list without the continue field. Otherwise, the client may send another list request with the token received with the 410 error, the server will respond with a list starting from the next key, but from the latest snapshot, which is inconsistent from the previous list results - objects that are created, modified, or deleted after the first list request will be included in the response, as long as their keys are after the "next key".

This field is not supported when watch is true. Clients may start a watch from the last resourceVersion value returned by the server and not miss any modifications.

---

### dryRun

When present, indicates that modifications should not be persisted. An invalid or unrecognized dryRun directive will result in an error response and no further processing of the request. Valid values are: - All: all dry run stages will be processed

---

## fieldManager

fieldManager is a name associated with the actor or entity that is making these changes. The value must be less than or 128 characters long, and only contain printable characters, as defined by <https://pkg.go.dev/unicode#IsPrint>.

---

## fieldSelector

A selector to restrict the list of returned objects by their fields. Defaults to everything.

---

## fieldValidation

fieldValidation instructs the server on how to handle objects in the request (POST/PUT/PATCH) containing unknown or duplicate fields. Valid values are: - Ignore: This will ignore any unknown fields that are silently dropped from the object, and will ignore all but the last duplicate field that the decoder encounters. This is the default behavior prior to v1.23. - Warn: This will send a warning via the standard warning response header for each unknown field that is dropped from the object, and for each duplicate field that is encountered. The request will still succeed if there are no other errors, and will only persist the last of any duplicate fields. This is the default in v1.23+ - Strict: This will fail the request with a BadRequest error if any unknown fields would be dropped from the object, or if any duplicate fields are present. The error returned from the server will contain all unknown and duplicate fields encountered.

---

## force

Force is going to "force" Apply requests. It means user will re-acquire conflicting fields owned by other people. Force flag must be unset for non-apply patch requests.

---

## gracePeriodSeconds

The duration in seconds before the object should be deleted. Value must be non-negative integer. The value zero indicates delete immediately. If this value is nil, the default grace period for the specified type will be used. Defaults to a per object value if not specified. zero means delete immediately.

---

## labelSelector

A selector to restrict the list of returned objects by their labels. Defaults to everything.

---

## limit

limit is a maximum number of responses to return for a list call. If more items exist, the server will set the continue field on the list metadata to a value that can be used with the same initial query to retrieve the next set of results. Setting a limit may return fewer than the requested amount of items (up to zero items) in the event all requested objects are filtered out and clients should only use the presence of the continue field to determine whether more results are available. Servers may choose not to support the limit argument and will return all of the available results. If limit is specified and the continue field is empty, clients may assume that no more results are available. This field is not supported if watch is true.

The server guarantees that the objects returned when using continue will be identical to issuing a single list call without a limit - that is, no objects created, modified, or deleted after the first request is issued will be included in any subsequent continued requests. This is sometimes referred to as a consistent snapshot, and ensures that a client that is using limit to receive smaller chunks of a very large result can ensure they see all possible objects. If objects are updated during a chunked list the version of the object that was present at the time the first list result was calculated is returned.

---

## namespace

object name and auth scope, such as for teams and projects

---

## pretty

If 'true', then the output is pretty printed.

---

## propagationPolicy

Whether and how garbage collection will be performed. Either this field or OrphanDependents may be set, but not both. The default policy is decided by the existing finalizer set in the metadata.finalizers and the resource-specific default policy. Acceptable values are: 'Orphan' - orphan the dependents; 'Background' - allow the garbage collector to delete the dependents in the background; 'Foreground' - a cascading policy that deletes all dependents in the foreground.

---

## resourceVersion

resourceVersion sets a constraint on what resource versions a request may be served from. See <https://kubernetes.io/docs/reference/using-api/api-concepts/#resource-versions> for details.

Defaults to unset

---

## resourceVersionMatch

resourceVersionMatch determines how resourceVersion is applied to list calls. It is highly recommended that resourceVersionMatch be set for list calls where resourceVersion is set See <https://kubernetes.io/docs/reference/using-api/api-concepts/#resource-versions> for details.

Defaults to unset

---

## sendInitialEvents

sendInitialEvents=true may be set together with watch=true. In that case, the watch stream will begin with synthetic events to produce the current state of objects in the collection. Once all such events have been sent, a synthetic "Bookmark" event will be sent. The bookmark will report the ResourceVersion (RV) corresponding to the set of objects, and be marked with "k8s.io/initial-events-end": "true" annotation. Afterwards, the watch stream will proceed as usual, sending watch events corresponding to changes (subsequent to the RV) to objects watched.

When sendInitialEvents option is set, we require resourceVersionMatch option to also be set. The semantic of the watch request is as following: - resourceVersionMatch = NotOlderThan is interpreted as "data at least as new as the provided resourceVersion" and the bookmark event is send when the state is synced to a resourceVersion at least as fresh as the one provided by the ListOptions. If resourceVersion is unset, this is interpreted as "consistent read" and the bookmark event is send when the state is synced at least to the moment when request started being processed.

- resourceVersionMatch set to any other value or unset Invalid error is returned.

Defaults to true if resourceVersion="" or resourceVersion="0" (for backward compatibility reasons) and to false otherwise.

---

## timeoutSeconds

Timeout for the list/watch call. This limits the duration of the call, regardless of any activity or inactivity.

---

## watch

Watch for changes to the described resources and return them as a stream of add, update, and remove notifications. Specify resourceVersion.

---

## Instrumentation

---

## [CRI Pod & Container Metrics](#)

Collection of Pod & Container metrics via the CRI.

## [Node metrics data](#)

Mechanisms for accessing metrics at node, volume, pod and container level, as seen by the kubelet.

## [Kubernetes Metrics Reference](#)

Details of the metric data that Kubernetes components export.

# Kubernetes Component SLI Metrics

FEATURE STATE: Kubernetes v1.29 [stable]

By default, Kubernetes 1.30 publishes Service Level Indicator (SLI) metrics for each Kubernetes component binary. This metric endpoint is exposed on the serving HTTPS port of each component, at the path `/metrics/slis`. The ComponentSLIs [feature gate](#) defaults to enabled for each Kubernetes component as of v1.27.

## SLI Metrics

With SLI metrics enabled, each Kubernetes component exposes two metrics, labeled per healthcheck:

- a gauge (which represents the current state of the healthcheck)
- a counter (which records the cumulative counts observed for each healthcheck state)

You can use the metric information to calculate per-component availability statistics. For example, the API server checks the health of etcd. You can work out and report how available or unavailable etcd has been - as reported by its client, the API server.

The prometheus gauge data looks like this:

```
HELP kubernetes_healthcheck [ALPHA] This metric records the result of a single healthcheck.
TYPE kubernetes_healthcheck gauge
kubernetes_healthcheck{name="autoregister-completion",type="healthz"} 1
kubernetes_healthcheck{name="autoregister-completion",type="readyz"} 1
kubernetes_healthcheck{name="etcd",type="healthz"} 1
kubernetes_healthcheck{name="etcd",type="readyz"} 1
kubernetes_healthcheck{name="etcd-readiness",type="readyz"} 1
kubernetes_healthcheck{name="informer-sync",type="readyz"} 1
kubernetes_healthcheck{name="log",type="healthz"} 1
kubernetes_healthcheck{name="log",type="readyz"} 1
kubernetes_healthcheck{name="ping",type="healthz"} 1
kubernetes_healthcheck{name="ping",type="readyz"} 1
```

While the counter data looks like this:

```
HELP kubernetes_healthchecks_total [ALPHA] This metric records the results of all
healthcheck.
TYPE kubernetes_healthchecks_total counter
kubernetes_healthchecks_total{name="autoregister-completion",status="error",type="readyz"} 1
kubernetes_healthchecks_total{name="autoregister-completion",status="success",type="healthz"} 15
kubernetes_healthchecks_total{name="autoregister-completion",status="success",type="readyz"}
14
kubernetes_healthchecks_total{name="etcd",status="success",type="healthz"} 15
kubernetes_healthchecks_total{name="etcd",status="success",type="readyz"} 15
kubernetes_healthchecks_total{name="etcd-readiness",status="success",type="readyz"} 15
kubernetes_healthchecks_total{name="informer-sync",status="error",type="readyz"} 1
kubernetes_healthchecks_total{name="informer-sync",status="success",type="readyz"} 14
kubernetes_healthchecks_total{name="log",status="success",type="healthz"} 15
kubernetes_healthchecks_total{name="log",status="success",type="readyz"} 15
kubernetes_healthchecks_total{name="ping",status="success",type="healthz"} 15
kubernetes_healthchecks_total{name="ping",status="success",type="readyz"} 15
```

## Using this data

The component SLIs metrics endpoint is intended to be scraped at a high frequency. Scraping at a high frequency means that you end up with greater granularity of the gauge's signal, which can be then used to calculate SLOs. The `/metrics/slis` endpoint provides the raw data necessary to calculate an availability SLO for the respective Kubernetes component.

# CRI Pod & Container Metrics

Collection of Pod & Container metrics via the CRI.  
FEATURE STATE: Kubernetes v1.23 [alpha]

The [kubelet](#) collects pod and container metrics via [cAdvisor](#). As an alpha feature, Kubernetes lets you configure the collection of pod and container metrics via the [Container Runtime Interface](#) (CRI). You must enable the `PodAndContainerStatsFromCRI` [feature gate](#) and use a compatible CRI implementation (containerd  $\geq$  1.6.0, CRI-O  $\geq$  1.23.0) to use the CRI based collection mechanism.

## CRI Pod & Container Metrics

With `PodAndContainerStatsFromCRI` enabled, the kubelet polls the underlying container runtime for pod and container stats instead of inspecting the host system directly using cAdvisor. The benefits of relying on the container runtime for this information as opposed to direct collection with cAdvisor include:

- Potential improved performance if the container runtime already collects this information during normal operations. In this case, the data can be re-used instead of being aggregated again by the kubelet.
- It further decouples the kubelet and the container runtime allowing collection of metrics for container runtimes that don't run processes directly on the host with kubelet where they are observable by cAdvisor (for example: container runtimes that use virtualization).

# Node metrics data

Mechanisms for accessing metrics at node, volume, pod and container level, as seen by the kubelet.

The [kubelet](#) gathers metric statistics at the node, volume, pod and container level, and emits this information in the [Summary API](#).

You can send a proxied request to the stats summary API via the Kubernetes API server.

Here is an example of a Summary API request for a node named minikube:

```
kubectl get --raw "/api/v1/nodes/minikube/proxy/stats/summary"
```

Here is the same API call using curl:

```
You need to run "kubectl proxy" first
Change 8080 to the port that "kubectl proxy" assigns
curl http://localhost:8080/api/v1/nodes/minikube/proxy/stats/summary
```

## Note:

Beginning with metrics-server 0.6.x, metrics-server queries the /metrics/resource kubelet endpoint, and not /stats/summary.

## Summary metrics API source

By default, Kubernetes fetches node summary metrics data using an embedded [cAdvisor](#) that runs within the kubelet. If you enable the PodAndContainerStatsFromCRI [feature gate](#) in your cluster, and you use a container runtime that supports statistics access via [Container Runtime Interface](#) (CRI), then the kubelet [fetches Pod- and container-level metric data using CRI](#), and not via cAdvisor.

## What's next

The task pages for [Troubleshooting Clusters](#) discuss how to use a metrics pipeline that rely on these data.

# Kubernetes Metrics Reference

Details of the metric data that Kubernetes components export.

## Metrics (v1.30)

This page details the metrics that different Kubernetes components export. You can query the metrics endpoint for these components using an HTTP scrape, and fetch the current metrics data in Prometheus format.

## List of Stable Kubernetes Metrics

Stable metrics observe strict API contracts and no labels can be added or removed from stable metrics during their lifetime.

`apiserver_admission_controller_admission_duration_seconds`

Admission controller latency histogram in seconds, identified by name and broken out for each operation and API resource and type (validate or admit).

- Stability Level:STABLE
- Type: Histogram
- Labels:nameoperationrejectedtype

`apiserver_admission_step_admission_duration_seconds`

Admission sub-step latency histogram in seconds, broken out for each operation and API resource and step type (validate or admit).

- Stability Level:STABLE
- Type: Histogram
- Labels:operationrejectedtype

`apiserver_admission_webhook_admission_duration_seconds`

Admission webhook latency histogram in seconds, identified by name and broken out for each operation and API resource and type (validate or admit).

- Stability Level:STABLE
- Type: Histogram
- Labels:nameoperationrejectedtype

`apiserver_current_inflight_requests`

Maximal number of currently used inflight request limit of this apiserver per request kind in last second.

- Stability Level:STABLE
- Type: Gauge
- Labels:request\_kind

`apiserver_longrunning_requests`

Gauge of all active long-running apiserver requests broken out by verb, group, version, resource, scope and component. Not all requests are tracked this way.

- Stability Level:STABLE
- Type: Gauge
- Labels:componentgroupresourcescopesubresourceverbversion

`apiserver_requested_deprecated_apis`

Gauge of deprecated APIs that have been requested, broken out by API group, version, resource, subresource, and removed\_release.

- Stability Level:STABLE
- Type: Gauge
- Labels:groupremoved\_releaseresourcesubresourceversion

`apiserver_response_sizes`

Response size distribution in bytes for each group, version, verb, resource, subresource, scope and component.

- Stability Level:STABLE
- Type: Histogram
- Labels:componentgroupresourcescopesubresourceverbversion

apiserver\_storage\_objects

Number of stored objects at the time of last check split by kind. In case of a fetching error, the value will be -1.

- Stability Level:STABLE
- Type: Gauge
- Labels:resource

apiserver\_storage\_size\_bytes

Size of the storage database file physically allocated in bytes.

- Stability Level:STABLE
- Type: Custom
- Labels:storage\_cluster\_id

container\_cpu\_usage\_seconds\_total

Cumulative cpu time consumed by the container in core-seconds

- Stability Level:STABLE
- Type: Custom
- Labels:containerpodnamespace

container\_memory\_working\_set\_bytes

Current working set of the container in bytes

- Stability Level:STABLE
- Type: Custom
- Labels:containerpodnamespace

container\_start\_time\_seconds

Start time of the container since unix epoch in seconds

- Stability Level:STABLE
- Type: Custom
- Labels:containerpodnamespace

cronjob\_controller\_job\_creation\_skew\_duration\_seconds

Time between when a cronjob is scheduled to be run, and when the corresponding job is created

- Stability Level:STABLE
- Type: Histogram

job\_controller\_job\_pods\_finished\_total

The number of finished Pods that are fully tracked

- Stability Level:STABLE
- Type: Counter

- Labels:completion\_moderesult

job\_controller\_job\_sync\_duration\_seconds

The time it took to sync a job

- Stability Level:STABLE
- Type: Histogram
- Labels:actioncompletion\_moderesult

job\_controller\_job\_syncs\_total

The number of job syncs

- Stability Level:STABLE
- Type: Counter
- Labels:actioncompletion\_moderesult

job\_controller\_jobs\_finished\_total

The number of finished jobs

- Stability Level:STABLE
- Type: Counter
- Labels:completion\_modereasonresult

kube\_pod\_resource\_limit

Resources limit for workloads on the cluster, broken down by pod. This shows the resource usage the scheduler and kubelet expect per pod for resources along with the unit for the resource if any.

- Stability Level:STABLE
- Type: Custom
- Labels:namespacepodnodeschedulerpriorityresourceunit

kube\_pod\_resource\_request

Resources requested by workloads on the cluster, broken down by pod. This shows the resource usage the scheduler and kubelet expect per pod for resources along with the unit for the resource if any.

- Stability Level:STABLE
- Type: Custom
- Labels:namespacepodnodeschedulerpriorityresourceunit

kubernetes\_healthcheck

This metric records the result of a single healthcheck.

- Stability Level:STABLE
- Type: Gauge
- Labels:nametype

kubernetes\_healthchecks\_total

This metric records the results of all healthcheck.

- Stability Level:STABLE
- Type: Counter
- Labels:nameinstancetype

node\_collector\_evictions\_total

Number of Node evictions that happened since current instance of NodeController started.

- Stability Level:STABLE
- Type: Counter
- Labels:zone

node\_cpu\_usage\_seconds\_total

Cumulative cpu time consumed by the node in core-seconds

- Stability Level:STABLE
- Type: Custom

node\_memory\_working\_set\_bytes

Current working set of the node in bytes

- Stability Level:STABLE
- Type: Custom

pod\_cpu\_usage\_seconds\_total

Cumulative cpu time consumed by the pod in core-seconds

- Stability Level:STABLE
- Type: Custom
- Labels:podnamespace

pod\_memory\_working\_set\_bytes

Current working set of the pod in bytes

- Stability Level:STABLE
- Type: Custom
- Labels:podnamespace

resource\_scrape\_error

1 if there was an error while getting container metrics, 0 otherwise

- Stability Level:STABLE
- Type: Custom

scheduler\_framework\_extension\_point\_duration\_seconds

Latency for running all plugins of a specific extension point.

- Stability Level:STABLE
- Type: Histogram
- Labels:extension\_pointprofilestatus

scheduler\_pending\_pods

Number of pending pods, by the queue type. 'active' means number of pods in activeQ; 'backoff' means number of pods in backoffQ; 'unschedulable' means number of pods in unschedulablePods that the scheduler attempted to schedule and failed; 'gated' is the number of unschedulable pods that the scheduler never attempted to schedule because they are gated.

- Stability Level:STABLE
- Type: Gauge
- Labels:queue

scheduler\_pod\_scheduling\_attempts

Number of attempts to successfully schedule a pod.

- Stability Level:STABLE
- Type: Histogram

scheduler\_pod\_scheduling\_duration\_seconds

E2e latency for a pod being scheduled which may include multiple scheduling attempts.

- Stability Level:STABLE
- Type: Histogram
- Labels:attempts
- Deprecated Versions:1.29.0

scheduler\_preemption\_attempts\_total

Total preemption attempts in the cluster till now

- Stability Level:STABLE
- Type: Counter

scheduler\_preemption\_victims

Number of selected preemption victims

- Stability Level:STABLE
- Type: Histogram

scheduler\_queue\_incoming\_pods\_total

Number of pods added to scheduling queues by event and queue type.

- Stability Level:STABLE
- Type: Counter
- Labels:eventqueue

scheduler\_schedule\_attempts\_total

Number of attempts to schedule pods, by the result. 'unschedulable' means a pod could not be scheduled, while 'error' means an internal scheduler problem.

- Stability Level:STABLE
- Type: Counter
- Labels:profileresult

scheduler\_scheduling\_attempt\_duration\_seconds

Scheduling attempt latency in seconds (scheduling algorithm + binding)

- Stability Level:STABLE
- Type: Histogram
- Labels:profileresult

## List of Beta Kubernetes Metrics

Beta metrics observe a looser API contract than its stable counterparts. No labels can be removed from beta metrics during their lifetime, however, labels can be added while the metric is in the beta stage. This offers the assurance that beta metrics will honor existing dashboards and alerts, while allowing for amendments in the future.

apiserver\_flowcontrol\_current\_executing\_requests

Number of requests in initial (for a WATCH) or any (for a non-WATCH) execution stage in the API Priority and Fairness subsystem

- Stability Level: BETA
- Type: Gauge
- Labels: flow\_schemapriority\_level

apiserver\_flowcontrol\_current\_executing\_seats

Concurrency (number of seats) occupied by the currently executing (initial stage for a WATCH, any stage otherwise) requests in the API Priority and Fairness subsystem

- Stability Level: BETA
- Type: Gauge
- Labels: flow\_schemapriority\_level

apiserver\_flowcontrol\_current\_inqueue\_requests

Number of requests currently pending in queues of the API Priority and Fairness subsystem

- Stability Level: BETA
- Type: Gauge
- Labels: flow\_schemapriority\_level

apiserver\_flowcontrol\_dispatched\_requests\_total

Number of requests executed by API Priority and Fairness subsystem

- Stability Level: BETA
- Type: Counter
- Labels: flow\_schemapriority\_level

apiserver\_flowcontrol\_nominal\_limit\_seats

Nominal number of execution seats configured for each priority level

- Stability Level: BETA
- Type: Gauge
- Labels: priority\_level

apiserver\_flowcontrol\_rejected\_requests\_total

Number of requests rejected by API Priority and Fairness subsystem

- Stability Level: BETA
- Type: Counter
- Labels: flow\_schemapriority\_levelreason

apiserver\_flowcontrol\_request\_wait\_duration\_seconds

Length of time a request spent waiting in its queue

- Stability Level: BETA
- Type: Histogram
- Labels: executeflow\_schemapriority\_level

disabled\_metrics\_total

The count of disabled metrics.

- Stability Level: BETA

- Type: Counter

hidden\_metrics\_total

The count of hidden metrics.

- Stability Level: BETA
- Type: Counter

kubernetes\_feature\_enabled

This metric records the data about the stage and enablement of a k8s feature.

- Stability Level: BETA
- Type: Gauge
- Labels: name, stage

registered\_metrics\_total

The count of registered metrics broken by stability level and deprecation version.

- Stability Level: BETA
- Type: Counter
- Labels: deprecated\_version, stability\_level

scheduler\_pod\_scheduling\_sli\_duration\_seconds

E2e latency for a pod being scheduled, from the time the pod enters the scheduling queue and might involve multiple scheduling attempts.

- Stability Level: BETA
- Type: Histogram
- Labels: attempts

## List of Alpha Kubernetes Metrics

Alpha metrics do not have any API guarantees. These metrics must be used at your own risk, subsequent versions of Kubernetes may remove these metrics altogether, or mutate the API in such a way that breaks existing dashboards and alerts.

aggregator\_discovery\_aggregation\_count\_total

Counter of number of times discovery was aggregated

- Stability Level: ALPHA
- Type: Counter

aggregator\_openapi\_v2\_regeneration\_count

Counter of OpenAPI v2 spec regeneration count broken down by causing API Service name and reason.

- Stability Level: ALPHA
- Type: Counter
- Labels: apiservice, reason

aggregator\_openapi\_v2\_regeneration\_duration

Gauge of OpenAPI v2 spec regeneration duration in seconds.

- Stability Level: ALPHA

- Type: Gauge
- Labels:reason

aggregator\_unavailable\_apiservice

Gauge of APIServices which are marked as unavailable broken down by APIService name.

- Stability Level:ALPHA
- Type: Custom
- Labels:name

aggregator\_unavailable\_apiservice\_total

Counter of APIServices which are marked as unavailable broken down by APIService name and reason.

- Stability Level:ALPHA
- Type: Counter
- Labels:namereason

apiextensions\_apiserver\_validation\_ratcheting\_seconds

Time for comparison of old to new for the purposes of CRDValidationRatcheting during an UPDATE in seconds.

- Stability Level:ALPHA
- Type: Histogram

apiextensions\_openapi\_v2\_regeneration\_count

Counter of OpenAPI v2 spec regeneration count broken down by causing CRD name and reason.

- Stability Level:ALPHA
- Type: Counter
- Labels:crdreason

apiextensions\_openapi\_v3\_regeneration\_count

Counter of OpenAPI v3 spec regeneration count broken down by group, version, causing CRD and reason.

- Stability Level:ALPHA
- Type: Counter
- Labels:crdgroupreasonversion

apiserver\_admission\_match\_condition\_evaluation\_errors\_total

Admission match condition evaluation errors count, identified by name of resource containing the match condition and broken out for each kind containing matchConditions (webhook or policy), operation and admission type (validate or admit).

- Stability Level:ALPHA
- Type: Counter
- Labels:kindnameoperationtype

apiserver\_admission\_match\_condition\_evaluation\_seconds

Admission match condition evaluation time in seconds, identified by name and broken out for each kind containing matchConditions (webhook or policy), operation and type (validate or admit).

- Stability Level:ALPHA
- Type: Histogram
- Labels:kindnameoperationtype

apiserver\_admission\_match\_condition\_exclusions\_total

Admission match condition evaluation exclusions count, identified by name of resource containing the match condition and broken out for each kind containing matchConditions (webhook or policy), operation and admission type (validate or admit).

- Stability Level:ALPHA
- Type: Counter
- Labels:kindnameoperationtype

apiserver\_admission\_step\_admission\_duration\_seconds\_summary

Admission sub-step latency summary in seconds, broken out for each operation and API resource and step type (validate or admit).

- Stability Level:ALPHA
- Type: Summary
- Labels:operationrejectedtype

apiserver\_admission\_webhook\_fail\_open\_count

Admission webhook fail open count, identified by name and broken out for each admission type (validating or mutating).

- Stability Level:ALPHA
- Type: Counter
- Labels:nametype

apiserver\_admission\_webhook\_rejection\_count

Admission webhook rejection count, identified by name and broken out for each admission type (validating or admit) and operation. Additional labels specify an error type (calling\_webhook\_error or apiserver\_internal\_error if an error occurred; no\_error otherwise) and optionally a non-zero rejection code if the webhook rejects the request with an HTTP status code (honored by the apiserver when the code is greater or equal to 400). Codes greater than 600 are truncated to 600, to keep the metrics cardinality bounded.

- Stability Level:ALPHA
- Type: Counter
- Labels:error\_typeoperationrejection\_codetype

apiserver\_admission\_webhook\_request\_total

Admission webhook request total, identified by name and broken out for each admission type (validating or mutating) and operation. Additional labels specify whether the request was rejected or not and an HTTP status code. Codes greater than 600 are truncated to 600, to keep the metrics cardinality bounded.

- Stability Level:ALPHA
- Type: Counter
- Labels:codenameoperationrejectedtype

apiserver\_audit\_error\_total

Counter of audit events that failed to be audited properly. Plugin identifies the plugin affected by the error.

- Stability Level:ALPHA
- Type: Counter
- Labels:plugin

apiserver\_audit\_event\_total

Counter of audit events generated and sent to the audit backend.

- Stability Level:ALPHA
- Type: Counter

apiserver\_audit\_level\_total

Counter of policy levels for audit events (1 per request).

- Stability Level:ALPHA
- Type: Counter
- Labels:level

apiserver\_audit\_requests\_rejected\_total

Counter of apiserver requests rejected due to an error in audit logging backend.

- Stability Level:ALPHA
- Type: Counter

apiserver\_authentication\_config\_controller\_automatic\_reload\_last\_timestamp\_seconds

Timestamp of the last automatic reload of authentication configuration split by status and apiserver identity.

- Stability Level:ALPHA
- Type: Gauge
- Labels:apiserver\_id\_hashstatus

apiserver\_authentication\_config\_controller\_automatic\_reloads\_total

Total number of automatic reloads of authentication configuration split by status and apiserver identity.

- Stability Level:ALPHA
- Type: Counter
- Labels:apiserver\_id\_hashstatus

apiserver\_authentication\_jwt\_authenticator\_latency\_seconds

Latency of jwt authentication operations in seconds. This is the time spent authenticating a token for cache miss only (i.e. when the token is not found in the cache).

- Stability Level:ALPHA
- Type: Histogram
- Labels:jwt\_issuer\_hashresult

apiserver\_authorization\_decisions\_total

Total number of terminal decisions made by an authorizer split by authorizer type, name, and decision.

- Stability Level:ALPHA
- Type: Counter
- Labels:decisionnametype

apiserver\_authorization\_match\_condition\_evaluation\_errors\_total

Total number of errors when an authorization webhook encounters a match condition error split by authorizer type and name.

- Stability Level:ALPHA
- Type: Counter
- Labels:nametype

apiserver\_authorization\_match\_condition\_evaluation\_seconds

Authorization match condition evaluation time in seconds, split by authorizer type and name.

- Stability Level:ALPHA
- Type: Histogram
- Labels:nametype

apiserver\_authorization\_match\_condition\_exclusions\_total

Total number of exclusions when an authorization webhook is skipped because match conditions exclude it.

- Stability Level:ALPHA
- Type: Counter
- Labels:nametype

apiserver\_authorization\_webhook\_duration\_seconds

Request latency in seconds.

- Stability Level:ALPHA
- Type: Histogram
- Labels:nameresult

apiserver\_authorization\_webhook\_evaluations\_fail\_open\_total

NoOpinion results due to webhook timeout or error.

- Stability Level:ALPHA
- Type: Counter
- Labels:nameresult

apiserver\_authorization\_webhook\_evaluations\_total

Round-trips to authorization webhooks.

- Stability Level:ALPHA
- Type: Counter
- Labels:nameresult

apiserver\_cache\_list\_fetched\_objects\_total

Number of objects read from watch cache in the course of serving a LIST request

- Stability Level:ALPHA

- Type: Counter
- Labels:indexresource\_prefix

apiserver\_cache\_list\_returned\_objects\_total

Number of objects returned for a LIST request from watch cache

- Stability Level:ALPHA
- Type: Counter
- Labels:resource\_prefix

apiserver\_cache\_list\_total

Number of LIST requests served from watch cache

- Stability Level:ALPHA
- Type: Counter
- Labels:indexresource\_prefix

apiserver\_cel\_compilation\_duration\_seconds

CEL compilation time in seconds.

- Stability Level:ALPHA
- Type: Histogram

apiserver\_cel\_evaluation\_duration\_seconds

CEL evaluation time in seconds.

- Stability Level:ALPHA
- Type: Histogram

apiserver\_certificates\_registry\_csr\_honored\_duration\_total

Total number of issued CSRs with a requested duration that was honored, sliced by signer (only kubernetes.io signer names are specifically identified)

- Stability Level:ALPHA
- Type: Counter
- Labels:signerName

apiserver\_certificates\_registry\_csr\_requested\_duration\_total

Total number of issued CSRs with a requested duration, sliced by signer (only kubernetes.io signer names are specifically identified)

- Stability Level:ALPHA
- Type: Counter
- Labels:signerName

apiserver\_client\_certificate\_expiration\_seconds

Distribution of the remaining lifetime on the certificate used to authenticate a request.

- Stability Level:ALPHA
- Type: Histogram

apiserver\_clusterip\_repair\_ip\_errors\_total

Number of errors detected on clusterips by the repair loop broken down by type of error: leak, repair, full, outOfRange, duplicate, unknown, invalid

- Stability Level:ALPHA
- Type: Counter
- Labels:type

apiserver\_clusterip\_repair\_reconcile\_errors\_total

Number of reconciliation failures on the clusterip repair reconcile loop

- Stability Level:ALPHA
- Type: Counter

apiserver\_conversion\_webhook\_duration\_seconds

Conversion webhook request latency

- Stability Level:ALPHA
- Type: Histogram
- Labels:failure\_typeresult

apiserver\_conversion\_webhook\_request\_total

Counter for conversion webhook requests with success/failure and failure error type

- Stability Level:ALPHA
- Type: Counter
- Labels:failure\_typeresult

apiserver\_crd\_conversion\_webhook\_duration\_seconds

CRD webhook conversion duration in seconds

- Stability Level:ALPHA
- Type: Histogram
- Labels:crd\_namefrom\_versionsucceededto\_version

apiserver\_current\_inqueue\_requests

Maximal number of queued requests in this apiserver per request kind in last second.

- Stability Level:ALPHA
- Type: Gauge
- Labels:request\_kind

apiserver\_delegated\_authn\_request\_duration\_seconds

Request latency in seconds. Broken down by status code.

- Stability Level:ALPHA
- Type: Histogram
- Labels:code

apiserver\_delegated\_authn\_request\_total

Number of HTTP requests partitioned by status code.

- Stability Level:ALPHA
- Type: Counter
- Labels:code

apiserver\_delegated\_authz\_request\_duration\_seconds  
Request latency in seconds. Broken down by status code.

- Stability Level:ALPHA
- Type: Histogram
- Labels:code

apiserver\_delegated\_authz\_request\_total  
Number of HTTP requests partitioned by status code.

- Stability Level:ALPHA
- Type: Counter
- Labels:code

apiserver\_egress\_dialer\_dial\_duration\_seconds  
Dial latency histogram in seconds, labeled by the protocol (http-connect or grpc), transport (tcp or uds)

- Stability Level:ALPHA
- Type: Histogram
- Labels:protocoltransport

apiserver\_egress\_dialer\_dial\_failure\_count  
Dial failure count, labeled by the protocol (http-connect or grpc), transport (tcp or uds), and stage (connect or proxy). The stage indicates at which stage the dial failed

- Stability Level:ALPHA
- Type: Counter
- Labels:protocolstagetransport

apiserver\_egress\_dialer\_dial\_start\_total  
Dial starts, labeled by the protocol (http-connect or grpc) and transport (tcp or uds).

- Stability Level:ALPHA
- Type: Counter
- Labels:protocoltransport

apiserver\_encryption\_config\_controller\_automatic\_reload\_failures\_total  
Total number of failed automatic reloads of encryption configuration split by apiserver identity.

- Stability Level:ALPHA
- Type: Counter
- Labels:apiserver\_id\_hash
- Deprecated Versions:1.30.0

apiserver\_encryption\_config\_controller\_automatic\_reload\_success\_total  
Total number of successful automatic reloads of encryption configuration split by apiserver identity.

- Stability Level:ALPHA
- Type: Counter
- Labels:apiserver\_id\_hash
- Deprecated Versions:1.30.0

apiserver\_envelope\_encryption\_dek\_cache\_fill\_percent

Percent of the cache slots currently occupied by cached DEKs.

- Stability Level:ALPHA
- Type: Gauge

apiserver\_envelope\_encryption\_dek\_cache\_inter\_arrival\_time\_seconds  
Time (in seconds) of inter arrival of transformation requests.

- Stability Level:ALPHA
- Type: Histogram
- Labels:transformation\_type

apiserver\_envelope\_encryption\_dek\_source\_cache\_size  
Number of records in data encryption key (DEK) source cache. On a restart, this value is an approximation of the number of decrypt RPC calls the server will make to the KMS plugin.

- Stability Level:ALPHA
- Type: Gauge
- Labels:provider\_name

apiserver\_envelope\_encryption\_invalid\_key\_id\_from\_status\_total  
Number of times an invalid keyID is returned by the Status RPC call split by error.

- Stability Level:ALPHA
- Type: Counter
- Labels:errorprovider\_name

apiserver\_envelope\_encryption\_key\_id\_hash\_last\_timestamp\_seconds  
The last time in seconds when a keyID was used.

- Stability Level:ALPHA
- Type: Gauge
- Labels:apiserver\_id\_hashkey\_id\_hashprovider\_namestransformation\_type

apiserver\_envelope\_encryption\_key\_id\_hash\_status\_last\_timestamp\_seconds  
The last time in seconds when a keyID was returned by the Status RPC call.

- Stability Level:ALPHA
- Type: Gauge
- Labels:apiserver\_id\_hashkey\_id\_hashprovider\_name

apiserver\_envelope\_encryption\_key\_id\_hash\_total  
Number of times a keyID is used split by transformation type, provider, and apiserver identity.

- Stability Level:ALPHA
- Type: Counter
- Labels:apiserver\_id\_hashkey\_id\_hashprovider\_namestransformation\_type

apiserver\_envelope\_encryption\_kms\_operations\_latency\_seconds  
KMS operation duration with gRPC error code status total.

- Stability Level:ALPHA
- Type: Histogram
- Labels:grpc\_status\_codemethod\_nameprovider\_name

apiserver\_flowcontrol\_current\_inqueue\_seats

Number of seats currently pending in queues of the API Priority and Fairness subsystem

- Stability Level:ALPHA
- Type: Gauge
- Labels:flow\_schemapriority\_level

apiserver\_flowcontrol\_current\_limit\_seats

current derived number of execution seats available to each priority level

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_current\_r

R(time of last change)

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_demand\_seats

Observations, at the end of every nanosecond, of (the number of seats each priority level could use) / (nominal number of seats for that level)

- Stability Level:ALPHA
- Type: TimingRatioHistogram
- Labels:priority\_level

apiserver\_flowcontrol\_demand\_seats\_average

Time-weighted average, over last adjustment period, of demand\_seats

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_demand\_seats\_high\_watermark

High watermark, over last adjustment period, of demand\_seats

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_demand\_seats\_smoothed

Smoothed seat demands

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_demand\_seats\_stddev

Time-weighted standard deviation, over last adjustment period, of demand\_seats

- Stability Level:ALPHA
- Type: Gauge

- Labels:priority\_level

apiserver\_flowcontrol\_dispatch\_r  
R(time of last dispatch)

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_epoch\_advance\_total  
Number of times the queueset's progress meter jumped backward

- Stability Level:ALPHA
- Type: Counter
- Labels:priority\_levelsuccess

apiserver\_flowcontrol\_latest\_s  
S(most recently dispatched request)

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_lower\_limit\_seats  
Configured lower bound on number of execution seats available to each priority level

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_next\_discounted\_s\_bounds  
min and max, over queues, of S(oldest waiting request in queue) - estimated work in progress

- Stability Level:ALPHA
- Type: Gauge
- Labels:boundpriority\_level

apiserver\_flowcontrol\_next\_s\_bounds  
min and max, over queues, of S(oldest waiting request in queue)

- Stability Level:ALPHA
- Type: Gauge
- Labels:boundpriority\_level

apiserver\_flowcontrol\_priority\_level\_request\_utilization  
Observations, at the end of every nanosecond, of number of requests (as a fraction of the relevant limit) waiting or in any stage of execution (but only initial stage for WATCHes)

- Stability Level:ALPHA
- Type: TimingRatioHistogram
- Labels:phasepriority\_level

apiserver\_flowcontrol\_priority\_level\_seat\_utilization

Observations, at the end of every nanosecond, of utilization of seats for any stage of execution (but only initial stage for WATCHes)

- Stability Level:ALPHA
- Type: TimingRatioHistogram
- Labels:priority\_level
- Const Labels:phase:executing

apiserver\_flowcontrol\_read\_vs\_write\_current\_requests

Observations, at the end of every nanosecond, of the number of requests (as a fraction of the relevant limit) waiting or in regular stage of execution

- Stability Level:ALPHA
- Type: TimingRatioHistogram
- Labels:phaserequest\_kind

apiserver\_flowcontrol\_request\_concurrency\_in\_use

Concurrency (number of seats) occupied by the currently executing (initial stage for a WATCH, any stage otherwise) requests in the API Priority and Fairness subsystem

- Stability Level:ALPHA
- Type: Gauge
- Labels:flow\_schemapriority\_level
- Deprecated Versions:1.31.0

apiserver\_flowcontrol\_request\_concurrency\_limit

Nominal number of execution seats configured for each priority level

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level
- Deprecated Versions:1.30.0

apiserver\_flowcontrol\_request\_dispatch\_no\_accommodation\_total

Number of times a dispatch attempt resulted in a non accommodation due to lack of available seats

- Stability Level:ALPHA
- Type: Counter
- Labels:flow\_schemapriority\_level

apiserver\_flowcontrol\_request\_execution\_seconds

Duration of initial stage (for a WATCH) or any (for a non-WATCH) stage of request execution in the API Priority and Fairness subsystem

- Stability Level:ALPHA
- Type: Histogram
- Labels:flow\_schemapriority\_leveltype

apiserver\_flowcontrol\_request\_queue\_length\_after\_enqueue

Length of queue in the API Priority and Fairness subsystem, as seen by each request after it is enqueued

- Stability Level:ALPHA

- Type: Histogram
- Labels:flow\_schemapriority\_level

apiserver\_flowcontrol\_seat\_fair\_frac

Fair fraction of server's concurrency to allocate to each priority level that can use it

- Stability Level:ALPHA
- Type: Gauge

apiserver\_flowcontrol\_target\_seats

Seat allocation targets

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_upper\_limit\_seats

Configured upper bound on number of execution seats available to each priority level

- Stability Level:ALPHA
- Type: Gauge
- Labels:priority\_level

apiserver\_flowcontrol\_watch\_count\_samples

count of watchers for mutating requests in API Priority and Fairness

- Stability Level:ALPHA
- Type: Histogram
- Labels:flow\_schemapriority\_level

apiserver\_flowcontrol\_work\_estimated\_seats

Number of estimated seats (maximum of initial and final seats) associated with requests in API Priority and Fairness

- Stability Level:ALPHA
- Type: Histogram
- Labels:flow\_schemapriority\_level

apiserver\_init\_events\_total

Counter of init events processed in watch cache broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_kube\_aggregator\_x509\_insecure\_sha1\_total

Counts the number of requests to servers with insecure SHA1 signatures in their serving certificate OR the number of connection failures due to the insecure SHA1 signatures (either/or, based on the runtime environment)

- Stability Level:ALPHA
- Type: Counter

apiserver\_kube\_aggregator\_x509\_missing\_san\_total

Counts the number of requests to servers missing SAN extension in their serving certificate OR the number of connection failures due to the lack of x509 certificate SAN extension missing (either/or, based on the runtime environment)

- Stability Level:ALPHA
- Type: Counter

apiserver\_nodeport\_repair\_port\_errors\_total

Number of errors detected on ports by the repair loop broken down by type of error: leak, repair, full, outOfRange, duplicate, unknown

- Stability Level:ALPHA
- Type: Counter
- Labels:type

apiserver\_request\_aborts\_total

Number of requests which apiserver aborted possibly due to a timeout, for each group, version, verb, resource, subresource and scope

- Stability Level:ALPHA
- Type: Counter
- Labels:groupresourcescopesubresourceverbversion

apiserver\_request\_body\_size\_bytes

Apiserver request body size in bytes broken out by resource and verb.

- Stability Level:ALPHA
- Type: Histogram
- Labels:resourceverb

apiserver\_request\_filter\_duration\_seconds

Request filter latency distribution in seconds, for each filter type

- Stability Level:ALPHA
- Type: Histogram
- Labels:filter

apiserver\_request\_post\_timeout\_total

Tracks the activity of the request handlers after the associated requests have been timed out by the apiserver

- Stability Level:ALPHA
- Type: Counter
- Labels:sourcestatus

apiserver\_request\_sli\_duration\_seconds

Response latency distribution (not counting webhook duration and priority & fairness queue wait times) in seconds for each verb, group, version, resource, subresource, scope and component.

- Stability Level:ALPHA
- Type: Histogram
- Labels:componentgroupresourcescopesubresourceverbversion

apiserver\_request\_slo\_duration\_seconds

Response latency distribution (not counting webhook duration and priority & fairness queue wait times) in seconds for each verb, group, version, resource, subresource, scope and component.

- Stability Level:ALPHA
- Type: Histogram
- Labels:componentgroupresourcescopesubresourceverbversion
- Deprecated Versions:1.27.0

apiserver\_request\_terminations\_total

Number of requests which apiserver terminated in self-defense.

- Stability Level:ALPHA
- Type: Counter
- Labels:codecomponentgroupresourcescopesubresourceverbversion

apiserver\_request\_timestamp\_comparison\_time

Time taken for comparison of old vs new objects in UPDATE or PATCH requests

- Stability Level:ALPHA
- Type: Histogram
- Labels:code\_path

apiserver\_rerouted\_request\_total

Total number of requests that were proxied to a peer kube apiserver because the local apiserver was not capable of serving it

- Stability Level:ALPHA
- Type: Counter
- Labels:code

apiserver\_selfrequest\_total

Counter of apiserver self-requests broken out for each verb, API resource and subresource.

- Stability Level:ALPHA
- Type: Counter
- Labels:resourcesubresourceverb

apiserver\_storage\_data\_key\_generation\_duration\_seconds

Latencies in seconds of data encryption key(DEK) generation operations.

- Stability Level:ALPHA
- Type: Histogram

apiserver\_storage\_data\_key\_generation\_failures\_total

Total number of failed data encryption key(DEK) generation operations.

- Stability Level:ALPHA
- Type: Counter

apiserver\_storage\_db\_total\_size\_in\_bytes

Total size of the storage database file physically allocated in bytes.

- Stability Level:ALPHA
- Type: Gauge

- Labels:endpoint
- Deprecated Versions:1.28.0

apiserver\_storage\_decode\_errors\_total

Number of stored object decode errors split by object type

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_envelope\_transformation\_cache\_misses\_total

Total number of cache misses while accessing key decryption key(KEK).

- Stability Level:ALPHA
- Type: Counter

apiserver\_storage\_events\_received\_total

Number of etcd events received split by kind.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_list\_evaluated\_objects\_total

Number of objects tested in the course of serving a LIST request from storage

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_list\_fetched\_objects\_total

Number of objects read from storage in the course of serving a LIST request

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_list\_returned\_objects\_total

Number of objects returned for a LIST request from storage

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_list\_total

Number of LIST requests served from storage

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_storage\_transformation\_duration\_seconds

Latencies in seconds of value transformation operations.

- Stability Level:ALPHA

- Type: Histogram
- Labels: transformation\_type transformer\_prefix

apiserver\_storage\_transformation\_operations\_total

Total number of transformations. Successful transformation will have a status 'OK' and a varied status string when the transformation fails. This status and transformation\_type fields may be used for alerting on encryption/decryption failure using transformation\_type from\_storage for decryption and to\_storage for encryption

- Stability Level: ALPHA
- Type: Counter
- Labels: status transformation\_type transformer\_prefix

apiserver\_stream\_translator\_requests\_total

Total number of requests that were handled by the StreamTranslatorProxy, which processes streaming RemoteCommand/V5

- Stability Level: ALPHA
- Type: Counter
- Labels: code

apiserver\_terminated\_watchers\_total

Counter of watchers closed due to unresponsiveness broken by resource type.

- Stability Level: ALPHA
- Type: Counter
- Labels: resource

apiserver\_tls\_handshake\_errors\_total

Number of requests dropped with 'TLS handshake error from' error

- Stability Level: ALPHA
- Type: Counter

apiserver\_validating\_admission\_policy\_check\_duration\_seconds

Validation admission latency for individual validation expressions in seconds, labeled by policy and further including binding, state and enforcement action taken.

- Stability Level: ALPHA
- Type: Histogram
- Labels: enforcement\_action policy policy\_binding state

apiserver\_validating\_admission\_policy\_check\_total

Validation admission policy check total, labeled by policy and further identified by binding, enforcement action taken, and state.

- Stability Level: ALPHA
- Type: Counter
- Labels: enforcement\_action policy policy\_binding state

apiserver\_validating\_admission\_policy\_definition\_total

Validation admission policy count total, labeled by state and enforcement action.

- Stability Level: ALPHA
- Type: Counter

- Labels:enforcement\_actionstate

apiserver\_watch\_cache\_events\_dispatched\_total

Counter of events dispatched in watch cache broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_watch\_cache\_events\_received\_total

Counter of events received in watch cache broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_watch\_cache\_initializations\_total

Counter of watch cache initializations broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

apiserver\_watch\_cache\_read\_wait\_seconds

Histogram of time spent waiting for a watch cache to become fresh.

- Stability Level:ALPHA
- Type: Histogram
- Labels:resource

apiserver\_watch\_events\_sizes

Watch event size distribution in bytes

- Stability Level:ALPHA
- Type: Histogram
- Labels:groupkindversion

apiserver\_watch\_events\_total

Number of events sent in watch clients

- Stability Level:ALPHA
- Type: Counter
- Labels:groupkindversion

apiserver\_watch\_list\_duration\_seconds

Response latency distribution in seconds for watch list requests broken by group, version, resource and scope.

- Stability Level:ALPHA
- Type: Histogram
- Labels:groupresourcescopeversion

apiserver\_webhooks\_x509\_insecure\_sha1\_total

Counts the number of requests to servers with insecure SHA1 signatures in their serving certificate OR the number of connection failures due to the insecure SHA1 signatures (either/or, based on the runtime environment)

- Stability Level:ALPHA
- Type: Counter

apiserver\_webhooks\_x509\_missing\_san\_total

Counts the number of requests to servers missing SAN extension in their serving certificate OR the number of connection failures due to the lack of x509 certificate SAN extension missing (either/or, based on the runtime environment)

- Stability Level:ALPHA
- Type: Counter

attach\_detach\_controller\_attachdetach\_controller\_forced\_detaches

Number of times the A/D Controller performed a forced detach

- Stability Level:ALPHA
- Type: Counter
- Labels:reason

attachdetach\_controller\_total\_volumes

Number of volumes in A/D Controller

- Stability Level:ALPHA
- Type: Custom
- Labels:plugin\_namestate

authenticated\_user\_requests

Counter of authenticated requests broken out by username.

- Stability Level:ALPHA
- Type: Counter
- Labels:username

authentication\_attempts

Counter of authenticated attempts.

- Stability Level:ALPHA
- Type: Counter
- Labels:result

authentication\_duration\_seconds

Authentication duration in seconds broken out by result.

- Stability Level:ALPHA
- Type: Histogram
- Labels:result

authentication\_token\_cache\_active\_fetch\_count

- Stability Level:ALPHA
- Type: Gauge
- Labels:status

authentication\_token\_cache\_fetch\_total

- Stability Level:ALPHA
- Type: Counter
- Labels:status

authentication\_token\_cache\_request\_duration\_seconds

- Stability Level:ALPHA
- Type: Histogram
- Labels:status

authentication\_token\_cache\_request\_total

- Stability Level:ALPHA
- Type: Counter
- Labels:status

authorization\_attempts\_total

Counter of authorization attempts broken down by result. It can be either 'allowed', 'denied', 'no-opinion' or 'error'.

- Stability Level:ALPHA
- Type: Counter
- Labels:result

authorization\_duration\_seconds

Authorization duration in seconds broken out by result.

- Stability Level:ALPHA
- Type: Histogram
- Labels:result

cloud\_provider\_webhook\_request\_duration\_seconds

Request latency in seconds. Broken down by status code.

- Stability Level:ALPHA
- Type: Histogram
- Labels:codewebhook

cloud\_provider\_webhook\_request\_total

Number of HTTP requests partitioned by status code.

- Stability Level:ALPHA
- Type: Counter
- Labels:codewebhook

cloudprovider\_gce\_api\_request\_duration\_seconds

Latency of a GCE API call

- Stability Level:ALPHA
- Type: Histogram
- Labels:regionrequestversionzone

cloudprovider\_gce\_api\_request\_errors

Number of errors for an API call

- Stability Level:ALPHA
- Type: Counter
- Labels:regionrequestversionzone

container\_swap\_usage\_bytes

Current amount of the container swap usage in bytes. Reported only on non-windows systems

- Stability Level:ALPHA
- Type: Custom
- Labels:containerpodnamespace

csi\_operations\_seconds

Container Storage Interface operation duration with gRPC error code status total

- Stability Level:ALPHA
- Type: Histogram
- Labels:driver\_namegrpc\_status\_codemethod\_namemigrated

endpoint\_slice\_controller\_changes

Number of EndpointSlice changes

- Stability Level:ALPHA
- Type: Counter
- Labels:operation

endpoint\_slice\_controller\_desired\_endpoint\_slices

Number of EndpointSlices that would exist with perfect endpoint allocation

- Stability Level:ALPHA
- Type: Gauge

endpoint\_slice\_controller\_endpoints\_added\_per\_sync

Number of endpoints added on each Service sync

- Stability Level:ALPHA
- Type: Histogram

endpoint\_slice\_controller\_endpoints\_desired

Number of endpoints desired

- Stability Level:ALPHA
- Type: Gauge

endpoint\_slice\_controller\_endpoints\_removed\_per\_sync

Number of endpoints removed on each Service sync

- Stability Level:ALPHA
- Type: Histogram

endpoint\_slice\_controller\_endpointslices\_changed\_per\_sync

Number of EndpointSlices changed on each Service sync

- Stability Level:ALPHA

- Type: Histogram
- Labels: topologytraffic\_distribution

endpoint\_slice\_controller\_num\_endpoint\_slices  
Number of EndpointSlices

- Stability Level: ALPHA
- Type: Gauge

endpoint\_slice\_controller\_services\_count\_by\_traffic\_distribution  
Number of Services using some specific trafficDistribution

- Stability Level: ALPHA
- Type: Gauge
- Labels: traffic\_distribution

endpoint\_slice\_controller\_syncs  
Number of EndpointSlice syncs

- Stability Level: ALPHA
- Type: Counter
- Labels: result

endpoint\_slice\_mirroring\_controller\_addresses\_skipped\_per\_sync  
Number of addresses skipped on each Endpoints sync due to being invalid or exceeding MaxEndpointsPerSubset

- Stability Level: ALPHA
- Type: Histogram

endpoint\_slice\_mirroring\_controller\_changes  
Number of EndpointSlice changes

- Stability Level: ALPHA
- Type: Counter
- Labels: operation

endpoint\_slice\_mirroring\_controller\_desired\_endpoint\_slices  
Number of EndpointSlices that would exist with perfect endpoint allocation

- Stability Level: ALPHA
- Type: Gauge

endpoint\_slice\_mirroring\_controller\_endpoints\_added\_per\_sync  
Number of endpoints added on each Endpoints sync

- Stability Level: ALPHA
- Type: Histogram

endpoint\_slice\_mirroring\_controller\_endpoints\_desired  
Number of endpoints desired

- Stability Level: ALPHA
- Type: Gauge

endpoint\_slice\_mirroring\_controller\_endpoints\_removed\_per\_sync  
Number of endpoints removed on each Endpoints sync

- Stability Level:ALPHA
- Type: Histogram

endpoint\_slice\_mirroring\_controller\_endpoints\_sync\_duration  
Duration of syncEndpoints() in seconds

- Stability Level:ALPHA
- Type: Histogram

endpoint\_slice\_mirroring\_controller\_endpoints\_updated\_per\_sync  
Number of endpoints updated on each Endpoints sync

- Stability Level:ALPHA
- Type: Histogram

endpoint\_slice\_mirroring\_controller\_num\_endpoint\_slices  
Number of EndpointSlices

- Stability Level:ALPHA
- Type: Gauge

ephemeral\_volume\_controller\_create\_failures\_total  
Number of PersistenVolumeClaims creation requests

- Stability Level:ALPHA
- Type: Counter

ephemeral\_volume\_controller\_create\_total  
Number of PersistenVolumeClaims creation requests

- Stability Level:ALPHA
- Type: Counter

etcd\_bookmark\_counts  
Number of etcd bookmarks (progress notify events) split by kind.

- Stability Level:ALPHA
- Type: Gauge
- Labels:resource

etcd\_lease\_object\_counts  
Number of objects attached to a single etcd lease.

- Stability Level:ALPHA
- Type: Histogram

etcd\_request\_duration\_seconds  
Etd request latency in seconds for each operation and object type.

- Stability Level:ALPHA
- Type: Histogram
- Labels:operationtype

etcd\_request\_errors\_total

Etcd failed request counts for each operation and object type.

- Stability Level:ALPHA
- Type: Counter
- Labels:operationtype

etcd\_requests\_total

Etcd request counts for each operation and object type.

- Stability Level:ALPHA
- Type: Counter
- Labels:operationtype

etcd\_version\_info

Etcd server's binary version

- Stability Level:ALPHA
- Type: Gauge
- Labels:binary\_version

field\_validation\_request\_duration\_seconds

Response latency distribution in seconds for each field validation value

- Stability Level:ALPHA
- Type: Histogram
- Labels:field\_validation

force\_cleaned\_failed\_volume\_operation\_errors\_total

The number of volumes that failed force cleanup after their reconstruction failed during kubelet startup.

- Stability Level:ALPHA
- Type: Counter

force\_cleaned\_failed\_volume\_operations\_total

The number of volumes that were force cleaned after their reconstruction failed during kubelet startup. This includes both successful and failed cleanups.

- Stability Level:ALPHA
- Type: Counter

garbagecollector\_controller\_resources\_sync\_error\_total

Number of garbage collector resources sync errors

- Stability Level:ALPHA
- Type: Counter

get\_token\_count

Counter of total Token() requests to the alternate token source

- Stability Level:ALPHA
- Type: Counter

get\_token\_fail\_count

Counter of failed Token() requests to the alternate token source

- Stability Level:ALPHA
- Type: Counter

horizontal\_pod\_autoscaler\_controller\_metric\_computation\_duration\_seconds

The time(seconds) that the HPA controller takes to calculate one metric. The label 'action' should be either 'scale\_down', 'scale\_up', or 'none'. The label 'error' should be either 'spec', 'internal', or 'none'. The label 'metric\_type' corresponds to HPA.spec.metrics[\*].type

- Stability Level:ALPHA
- Type: Histogram
- Labels:actionerrormetric\_type

horizontal\_pod\_autoscaler\_controller\_metric\_computation\_total

Number of metric computations. The label 'action' should be either 'scale\_down', 'scale\_up', or 'none'. Also, the label 'error' should be either 'spec', 'internal', or 'none'. The label 'metric\_type' corresponds to HPA.spec.metrics[\*].type

- Stability Level:ALPHA
- Type: Counter
- Labels:actionerrormetric\_type

horizontal\_pod\_autoscaler\_controller\_reconciliation\_duration\_seconds

The time(seconds) that the HPA controller takes to reconcile once. The label 'action' should be either 'scale\_down', 'scale\_up', or 'none'. Also, the label 'error' should be either 'spec', 'internal', or 'none'. Note that if both spec and internal errors happen during a reconciliation, the first one to occur is reported in `error` label.

- Stability Level:ALPHA
- Type: Histogram
- Labels:actionerror

horizontal\_pod\_autoscaler\_controller\_reconciliations\_total

Number of reconciliations of HPA controller. The label 'action' should be either 'scale\_down', 'scale\_up', or 'none'. Also, the label 'error' should be either 'spec', 'internal', or 'none'. Note that if both spec and internal errors happen during a reconciliation, the first one to occur is reported in `error` label.

- Stability Level:ALPHA
- Type: Counter
- Labels:actionerror

job\_controller\_job\_finished\_indexes\_total

`The number of finished indexes. Possible values for the, status label are: "succeeded", "failed". Possible values for the, backoffLimit label are: "perIndex" and "global"`

- Stability Level:ALPHA
- Type: Counter
- Labels:backoffLimitstatus

job\_controller\_job\_pods\_creation\_total

`The number of Pods created by the Job controller labelled with a reason for the Pod creation., This metric also distinguishes between Pods created using different PodReplacementPolicy

settings., Possible values of the "reason" label are:, "new", "recreate\_terminating\_or\_failed", "recreate\_failed"., Possible values of the "status" label are:, "succeeded", "failed".`

- Stability Level:ALPHA
- Type: Counter
- Labels:reasonstatus

job\_controller\_jobs\_by\_external\_controller\_total  
The number of Jobs managed by an external controller

- Stability Level:ALPHA
- Type: Counter
- Labels:controller\_name

job\_controller\_pod\_failures\_handled\_by\_failure\_policy\_total  
`The number of failed Pods handled by failure policy with, respect to the failure policy action applied based on the matched, rule. Possible values of the action label correspond to the, possible values for the failure policy rule action, which are:, "FailJob", "Ignore" and "Count".`

- Stability Level:ALPHA
- Type: Counter
- Labels:action

job\_controller\_terminated\_pods\_tracking\_finalizer\_total  
`The number of terminated pods (phase=Failed|Succeeded), that have the finalizer batch.kubernetes.io/job-tracking, The event label can be "add" or "delete".`

- Stability Level:ALPHA
- Type: Counter
- Labels:event

kube\_apiserver\_clusterip\_allocator\_allocated\_ips  
Gauge measuring the number of allocated IPs for Services

- Stability Level:ALPHA
- Type: Gauge
- Labels:cidr

kube\_apiserver\_clusterip\_allocator\_allocation\_errors\_total  
Number of errors trying to allocate Cluster IPs

- Stability Level:ALPHA
- Type: Counter
- Labels:cidrscope

kube\_apiserver\_clusterip\_allocator\_allocation\_total  
Number of Cluster IPs allocations

- Stability Level:ALPHA
- Type: Counter
- Labels:cidrscope

kube\_apiserver\_clusterip\_allocator\_available\_ips

Gauge measuring the number of available IPs for Services

- Stability Level:ALPHA
- Type: Gauge
- Labels:cidr

kube\_apiserver\_nodeport\_allocator\_allocated\_ports

Gauge measuring the number of allocated NodePorts for Services

- Stability Level:ALPHA
- Type: Gauge

kube\_apiserver\_nodeport\_allocator\_available\_ports

Gauge measuring the number of available NodePorts for Services

- Stability Level:ALPHA
- Type: Gauge

kube\_apiserver\_pod\_logs\_backend\_tls\_failure\_total

Total number of requests for pods/logs that failed due to kubelet server TLS verification

- Stability Level:ALPHA
- Type: Counter

kube\_apiserver\_pod\_logs\_insecure\_backend\_total

Total number of requests for pods/logs sliced by usage type: enforce\_tls, skip\_tls\_allowed, skip\_tls\_denied

- Stability Level:ALPHA
- Type: Counter
- Labels:usage

kube\_apiserver\_pod\_logs\_pods\_logs\_backend\_tls\_failure\_total

Total number of requests for pods/logs that failed due to kubelet server TLS verification

- Stability Level:ALPHA
- Type: Counter
- Deprecated Versions:1.27.0

kube\_apiserver\_pod\_logs\_pods\_logs\_insecure\_backend\_total

Total number of requests for pods/logs sliced by usage type: enforce\_tls, skip\_tls\_allowed, skip\_tls\_denied

- Stability Level:ALPHA
- Type: Counter
- Labels:usage
- Deprecated Versions:1.27.0

kubelet\_active\_pods

The number of pods the kubelet considers active and which are being considered when admitting new pods. static is true if the pod is not from the apiserver.

- Stability Level:ALPHA
- Type: Gauge
- Labels:static

kubelet\_certificate\_manager\_client\_expiration\_renew\_errors

Counter of certificate renewal errors.

- Stability Level:ALPHA
- Type: Counter

kubelet\_certificate\_manager\_client\_ttl\_seconds

Gauge of the TTL (time-to-live) of the Kubelet's client certificate. The value is in seconds until certificate expiry (negative if already expired). If client certificate is invalid or unused, the value will be +INF.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_certificate\_manager\_server\_rotation\_seconds

Histogram of the number of seconds the previous certificate lived before being rotated.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_certificate\_manager\_server\_ttl\_seconds

Gauge of the shortest TTL (time-to-live) of the Kubelet's serving certificate. The value is in seconds until certificate expiry (negative if already expired). If serving certificate is invalid or unused, the value will be +INF.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_cgroup\_manager\_duration\_seconds

Duration in seconds for cgroup manager operations. Broken down by method.

- Stability Level:ALPHA
- Type: Histogram
- Labels:operation\_type

kubelet\_container\_log\_filesystem\_used\_bytes

Bytes used by the container's logs on the filesystem.

- Stability Level:ALPHA
- Type: Custom
- Labels:uidnamespacepodcontainer

kubelet\_containers\_per\_pod\_count

The number of containers per pod.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_cpu\_manager\_pinning\_errors\_total

The number of cpu core allocations which required pinning failed.

- Stability Level:ALPHA
- Type: Counter

kubelet\_cpu\_manager\_pinning\_requests\_total

The number of cpu core allocations which required pinning.

- Stability Level:ALPHA
- Type: Counter

kubelet\_credential\_provider\_plugin\_duration

Duration of execution in seconds for credential provider plugin

- Stability Level:ALPHA
- Type: Histogram
- Labels:plugin\_name

kubelet\_credential\_provider\_plugin\_errors

Number of errors from credential provider plugin

- Stability Level:ALPHA
- Type: Counter
- Labels:plugin\_name

kubelet\_desired\_pods

The number of pods the kubelet is being instructed to run. static is true if the pod is not from the apiserver.

- Stability Level:ALPHA
- Type: Gauge
- Labels:static

kubelet\_device\_plugin\_alloc\_duration\_seconds

Duration in seconds to serve a device plugin Allocation request. Broken down by resource name.

- Stability Level:ALPHA
- Type: Histogram
- Labels:resource\_name

kubelet\_device\_plugin\_registration\_total

Cumulative number of device plugin registrations. Broken down by resource name.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource\_name

kubelet\_evented\_pleg\_connection\_error\_count

The number of errors encountered during the establishment of streaming connection with the CRI runtime.

- Stability Level:ALPHA
- Type: Counter

kubelet\_evented\_pleg\_connection\_latency\_seconds

The latency of streaming connection with the CRI runtime, measured in seconds.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_evented\_pleg\_connection\_success\_count

The number of times a streaming client was obtained to receive CRI Events.

- Stability Level:ALPHA
- Type: Counter

kubelet\_eviction\_stats\_age\_seconds

Time between when stats are collected, and when pod is evicted based on those stats by eviction signal

- Stability Level:ALPHA
- Type: Histogram
- Labels:eviction\_signal

kubelet\_evictions

Cumulative number of pod evictions by eviction signal

- Stability Level:ALPHA
- Type: Counter
- Labels:eviction\_signal

kubelet\_graceful\_shutdown\_end\_time\_seconds

Last graceful shutdown start time since unix epoch in seconds

- Stability Level:ALPHA
- Type: Gauge

kubelet\_graceful\_shutdown\_start\_time\_seconds

Last graceful shutdown start time since unix epoch in seconds

- Stability Level:ALPHA
- Type: Gauge

kubelet\_http\_inflight\_requests

Number of the inflight http requests

- Stability Level:ALPHA
- Type: Gauge
- Labels:long\_runningmethodpathserver\_type

kubelet\_http\_requests\_duration\_seconds

Duration in seconds to serve http requests

- Stability Level:ALPHA
- Type: Histogram
- Labels:long\_runningmethodpathserver\_type

kubelet\_http\_requests\_total

Number of the http requests received since the server started

- Stability Level:ALPHA
- Type: Counter
- Labels:long\_runningmethodpathserver\_type

kubelet\_image\_garbage\_collected\_total

Total number of images garbage collected by the kubelet, whether through disk usage or image age.

- Stability Level:ALPHA
- Type: Counter
- Labels:reason

kubelet\_image\_pull\_duration\_seconds

Duration in seconds to pull an image.

- Stability Level:ALPHA
- Type: Histogram
- Labels:image\_size\_in\_bytes

kubelet\_lifecycle\_handler\_http\_fallbacks\_total

The number of times lifecycle handlers successfully fell back to http from https.

- Stability Level:ALPHA
- Type: Counter

kubelet\_managed\_ephemeral\_containers

Current number of ephemeral containers in pods managed by this kubelet.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_memory\_manager\_pinning\_errors\_total

The number of memory pages allocations which required pinning that failed.

- Stability Level:ALPHA
- Type: Counter

kubelet\_memory\_manager\_pinning\_requests\_total

The number of memory pages allocations which required pinning.

- Stability Level:ALPHA
- Type: Counter

kubelet\_mirror\_pods

The number of mirror pods the kubelet will try to create (one per admitted static pod)

- Stability Level:ALPHA
- Type: Gauge

kubelet\_node\_name

The node's name. The count is always 1.

- Stability Level:ALPHA
- Type: Gauge
- Labels:node

kubelet\_node\_startup\_duration\_seconds

Duration in seconds of node startup in total.

- Stability Level:ALPHA

- Type: Gauge

kubelet\_node\_startup\_post\_registration\_duration\_seconds  
Duration in seconds of node startup after registration.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_node\_startup\_pre\_kubelet\_duration\_seconds  
Duration in seconds of node startup before kubelet starts.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_node\_startup\_pre\_registration\_duration\_seconds  
Duration in seconds of node startup before registration.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_node\_startup\_registration\_duration\_seconds  
Duration in seconds of node startup during registration.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_orphan\_pod\_cleaned\_volumes  
The total number of orphaned Pods whose volumes were cleaned in the last periodic sweep.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_orphan\_pod\_cleaned\_volumes\_errors  
The number of orphaned Pods whose volumes failed to be cleaned in the last periodic sweep.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_orphaned\_runtime\_pods\_total  
Number of pods that have been detected in the container runtime without being already known to the pod worker. This typically indicates the kubelet was restarted while a pod was force deleted in the API or in the local configuration, which is unusual.

- Stability Level:ALPHA
- Type: Counter

kubelet\_pleg\_discard\_events  
The number of discard events in PLEG.

- Stability Level:ALPHA
- Type: Counter

kubelet\_pleg\_last\_seen\_seconds

Timestamp in seconds when PLEG was last seen active.

- Stability Level:ALPHA
- Type: Gauge

kubelet\_pleg\_relist\_duration\_seconds

Duration in seconds for relisting pods in PLEG.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pleg\_relist\_interval\_seconds

Interval in seconds between relisting in PLEG.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pod\_resources\_endpoint\_errors\_get

Number of requests to the PodResource Get endpoint which returned error. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_errors\_get\_allocatable

Number of requests to the PodResource GetAllocatableResources endpoint which returned error. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_errors\_list

Number of requests to the PodResource List endpoint which returned error. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_requests\_get

Number of requests to the PodResource Get endpoint. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_requests\_get\_allocatable

Number of requests to the PodResource GetAllocatableResources endpoint. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_requests\_list

Number of requests to the PodResource List endpoint. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_resources\_endpoint\_requests\_total

Cumulative number of requests to the PodResource endpoint. Broken down by server api version.

- Stability Level:ALPHA
- Type: Counter
- Labels:server\_api\_version

kubelet\_pod\_start\_duration\_seconds

Duration in seconds from kubelet seeing a pod for the first time to the pod starting to run

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pod\_start\_sli\_duration\_seconds

Duration in seconds to start a pod, excluding time to pull images and run init containers, measured from pod creation timestamp to when all its containers are reported as started and observed via watch

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pod\_start\_total\_duration\_seconds

Duration in seconds to start a pod since creation, including time to pull images and run init containers, measured from pod creation timestamp to when all its containers are reported as started and observed via watch

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pod\_status\_sync\_duration\_seconds

Duration in seconds to sync a pod status update. Measures time from detection of a change to pod status until the API is successfully updated for that pod, even if multiple intervening changes to pod status occur.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_pod\_worker\_duration\_seconds

Duration in seconds to sync a single pod. Broken down by operation type: create, update, or sync

- Stability Level:ALPHA
- Type: Histogram
- Labels:operation\_type

kubelet\_pod\_worker\_start\_duration\_seconds

Duration in seconds from kubelet seeing a pod to starting a worker.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_preemptions

Cumulative number of pod preemptions by preemption resource

- Stability Level:ALPHA
- Type: Counter
- Labels:preemption\_signal

kubelet\_restarted\_pods\_total

Number of pods that have been restarted because they were deleted and recreated with the same UID while the kubelet was watching them (common for static pods, extremely uncommon for API pods)

- Stability Level:ALPHA
- Type: Counter
- Labels:static

kubelet\_run\_podsandbox\_duration\_seconds

Duration in seconds of the run\_podsandbox operations. Broken down by RuntimeClass.Handler.

- Stability Level:ALPHA
- Type: Histogram
- Labels:runtime\_handler

kubelet\_run\_podsandbox\_errors\_total

Cumulative number of the run\_podsandbox operation errors by RuntimeClass.Handler.

- Stability Level:ALPHA
- Type: Counter
- Labels:runtime\_handler

kubelet\_running\_containers

Number of containers currently running

- Stability Level:ALPHA
- Type: Gauge
- Labels:container\_state

kubelet\_running\_pods

Number of pods that have a running pod sandbox

- Stability Level:ALPHA
- Type: Gauge

kubelet\_runtime\_operations\_duration\_seconds

Duration in seconds of runtime operations. Broken down by operation type.

- Stability Level:ALPHA
- Type: Histogram
- Labels:operation\_type

kubelet\_runtime\_operations\_errors\_total

Cumulative number of runtime operation errors by operation type.

- Stability Level:ALPHA
- Type: Counter
- Labels:operation\_type

kubelet\_runtime\_operations\_total

Cumulative number of runtime operations by operation type.

- Stability Level:ALPHA
- Type: Counter
- Labels:operation\_type

kubelet\_server\_expiration\_renew\_errors

Counter of certificate renewal errors.

- Stability Level:ALPHA
- Type: Counter

kubelet\_sleep\_action\_terminated\_early\_total

The number of times lifecycle sleep handler got terminated before it finishes

- Stability Level:ALPHA
- Type: Counter

kubelet\_started\_containers\_errors\_total

Cumulative number of errors when starting containers

- Stability Level:ALPHA
- Type: Counter
- Labels:codecontainer\_type

kubelet\_started\_containers\_total

Cumulative number of containers started

- Stability Level:ALPHA
- Type: Counter
- Labels:container\_type

kubelet\_started\_host\_process\_containers\_errors\_total

Cumulative number of errors when starting hostprocess containers. This metric will only be collected on Windows.

- Stability Level:ALPHA
- Type: Counter
- Labels:codecontainer\_type

kubelet\_started\_host\_process\_containers\_total

Cumulative number of hostprocess containers started. This metric will only be collected on Windows.

- Stability Level:ALPHA
- Type: Counter
- Labels:container\_type

kubelet\_started\_pods\_errors\_total  
Cumulative number of errors when starting pods

- Stability Level:ALPHA
- Type: Counter

kubelet\_started\_pods\_total  
Cumulative number of pods started

- Stability Level:ALPHA
- Type: Counter

kubelet\_topology\_manager\_admission\_duration\_ms  
Duration in milliseconds to serve a pod admission request.

- Stability Level:ALPHA
- Type: Histogram

kubelet\_topology\_manager\_admission\_errors\_total  
The number of admission request failures where resources could not be aligned.

- Stability Level:ALPHA
- Type: Counter

kubelet\_topology\_manager\_admission\_requests\_total  
The number of admission requests where resources have to be aligned.

- Stability Level:ALPHA
- Type: Counter

kubelet\_volume\_metric\_collection\_duration\_seconds  
Duration in seconds to calculate volume stats

- Stability Level:ALPHA
- Type: Histogram
- Labels:metric\_source

kubelet\_volume\_stats\_available\_bytes  
Number of available bytes in the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_capacity\_bytes  
Capacity in bytes of the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_health\_status\_abnormal

Abnormal volume health status. The count is either 1 or 0. 1 indicates the volume is unhealthy, 0 indicates volume is healthy

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_inodes

Maximum number of inodes in the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_inodes\_free

Number of free inodes in the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_inodes\_used

Number of used inodes in the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_volume\_stats\_used\_bytes

Number of used bytes in the volume

- Stability Level:ALPHA
- Type: Custom
- Labels:namespacepersistentvolumeclaim

kubelet\_working\_pods

Number of pods the kubelet is actually running, broken down by lifecycle phase, whether the pod is desired, orphaned, or runtime only (also orphaned), and whether the pod is static. An orphaned pod has been removed from local configuration or force deleted in the API and consumes resources that are not otherwise visible.

- Stability Level:ALPHA
- Type: Gauge
- Labels:configlifecyclestatic

kubeproxy\_network\_programming\_duration\_seconds

In Cluster Network Programming Latency in seconds

- Stability Level:ALPHA
- Type: Histogram

kubeproxy\_proxy\_healthz\_total

Cumulative proxy healthz HTTP status

- Stability Level:ALPHA

- Type: Counter
- Labels:code

kubeproxy\_proxy\_livez\_total  
Cumulative proxy livez HTTP status

- Stability Level:ALPHA
- Type: Counter
- Labels:code

kubeproxy\_sync\_full\_proxy\_rules\_duration\_seconds  
SyncProxyRules latency in seconds for full resyncs

- Stability Level:ALPHA
- Type: Histogram

kubeproxy\_sync\_partial\_proxy\_rules\_duration\_seconds  
SyncProxyRules latency in seconds for partial resyncs

- Stability Level:ALPHA
- Type: Histogram

kubeproxy\_sync\_proxy\_rules\_duration\_seconds  
SyncProxyRules latency in seconds

- Stability Level:ALPHA
- Type: Histogram

kubeproxy\_sync\_proxy\_rules\_endpoint\_changes\_pending  
Pending proxy rules Endpoint changes

- Stability Level:ALPHA
- Type: Gauge

kubeproxy\_sync\_proxy\_rules\_endpoint\_changes\_total  
Cumulative proxy rules Endpoint changes

- Stability Level:ALPHA
- Type: Counter

kubeproxy\_sync\_proxy\_rules\_iptables\_last  
Number of iptables rules written by kube-proxy in last sync

- Stability Level:ALPHA
- Type: Gauge
- Labels:table

kubeproxy\_sync\_proxy\_rules\_iptables\_partial\_restore\_failures\_total  
Cumulative proxy iptables partial restore failures

- Stability Level:ALPHA
- Type: Counter

kubeproxy\_sync\_proxy\_rules\_iptables\_restore\_failures\_total

## Cumulative proxy iptables restore failures

- Stability Level:ALPHA
- Type: Counter

## kubeproxy\_sync\_proxy\_rules\_iptables\_total

Total number of iptables rules owned by kube-proxy

- Stability Level:ALPHA
- Type: Gauge
- Labels:table

## kubeproxy\_sync\_proxy\_rules\_last\_queued\_timestamp\_seconds

The last time a sync of proxy rules was queued

- Stability Level:ALPHA
- Type: Gauge

## kubeproxy\_sync\_proxy\_rules\_last\_timestamp\_seconds

The last time proxy rules were successfully synced

- Stability Level:ALPHA
- Type: Gauge

## kubeproxy\_sync\_proxy\_rules\_no\_local\_endpoints\_total

Number of services with a Local traffic policy and no endpoints

- Stability Level:ALPHA
- Type: Gauge
- Labels:traffic\_policy

## kubeproxy\_sync\_proxy\_rules\_service\_changes\_pending

Pending proxy rules Service changes

- Stability Level:ALPHA
- Type: Gauge

## kubeproxy\_sync\_proxy\_rules\_service\_changes\_total

Cumulative proxy rules Service changes

- Stability Level:ALPHA
- Type: Counter

## kubernetes\_build\_info

A metric with a constant '1' value labeled by major, minor, git version, git commit, git tree state, build date, Go version, and compiler from which Kubernetes was built, and platform on which it is running.

- Stability Level:ALPHA
- Type: Gauge
- Labels:build\_datecompilergit\_commitgit\_tree\_stategit\_versiongo\_versionmajorminormapplatform

## leader\_election\_master\_status

Gauge of if the reporting system is master of the relevant lease, 0 indicates backup, 1 indicates master. 'name' is the string used to identify the lease. Please make sure to group by name.

- Stability Level:ALPHA
- Type: Gauge
- Labels:name

leader\_election\_slowpath\_total

Total number of slow path exercised in renewing leader leases. 'name' is the string used to identify the lease. Please make sure to group by name.

- Stability Level:ALPHA
- Type: Counter
- Labels:name

node\_authorizer\_graph\_actions\_duration\_seconds

Histogram of duration of graph actions in node authorizer.

- Stability Level:ALPHA
- Type: Histogram
- Labels:operation

node\_collector\_unhealthy\_nodes\_in\_zone

Gauge measuring number of not Ready Nodes per zones.

- Stability Level:ALPHA
- Type: Gauge
- Labels:zone

node\_collector\_update\_all\_nodes\_health\_duration\_seconds

Duration in seconds for NodeController to update the health of all nodes.

- Stability Level:ALPHA
- Type: Histogram

node\_collector\_update\_node\_health\_duration\_seconds

Duration in seconds for NodeController to update the health of a single node.

- Stability Level:ALPHA
- Type: Histogram

node\_collector\_zone\_health

Gauge measuring percentage of healthy nodes per zone.

- Stability Level:ALPHA
- Type: Gauge
- Labels:zone

node\_collector\_zone\_size

Gauge measuring number of registered Nodes per zones.

- Stability Level:ALPHA
- Type: Gauge
- Labels:zone

node\_controller\_cloud\_provider\_taint\_removal\_delay\_seconds

Number of seconds after node creation when NodeController removed the cloud-provider taint of a single node.

- Stability Level:ALPHA
- Type: Histogram

node\_controller\_initial\_node\_sync\_delay\_seconds

Number of seconds after node creation when NodeController finished the initial synchronization of a single node.

- Stability Level:ALPHA
- Type: Histogram

node\_ipam\_controller\_cidrset\_allocation\_tries\_per\_request

Number of endpoints added on each Service sync

- Stability Level:ALPHA
- Type: Histogram
- Labels:clusterCIDR

node\_ipam\_controller\_cidrset\_cidrs\_allocations\_total

Counter measuring total number of CIDR allocations.

- Stability Level:ALPHA
- Type: Counter
- Labels:clusterCIDR

node\_ipam\_controller\_cidrset\_cidrs\_releases\_total

Counter measuring total number of CIDR releases.

- Stability Level:ALPHA
- Type: Counter
- Labels:clusterCIDR

node\_ipam\_controller\_cidrset\_usage\_cidrs

Gauge measuring percentage of allocated CIDRs.

- Stability Level:ALPHA
- Type: Gauge
- Labels:clusterCIDR

node\_ipam\_controller\_cirdset\_max\_cidrs

Maximum number of CIDRs that can be allocated.

- Stability Level:ALPHA
- Type: Gauge
- Labels:clusterCIDR

node\_swap\_usage\_bytes

Current swap usage of the node in bytes. Reported only on non-windows systems

- Stability Level:ALPHA
- Type: Custom

number\_of\_l4\_ilbs

Number of L4 ILBs

- Stability Level:ALPHA
- Type: Gauge
- Labels:feature

plugin\_manager\_total\_plugins

Number of plugins in Plugin Manager

- Stability Level:ALPHA
- Type: Custom
- Labels:socket\_pathstate

pod\_gc\_collector\_force\_delete\_pod\_errors\_total

Number of errors encountered when forcefully deleting the pods since the Pod GC Controller started.

- Stability Level:ALPHA
- Type: Counter
- Labels:namespace

pod\_gc\_collector\_force\_delete\_pods\_total

Number of pods that are being forcefully deleted since the Pod GC Controller started.

- Stability Level:ALPHA
- Type: Counter
- Labels:namespace

pod\_security\_errors\_total

Number of errors preventing normal evaluation. Non-fatal errors may result in the latest restricted profile being used for evaluation.

- Stability Level:ALPHA
- Type: Counter
- Labels:fatalrequest\_operationresourcesubresource

pod\_security\_evaluations\_total

Number of policy evaluations that occurred, not counting ignored or exempt requests.

- Stability Level:ALPHA
- Type: Counter
- Labels:decisionmodepolicy\_levelpolicy\_versionrequest\_operationresourcesubresource

pod\_security\_exemptions\_total

Number of exempt requests, not counting ignored or out of scope requests.

- Stability Level:ALPHA
- Type: Counter
- Labels:request\_operationresourcesubresource

pod\_swap\_usage\_bytes

Current amount of the pod swap usage in bytes. Reported only on non-windows systems

- Stability Level:ALPHA

- Type: Custom
- Labels: podnamespace

prober\_probe\_duration\_seconds

Duration in seconds for a probe response.

- Stability Level: ALPHA
- Type: Histogram
- Labels: containernamespacepodprobe\_type

prober\_probe\_total

Cumulative number of a liveness, readiness or startup probe for a container by result.

- Stability Level: ALPHA
- Type: Counter
- Labels: containernamespacepodpod\_uidprobe\_typeresult

pv\_collector\_bound\_pv\_count

Gauge measuring number of persistent volume currently bound

- Stability Level: ALPHA
- Type: Custom
- Labels: storage\_class

pv\_collector\_bound\_pvc\_count

Gauge measuring number of persistent volume claim currently bound

- Stability Level: ALPHA
- Type: Custom
- Labels: namespace

pv\_collector\_total\_pv\_count

Gauge measuring total number of persistent volumes

- Stability Level: ALPHA
- Type: Custom
- Labels: plugin\_namevolume\_mode

pv\_collector\_unbound\_pv\_count

Gauge measuring number of persistent volume currently unbound

- Stability Level: ALPHA
- Type: Custom
- Labels: storage\_class

pv\_collector\_unbound\_pvc\_count

Gauge measuring number of persistent volume claim currently unbound

- Stability Level: ALPHA
- Type: Custom
- Labels: namespace

reconstruct\_volume\_operations\_errors\_total

The number of volumes that failed reconstruction from the operating system during kubelet startup.

- Stability Level:ALPHA
- Type: Counter

reconstruct\_volume\_operations\_total

The number of volumes that were attempted to be reconstructed from the operating system during kubelet startup. This includes both successful and failed reconstruction.

- Stability Level:ALPHA
- Type: Counter

replicaset\_controller\_sorting\_deletion\_age\_ratio

The ratio of chosen deleted pod's ages to the current youngest pod's age (at the time). Should be <2. The intent of this metric is to measure the rough efficacy of the LogarithmicScaleDown feature gate's effect on the sorting (and deletion) of pods when a replicaset scales down. This only considers Ready pods when calculating and reporting.

- Stability Level:ALPHA
- Type: Histogram

resourceclaim\_controller\_create\_attempts\_total

Number of ResourceClaims creation requests

- Stability Level:ALPHA
- Type: Counter

resourceclaim\_controller\_create\_failures\_total

Number of ResourceClaims creation request failures

- Stability Level:ALPHA
- Type: Counter

rest\_client\_dns\_resolution\_duration\_seconds

DNS resolver latency in seconds. Broken down by host.

- Stability Level:ALPHA
- Type: Histogram
- Labels:host

rest\_client\_exec\_plugin\_call\_total

Number of calls to an exec plugin, partitioned by the type of event encountered (no\_error, plugin\_execution\_error, plugin\_not\_found\_error, client\_internal\_error) and an optional exit code. The exit code will be set to 0 if and only if the plugin call was successful.

- Stability Level:ALPHA
- Type: Counter
- Labels:call\_statuscode

rest\_client\_exec\_plugin\_certificate\_rotation\_age

Histogram of the number of seconds the last auth exec plugin client certificate lived before being rotated. If auth exec plugin client certificates are unused, histogram will contain no data.

- Stability Level:ALPHA

- Type: Histogram

rest\_client\_exec\_plugin\_ttl\_seconds

Gauge of the shortest TTL (time-to-live) of the client certificate(s) managed by the auth exec plugin. The value is in seconds until certificate expiry (negative if already expired). If auth exec plugins are unused or manage no TLS certificates, the value will be +INF.

- Stability Level:ALPHA
- Type: Gauge

rest\_client\_rate\_limiter\_duration\_seconds

Client side rate limiter latency in seconds. Broken down by verb, and host.

- Stability Level:ALPHA
- Type: Histogram
- Labels:hostverb

rest\_client\_request\_duration\_seconds

Request latency in seconds. Broken down by verb, and host.

- Stability Level:ALPHA
- Type: Histogram
- Labels:hostverb

rest\_client\_request\_retries\_total

Number of request retries, partitioned by status code, verb, and host.

- Stability Level:ALPHA
- Type: Counter
- Labels:codehostverb

rest\_client\_request\_size\_bytes

Request size in bytes. Broken down by verb and host.

- Stability Level:ALPHA
- Type: Histogram
- Labels:hostverb

rest\_client\_requests\_total

Number of HTTP requests, partitioned by status code, method, and host.

- Stability Level:ALPHA
- Type: Counter
- Labels:codehostmethod

rest\_client\_response\_size\_bytes

Response size in bytes. Broken down by verb and host.

- Stability Level:ALPHA
- Type: Histogram
- Labels:hostverb

rest\_client\_transport\_cache\_entries

Number of transport entries in the internal cache.

- Stability Level:ALPHA
- Type: Gauge

rest\_client\_transport\_create\_calls\_total

Number of calls to get a new transport, partitioned by the result of the operation hit: obtained from the cache, miss: created and added to the cache, uncacheable: created and not cached

- Stability Level:ALPHA
- Type: Counter
- Labels:result

retroactive\_storageclass\_errors\_total

Total number of failed retroactive StorageClass assignments to persistent volume claim

- Stability Level:ALPHA
- Type: Counter

retroactive\_storageclass\_total

Total number of retroactive StorageClass assignments to persistent volume claim

- Stability Level:ALPHA
- Type: Counter

root\_ca\_cert\_publisher\_sync\_duration\_seconds

Number of namespace syncs happened in root ca cert publisher.

- Stability Level:ALPHA
- Type: Histogram
- Labels:code

root\_ca\_cert\_publisher\_sync\_total

Number of namespace syncs happened in root ca cert publisher.

- Stability Level:ALPHA
- Type: Counter
- Labels:code

running\_managed\_controllers

Indicates where instances of a controller are currently running

- Stability Level:ALPHA
- Type: Gauge
- Labels:managername

scheduler\_goroutines

Number of running goroutines split by the work they do such as binding.

- Stability Level:ALPHA
- Type: Gauge
- Labels:operation

scheduler\_permit\_wait\_duration\_seconds

Duration of waiting on permit.

- Stability Level:ALPHA
- Type: Histogram
- Labels:result

scheduler\_plugin\_evaluation\_total

Number of attempts to schedule pods by each plugin and the extension point (available only in PreFilter, Filter, PreScore, and Score).

- Stability Level:ALPHA
- Type: Counter
- Labels:extension\_pointpluginprofile

scheduler\_plugin\_execution\_duration\_seconds

Duration for running a plugin at a specific extension point.

- Stability Level:ALPHA
- Type: Histogram
- Labels:extension\_pointpluginstatus

scheduler\_scheduler\_cache\_size

Number of nodes, pods, and assumed (bound) pods in the scheduler cache.

- Stability Level:ALPHA
- Type: Gauge
- Labels:type

scheduler\_scheduling\_algorithm\_duration\_seconds

Scheduling algorithm latency in seconds

- Stability Level:ALPHA
- Type: Histogram

scheduler\_unschedulable\_pods

The number of unschedulable pods broken down by plugin name. A pod will increment the gauge for all plugins that caused it to not schedule and so this metric have meaning only when broken down by plugin.

- Stability Level:ALPHA
- Type: Gauge
- Labels:pluginprofile

scheduler\_volume\_binder\_cache\_requests\_total

Total number for request volume binding cache

- Stability Level:ALPHA
- Type: Counter
- Labels:operation

scheduler\_volume\_scheduling\_stage\_error\_total

Volume scheduling stage error count

- Stability Level:ALPHA
- Type: Counter

- Labels:operation

scrape\_error

1 if there was an error while getting container metrics, 0 otherwise

- Stability Level:ALPHA
- Type: Custom
- Deprecated Versions:1.29.0

service\_controller\_loadbalancer\_sync\_total

A metric counting the amount of times any load balancer has been configured, as an effect of service/node changes on the cluster

- Stability Level:ALPHA
- Type: Counter

service\_controller\_nodesync\_error\_total

A metric counting the amount of times any load balancer has been configured and errored, as an effect of node changes on the cluster

- Stability Level:ALPHA
- Type: Counter

service\_controller\_nodesync\_latency\_seconds

A metric measuring the latency for nodesync which updates loadbalancer hosts on cluster node updates.

- Stability Level:ALPHA
- Type: Histogram

service\_controller\_update\_loadbalancer\_host\_latency\_seconds

A metric measuring the latency for updating each load balancer hosts.

- Stability Level:ALPHA
- Type: Histogram

serviceaccount\_invalid\_legacy\_auto\_token\_uses\_total

Cumulative invalid auto-generated legacy tokens used

- Stability Level:ALPHA
- Type: Counter

serviceaccount\_legacy\_auto\_token\_uses\_total

Cumulative auto-generated legacy tokens used

- Stability Level:ALPHA
- Type: Counter

serviceaccount\_legacy\_manual\_token\_uses\_total

Cumulative manually created legacy tokens used

- Stability Level:ALPHA
- Type: Counter

serviceaccount\_legacy\_tokens\_total

Cumulative legacy service account tokens used

- Stability Level:ALPHA
- Type: Counter

serviceaccount\_stale\_tokens\_total

Cumulative stale projected service account tokens used

- Stability Level:ALPHA
- Type: Counter

serviceaccount\_valid\_tokens\_total

Cumulative valid projected service account tokens used

- Stability Level:ALPHA
- Type: Counter

storage\_count\_attachable\_volumes\_in\_use

Measure number of volumes in use

- Stability Level:ALPHA
- Type: Custom
- Labels:nodevolume\_plugin

storage\_operation\_duration\_seconds

Storage operation duration

- Stability Level:ALPHA
- Type: Histogram
- Labels:migratedoperation\_namestatusvolume\_plugin

taint\_eviction\_controller\_pod\_deletion\_duration\_seconds

Latency, in seconds, between the time when a taint effect has been activated for the Pod and its deletion via TaintEvictionController.

- Stability Level:ALPHA
- Type: Histogram

taint\_eviction\_controller\_pod\_deletions\_total

Total number of Pods deleted by TaintEvictionController since its start.

- Stability Level:ALPHA
- Type: Counter

ttl\_after\_finished\_controller\_job\_deletion\_duration\_seconds

The time it took to delete the job since it became eligible for deletion

- Stability Level:ALPHA
- Type: Histogram

volume\_manager\_selinux\_container\_errors\_total

Number of errors when kubelet cannot compute SELinux context for a container. Kubelet can't start such a Pod then and it will retry, therefore value of this metric may not represent the actual nr. of containers.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_mode

volume\_manager\_selinux\_container\_warnings\_total

Number of errors when kubelet cannot compute SELinux context for a container that are ignored. They will become real errors when SELinuxMountReadWriteOncePod feature is expanded to all volume access modes.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_mode

volume\_manager\_selinux\_pod\_context\_mismatch\_errors\_total

Number of errors when a Pod defines different SELinux contexts for its containers that use the same volume. Kubelet can't start such a Pod then and it will retry, therefore value of this metric may not represent the actual nr. of Pods.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_mode

volume\_manager\_selinux\_pod\_context\_mismatch\_warnings\_total

Number of errors when a Pod defines different SELinux contexts for its containers that use the same volume. They are not errors yet, but they will become real errors when SELinuxMountReadWriteOncePod feature is expanded to all volume access modes.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_mode

volume\_manager\_selinux\_volume\_context\_mismatch\_errors\_total

Number of errors when a Pod uses a volume that is already mounted with a different SELinux context than the Pod needs. Kubelet can't start such a Pod then and it will retry, therefore value of this metric may not represent the actual nr. of Pods.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_modevolume\_plugin

volume\_manager\_selinux\_volume\_context\_mismatch\_warnings\_total

Number of errors when a Pod uses a volume that is already mounted with a different SELinux context than the Pod needs. They are not errors yet, but they will become real errors when SELinuxMountReadWriteOncePod feature is expanded to all volume access modes.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_modevolume\_plugin

volume\_manager\_selinux\_volumes\_admitted\_total

Number of volumes whose SELinux context was fine and will be mounted with mount -o context option.

- Stability Level:ALPHA
- Type: Gauge
- Labels:access\_modevolume\_plugin

volume\_manager\_total\_volumes

Number of volumes in Volume Manager

- Stability Level:ALPHA
- Type: Custom
- Labels:plugin\_namestate

volume\_operation\_total\_errors

Total volume operation errors

- Stability Level:ALPHA
- Type: Counter
- Labels:operation\_nameplugin\_name

volume\_operation\_total\_seconds

Storage operation end to end duration in seconds

- Stability Level:ALPHA
- Type: Histogram
- Labels:operation\_nameplugin\_name

watch\_cache\_capacity

Total capacity of watch cache broken by resource type.

- Stability Level:ALPHA
- Type: Gauge
- Labels:resource

watch\_cache\_capacity\_decrease\_total

Total number of watch cache capacity decrease events broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

watch\_cache\_capacity\_increase\_total

Total number of watch cache capacity increase events broken by resource type.

- Stability Level:ALPHA
- Type: Counter
- Labels:resource

workqueue\_adds\_total

Total number of adds handled by workqueue

- Stability Level:ALPHA
- Type: Counter
- Labels:name

workqueue\_depth  
Current depth of workqueue

- Stability Level:ALPHA
- Type: Gauge
- Labels:name

workqueue\_longest\_running\_processor\_seconds  
How many seconds has the longest running processor for workqueue been running.

- Stability Level:ALPHA
- Type: Gauge
- Labels:name

workqueue\_queue\_duration\_seconds  
How long in seconds an item stays in workqueue before being requested.

- Stability Level:ALPHA
- Type: Histogram
- Labels:name

workqueue\_retries\_total  
Total number of retries handled by workqueue

- Stability Level:ALPHA
- Type: Counter
- Labels:name

workqueue\_unfinished\_work\_seconds  
How many seconds of work has done that is in progress and hasn't been observed by work\_duration. Large values indicate stuck threads. One can deduce the number of stuck threads by observing the rate at which this increases.

- Stability Level:ALPHA
- Type: Gauge
- Labels:name

workqueue\_work\_duration\_seconds  
How long in seconds processing an item from workqueue takes.

- Stability Level:ALPHA
- Type: Histogram
- Labels:name

# Kubernetes Issues and Security

---

[Kubernetes Issue Tracker](#)

[Kubernetes Security and Disclosure Information](#)

[Official CVE Feed](#)

# Kubernetes Issue Tracker

To report a security issue, please follow the [Kubernetes security disclosure process](#).

Work on Kubernetes code and public issues are tracked using [GitHub Issues](#).

- Official [list of known CVEs](#) (security vulnerabilities) that have been announced by the [Security Response Committee](#)
- [CVE-related GitHub issues](#)

Security-related announcements are sent to the [kubernetes-security-announce@googlegroups.com](mailto:kubernetes-security-announce@googlegroups.com) mailing list.

## Kubernetes Security and Disclosure Information

This page describes Kubernetes security and disclosure information.

### Security Announcements

Join the [kubernetes-security-announce](#) group for emails about security and major API announcements.

### Report a Vulnerability

We're extremely grateful for security researchers and users that report vulnerabilities to the Kubernetes Open Source Community. All reports are thoroughly investigated by a set of community volunteers.

To make a report, submit your vulnerability to the [Kubernetes bug bounty program](#). This allows triage and handling of the vulnerability with standardized response times.

You can also email the private [security@kubernetes.io](mailto:security@kubernetes.io) list with the security details and the details expected for [all Kubernetes bug reports](#).

You may encrypt your email to this list using the GPG keys of the [Security Response Committee members](#). Encryption using GPG is NOT required to make a disclosure.

### When Should I Report a Vulnerability?

- You think you discovered a potential security vulnerability in Kubernetes
- You are unsure how a vulnerability affects Kubernetes
- You think you discovered a vulnerability in another project that Kubernetes depends on
  - For projects with their own vulnerability reporting and disclosure process, please report it directly there

## When Should I NOT Report a Vulnerability?

- You need help tuning Kubernetes components for security
- You need help applying security related updates
- Your issue is not security related

## Security Vulnerability Response

Each report is acknowledged and analyzed by Security Response Committee members within 3 working days. This will set off the [Security Release Process](#).

Any vulnerability information shared with Security Response Committee stays within Kubernetes project and will not be disseminated to other projects unless it is necessary to get the issue fixed.

As the security issue moves from triage, to identified fix, to release planning we will keep the reporter updated.

## Public Disclosure Timing

A public disclosure date is negotiated by the Kubernetes Security Response Committee and the bug submitter. We prefer to fully disclose the bug as soon as possible once a user mitigation is available. It is reasonable to delay disclosure when the bug or the fix is not yet fully understood, the solution is not well-tested, or for vendor coordination. The timeframe for disclosure is from immediate (especially if it's already publicly known) to a few weeks. For a vulnerability with a straightforward mitigation, we expect report date to disclosure date to be on the order of 7 days. The Kubernetes Security Response Committee holds the final say when setting a disclosure date.

## Official CVE Feed

FEATURE STATE: Kubernetes v1.27 [beta]

This is a community maintained list of official CVEs announced by the Kubernetes Security Response Committee. See [Kubernetes Security and Disclosure Information](#) for more details.

The Kubernetes project publishes a programmatically accessible feed of published security issues in [JSON feed](#) and [RSS feed](#) formats. You can access it by executing the following commands:

- [JSON feed](#)
- [RSS feed](#)

Official Kubernetes CVE List (last updated: 24 May 2024 19:08:31 UTC)

| CVE ID                                                           | Issue Summary                                                                                                                              | CVE GitHub Issue URL    |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|
| <a href="#">CVE-2024-3744</a>                                    | azure-file-csi-driver discloses service account tokens in logs                                                                             | <a href="#">#124759</a> |
| <a href="#">CVE-2024-3177</a>                                    | Bypassing mountable secrets policy imposed by the ServiceAccount admission plugin                                                          | <a href="#">#124336</a> |
| <a href="#">CVE-2023-5528</a>                                    | Insufficient input sanitization in in-tree storage plugin leads to privilege escalation on Windows nodes                                   | <a href="#">#121879</a> |
| <a href="#">CVE-2023-3955</a>                                    | Insufficient input sanitization on Windows nodes leads to privilege escalation                                                             | <a href="#">#119595</a> |
| <a href="#">CVE-2023-3893</a>                                    | Insufficient input sanitization on kubernetes-csi-proxy leads to privilege escalation                                                      | <a href="#">#119594</a> |
| <a href="#">CVE-2023-3676</a>                                    | Insufficient input sanitization on Windows nodes leads to privilege escalation                                                             | <a href="#">#119339</a> |
| <a href="#">CVE-2023-2431</a>                                    | Bypass of seccomp profile enforcement                                                                                                      | <a href="#">#118690</a> |
| <a href="#">CVE-2023-2727</a> ,<br><a href="#">CVE-2023-2728</a> | Bypassing policies imposed by the ImagePolicyWebhook and bypassing mountable secrets policy imposed by the ServiceAccount admission plugin | <a href="#">#118640</a> |
| <a href="#">CVE-2023-2878</a>                                    | secrets-store-csi-driver discloses service account tokens in logs                                                                          | <a href="#">#118419</a> |
| <a href="#">CVE-2022-3294</a>                                    | Node address isn't always verified when proxying                                                                                           | <a href="#">#113757</a> |
| <a href="#">CVE-2022-3162</a>                                    | Unauthorized read of Custom Resources                                                                                                      | <a href="#">#113756</a> |
| <a href="#">CVE-2022-3172</a>                                    | Aggregated API server can cause clients to be redirected (SSRF)                                                                            | <a href="#">#112513</a> |
| <a href="#">CVE-2021-25749</a>                                   | `runAsNonRoot` logic bypass for Windows containers                                                                                         | <a href="#">#112192</a> |
| <a href="#">CVE-2021-25741</a>                                   | Symlink Exchange Can Allow Host Filesystem Access                                                                                          | <a href="#">#104980</a> |
| <a href="#">CVE-2021-25737</a>                                   | Holes in EndpointSlice Validation Enable Host Network Hijack                                                                               | <a href="#">#102106</a> |
| <a href="#">CVE-2021-3121</a>                                    | Processes may panic upon receipt of malicious protobuf messages                                                                            | <a href="#">#101435</a> |
| <a href="#">CVE-2021-25735</a>                                   | Validating Admission Webhook does not observe some previous fields                                                                         | <a href="#">#100096</a> |
| <a href="#">CVE-2020-8554</a>                                    | Man in the middle using LoadBalancer or ExternalIPs                                                                                        | <a href="#">#97076</a>  |
| <a href="#">CVE-2020-8566</a>                                    | Ceph RBD adminSecrets exposed in logs when loglevel >= 4                                                                                   | <a href="#">#95624</a>  |
| <a href="#">CVE-2020-8565</a>                                    | Incomplete fix for CVE-2019-11250 allows for token leak in logs when logLevel >= 9                                                         | <a href="#">#95623</a>  |
| <a href="#">CVE-2020-8564</a>                                    | Docker config secrets leaked when file is malformed and log level >= 4                                                                     | <a href="#">#95622</a>  |
| <a href="#">CVE-2020-8563</a>                                    | Secret leaks in kube-controller-manager when using vSphere provider                                                                        | <a href="#">#95621</a>  |
| <a href="#">CVE-2020-8557</a>                                    | Node disk DOS by writing to container /etc/hosts                                                                                           | <a href="#">#93032</a>  |
| <a href="#">CVE-2020-8559</a>                                    | Privilege escalation from compromised node to cluster                                                                                      | <a href="#">#92914</a>  |
| <a href="#">CVE-2020-8558</a>                                    | Node setting allows for neighboring hosts to bypass localhost boundary                                                                     | <a href="#">#92315</a>  |
| <a href="#">CVE-2020-8555</a>                                    | Half-Blind SSRF in kube-controller-manager                                                                                                 | <a href="#">#91542</a>  |
| <a href="#">CVE-2020-10749</a>                                   |                                                                                                                                            | <a href="#">#91507</a>  |

| CVE ID                           | Issue Summary                                                                                                             | CVE GitHub Issue URL   |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------|------------------------|
|                                  | IPv4 only clusters susceptible to MitM attacks via IPv6 rogue router advertisements                                       |                        |
| <a href="#">CVE-2019-11254</a>   | kube-apiserver Denial of Service vulnerability from malicious YAML payloads                                               | <a href="#">#89535</a> |
| <a href="#">CVE-2020-8552</a>    | apiserver DoS (oom)                                                                                                       | <a href="#">#89378</a> |
| <a href="#">CVE-2020-8551</a>    | Kubelet DoS via API                                                                                                       | <a href="#">#89377</a> |
| <a href="#">CVE-2019-11251</a>   | kubectl cp symlink vulnerability                                                                                          | <a href="#">#87773</a> |
| <a href="#">CVE-2018-1002102</a> | Unvalidated redirect                                                                                                      | <a href="#">#85867</a> |
| <a href="#">CVE-2019-11255</a>   | CSI volume snapshot, cloning and resizing features can result in unauthorized volume data access or mutation              | <a href="#">#85233</a> |
| <a href="#">CVE-2019-11253</a>   | Kubernetes API Server JSON/YAML parsing vulnerable to resource exhaustion attack                                          | <a href="#">#83253</a> |
| <a href="#">CVE-2019-11250</a>   | Bearer tokens are revealed in logs                                                                                        | <a href="#">#81114</a> |
| <a href="#">CVE-2019-11248</a>   | /debug/pprof exposed on kubelet's healthz port                                                                            | <a href="#">#81023</a> |

This feed is auto-refreshing with a noticeable but small lag (minutes to hours) from the time a CVE is announced to the time it is accessible in this feed.

The source of truth of this feed is a set of GitHub Issues, filtered by a controlled and restricted label official-cve-feed. The raw data is stored in a Google Cloud Bucket which is writable only by a small number of trusted members of the Community.

# Node Reference Information

This section contains the following reference topics about nodes:

- the kubelet's [checkpoint API](#)
- a list of [Articles on dockershim Removal and on Using CRI-compatible Runtimes](#)
- [Kubelet Device Manager API Versions](#)
- [Node Labels Populated By The Kubelet](#)
- [Node .status information](#)

You can also read node reference details from elsewhere in the Kubernetes documentation, including:

- [Node Metrics Data](#).
- [CRI Pod & Container Metrics](#).

## Kubelet Checkpoint API

FEATURE STATE: Kubernetes v1.25 [alpha]

Checkpointing a container is the functionality to create a stateful copy of a running container. Once you have a stateful copy of a container, you could move it to a different computer for debugging or similar purposes.

If you move the checkpointed container data to a computer that's able to restore it, that restored container continues to run at exactly the same point it was checkpointed. You can also inspect the saved data, provided that you have suitable tools for doing so.

Creating a checkpoint of a container might have security implications. Typically a checkpoint contains all memory pages of all processes in the checkpointed container. This means that everything that used to be in memory is now available on the local disk. This includes all private data and possibly keys used for encryption. The underlying CRI implementations (the container runtime on that node) should create the checkpoint archive to be only accessible by the root user. It is still important to remember if the checkpoint archive is transferred to another system all memory pages will be readable by the owner of the checkpoint archive.

## Operations

### post checkpoint the specified container

Tell the kubelet to checkpoint a specific container from the specified Pod.

Consult the [Kubelet authentication/authorization reference](#) for more information about how access to the kubelet checkpoint interface is controlled.

The kubelet will request a checkpoint from the underlying [CRI](#) implementation. In the checkpoint request the kubelet will specify the name of the checkpoint archive as `checkpoint-<podFullName>-<containerName>-<timestamp>.tar` and also request to store the checkpoint archive in the checkpoints directory below its root directory (as defined by `--root-dir`). This defaults to `/var/lib/kubelet/checkpoints`.

The checkpoint archive is in *tar* format, and could be listed using an implementation of [tar](#). The contents of the archive depend on the underlying CRI implementation (the container runtime on that node).

## HTTP Request

POST /checkpoint/{namespace}/{pod}/{container}

## Parameters

- **namespace** (*in path*): string, required

[Namespace](#)

- **pod** (*in path*): string, required

[Pod](#)

- **container** (*in path*): string, required

[Container](#)

- **timeout** (*in query*): integer

Timeout in seconds to wait until the checkpoint creation is finished. If zero or no timeout is specified the default [CRI](#) timeout value will be used. Checkpoint creation time depends directly on the used memory of the container. The more memory a container uses the more time is required to create the corresponding checkpoint.

## Response

200: OK

401: Unauthorized

404: Not Found (if the ContainerCheckpoint feature gate is disabled)

404: Not Found (if the specified namespace, pod or container cannot be found)

500: Internal Server Error (if the CRI implementation encounter an error during checkpointing (see error message for further details))

500: Internal Server Error (if the CRI implementation does not implement the checkpoint CRI API (see error message for further details))

# Articles on dockershim Removal and on Using CRI-compatible Runtimes

This is a list of articles and other pages that are either about the Kubernetes' deprecation and removal of *dockershim*, or about using CRI-compatible container runtimes, in connection with that removal.

# Node Labels Populated By The Kubelet

Kubernetes [nodes](#) come pre-populated with a standard set of [labels](#).

You can also set your own labels on nodes, either through the kubelet configuration or using the Kubernetes API.

## Preset labels

The preset labels that Kubernetes sets on nodes are:

- [kubernetes.io/arch](#)
- [kubernetes.io/hostname](#)
- [kubernetes.io/os](#)
- [node.kubernetes.io/instance-type](#) (if known to the kubelet – Kubernetes may not have this information to set the label)
- [topology.kubernetes.io/region](#) (if known to the kubelet – Kubernetes may not have this information to set the label)
- [topology.kubernetes.io/zone](#) (if known to the kubelet – Kubernetes may not have this information to set the label)

### Note:

The value of these labels is cloud provider specific and is not guaranteed to be reliable. For example, the value of `kubernetes.io/hostname` may be the same as the node name in some environments and a different value in other environments.

## What's next

- See [Well-Known Labels, Annotations and Taints](#) for a list of common labels.
- Learn how to [add a label to a node](#).

# Kubelet Configuration Directory Merging

When using the kubelet's `--config-dir` flag to specify a drop-in directory for configuration, there is some specific behavior on how different types are merged.

Here are some examples of how different data types behave during configuration merging:

## Structure Fields

There are two types of structure fields in a YAML structure: singular (or a scalar type) and embedded (structures that contain scalar types). The configuration merging process handles the overriding of singular and embedded struct fields to create a resulting kubelet configuration.

For instance, you may want a baseline kubelet configuration for all nodes, but you may want to customize the address and authorization fields. This can be done as follows:

Main kubelet configuration file contents:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
authorization:
 mode: Webhook
 webhook:
 cacheAuthorizedTTL: "5m"
 cacheUnauthorizedTTL: "30s"
serializeImagePulls: false
address: "192.168.0.1"
```

Contents of a file in --config-dir directory:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
authorization:
 mode: AlwaysAllow
 webhook:
 cacheAuthorizedTTL: "8m"
 cacheUnauthorizedTTL: "45s"
address: "192.168.0.8"
```

The resulting configuration will be as follows:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
serializeImagePulls: false
authorization:
 mode: AlwaysAllow
 webhook:
 cacheAuthorizedTTL: "8m"
 cacheUnauthorizedTTL: "45s"
address: "192.168.0.8"
```

## Lists

You can override the slices/lists values of the kubelet configuration. However, the entire list gets overridden during the merging process. For example, you can override the clusterDNS list as follows:

Main kubelet configuration file contents:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
serializeImagePulls: false
clusterDNS:
```

```
- "192.168.0.9"
- "192.168.0.8"
```

Contents of a file in `--config-dir` directory:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
clusterDNS:
- "192.168.0.2"
- "192.168.0.3"
- "192.168.0.5"
```

The resulting configuration will be as follows:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
serializeImagePulls: false
clusterDNS:
- "192.168.0.2"
- "192.168.0.3"
- "192.168.0.5"
```

## Maps, including Nested Structures

Individual fields in maps, regardless of their value types (boolean, string, etc.), can be selectively overridden. However, for `map[string][]string`, the entire list associated with a specific field gets overridden. Let's understand this better with an example, particularly on fields like `featureGates` and `staticPodURLHeader`:

Main kubelet configuration file contents:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
serializeImagePulls: false
featureGates:
 AllAlpha: false
 MemoryQoS: true
staticPodURLHeader:
 kubelet-api-support:
 - "Authorization: 234APSDFA"
 - "X-Custom-Header: 123"
 custom-static-pod:
 - "Authorization: 223EWRWER"
 - "X-Custom-Header: 456"
```

Contents of a file in `--config-dir` directory:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
featureGates:
 MemoryQoS: false
 KubeletTracing: true
```

```
DynamicResourceAllocation: true
staticPodURLHeader:
 custom-static-pod:
 - "Authorization: 223EWRWER"
 - "X-Custom-Header: 345"
```

The resulting configuration will be as follows:

```
apiVersion: kubelet.config.k8s.io/v1beta1
kind: KubeletConfiguration
port: 20250
serializeImagePulls: false
featureGates:
 AllAlpha: false
 MemoryQoS: false
 KubeletTracing: true
 DynamicResourceAllocation: true
staticPodURLHeader:
 kubelet-api-support:
 - "Authorization: 234APSDFA"
 - "X-Custom-Header: 123"
 custom-static-pod:
 - "Authorization: 223EWRWER"
 - "X-Custom-Header: 345"
```

## Kubelet Device Manager API Versions

This page provides details of version compatibility between the Kubernetes [device plugin API](#), and different versions of Kubernetes itself.

### Compatibility matrix

|                 | v1alpha1 | v1beta1 |
|-----------------|----------|---------|
| Kubernetes 1.21 | -        |         |
| Kubernetes 1.22 | -        |         |
| Kubernetes 1.23 | -        |         |
| Kubernetes 1.24 | -        |         |
| Kubernetes 1.25 | -        |         |
| Kubernetes 1.26 | -        |         |

Key:

- Exactly the same features / API objects in both device plugin API and the Kubernetes version.
- + The device plugin API has features or API objects that may not be present in the Kubernetes cluster, either because the device plugin API has added additional new API calls, or that the server has removed an old API call. However, everything they have in common (most other APIs) will work. Note that alpha APIs may vanish or change significantly between one minor release and the next.

- - The Kubernetes cluster has features the device plugin API can't use, either because server has added additional API calls, or that device plugin API has removed an old API call. However, everything they share in common (most APIs) will work.

## Node Status

The status of a [node](#) in Kubernetes is a critical aspect of managing a Kubernetes cluster. In this article, we'll cover the basics of monitoring and maintaining node status to ensure a healthy and stable cluster.

### Node status fields

A Node's status contains the following information:

- [Addresses](#)
- [Conditions](#)
- [Capacity and Allocatable](#)
- [Info](#)

You can use `kubectl` to view a Node's status and other details:

```
kubectl describe node <insert-node-name-here>
```

Each section of the output is described below.

### Addresses

The usage of these fields varies depending on your cloud provider or bare metal configuration.

- **HostName:** The hostname as reported by the node's kernel. Can be overridden via the `kubelet --hostname-override` parameter.
- **ExternalIP:** Typically the IP address of the node that is externally routable (available from outside the cluster).
- **InternalIP:** Typically the IP address of the node that is routable only within the cluster.

### Conditions

The conditions field describes the status of all Running nodes. Examples of conditions include:

Node conditions, and a description of when each condition applies.

| Node Condition | Description                                                                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ready          | True if the node is healthy and ready to accept pods, False if the node is not healthy and is not accepting pods, and Unknown if the node controller has not heard from the node in the last node-monitor-grace-period (default is 40 seconds) |
| DiskPressure   | True if pressure exists on the disk size—that is, if the disk capacity is low; otherwise False                                                                                                                                                 |
| MemoryPressure | True if pressure exists on the node memory—that is, if the node memory is low; otherwise False                                                                                                                                                 |

| Node Condition     | Description                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| PIDPressure        | True if pressure exists on the processes—that is, if there are too many processes on the node; otherwise False |
| NetworkUnavailable | True if the network for the node is not correctly configured, otherwise False                                  |

### Note:

If you use command-line tools to print details of a cordoned Node, the Condition includes `SchedulingDisabled`. `SchedulingDisabled` is not a Condition in the Kubernetes API; instead, cordoned nodes are marked `Unschedulable` in their spec.

In the Kubernetes API, a node's condition is represented as part of the `.status` of the Node resource. For example, the following JSON structure describes a healthy node:

```
"conditions": [
{
 "type": "Ready",
 "status": "True",
 "reason": "KubeletReady",
 "message": "kubelet is posting ready status",
 "lastHeartbeatTime": "2019-06-05T18:38:35Z",
 "lastTransitionTime": "2019-06-05T11:41:27Z"
}
]
```

When problems occur on nodes, the Kubernetes control plane automatically creates [taints](#) that match the conditions affecting the node. An example of this is when the status of the Ready condition remains Unknown or False for longer than the kube-controller-manager's `NodeMonitorGracePeriod`, which defaults to 40 seconds. This will cause either an `node.kubernetes.io/unreachable` taint, for an Unknown status, or a `node.kubernetes.io/not-ready` taint, for a False status, to be added to the Node.

These taints affect pending pods as the scheduler takes the Node's taints into consideration when assigning a pod to a Node. Existing pods scheduled to the node may be evicted due to the application of `NoExecute` taints. Pods may also have [tolerations](#) that let them schedule to and continue running on a Node even though it has a specific taint.

See [Taint Based Evictions](#) and [Taint Nodes by Condition](#) for more details.

## Capacity and Allocatable

Describes the resources available on the node: CPU, memory, and the maximum number of pods that can be scheduled onto the node.

The fields in the capacity block indicate the total amount of resources that a Node has. The allocatable block indicates the amount of resources on a Node that is available to be consumed by normal Pods.

You may read more about capacity and allocatable resources while learning how to [reserve compute resources](#) on a Node.

## Info

Describes general information about the node, such as kernel version, Kubernetes version (kubelet and kube-proxy version), container runtime details, and which operating system the node uses. The kubelet gathers this information from the node and publishes it into the Kubernetes API.

## Heartbeats

Heartbeats, sent by Kubernetes nodes, help your cluster determine the availability of each node, and to take action when failures are detected.

For nodes there are two forms of heartbeats:

- updates to the `.status` of a Node
- [Lease](#) objects within the kube-node-lease [namespace](#). Each Node has an associated Lease object.

Compared to updates to `.status` of a Node, a Lease is a lightweight resource. Using Leases for heartbeats reduces the performance impact of these updates for large clusters.

The kubelet is responsible for creating and updating the `.status` of Nodes, and for updating their related Leases.

- The kubelet updates the node's `.status` either when there is change in status or if there has been no update for a configured interval. The default interval for `.status` updates to Nodes is 5 minutes, which is much longer than the 40 second default timeout for unreachable nodes.
- The kubelet creates and then updates its Lease object every 10 seconds (the default update interval). Lease updates occur independently from updates to the Node's `.status`. If the Lease update fails, the kubelet retries, using exponential backoff that starts at 200 milliseconds and capped at 7 seconds.

## Networking Reference

This section of the Kubernetes documentation provides reference details of Kubernetes networking.

---

[Protocols for Services](#)

[Ports and Protocols](#)

[Virtual IPs and Service Proxies](#)

## Protocols for Services

If you configure a [Service](#), you can select from any network protocol that Kubernetes supports.

Kubernetes supports the following protocols with Services:

- [SCTP](#)
- [TCP](#) (*the default*)
- [UDP](#)

When you define a Service, you can also specify the [application protocol](#) that it uses.

This document details some special cases, all of them typically using TCP as a transport protocol:

- [HTTP](#) and [HTTPS](#)
- [PROXY protocol](#)
- [TLS](#) termination at the load balancer

## Supported protocols

There are 3 valid values for the protocol of a port for a Service:

### SCTP

FEATURE STATE: Kubernetes v1.20 [stable]

When using a network plugin that supports SCTP traffic, you can use SCTP for most Services. For type: LoadBalancer Services, SCTP support depends on the cloud provider offering this facility. (Most do not).

SCTP is not supported on nodes that run Windows.

### Support for multihomed SCTP associations

The support of multihomed SCTP associations requires that the CNI plugin can support the assignment of multiple interfaces and IP addresses to a Pod.

NAT for multihomed SCTP associations requires special logic in the corresponding kernel modules.

### TCP

You can use TCP for any kind of Service, and it's the default network protocol.

### UDP

You can use UDP for most Services. For type: LoadBalancer Services, UDP support depends on the cloud provider offering this facility.

# Special cases

## HTTP

If your cloud provider supports it, you can use a Service in LoadBalancer mode to configure a load balancer outside of your Kubernetes cluster, in a special mode where your cloud provider's load balancer implements HTTP / HTTPS reverse proxying, with traffic forwarded to the backend endpoints for that Service.

Typically, you set the protocol for the Service to TCP and add an [annotation](#) (usually specific to your cloud provider) that configures the load balancer to handle traffic at the HTTP level. This configuration might also include serving HTTPS (HTTP over TLS) and reverse-proxying plain HTTP to your workload.

### Note:

You can also use an [Ingress](#) to expose HTTP/HTTPS Services.

You might additionally want to specify that the [application protocol](#) of the connection is http or https. Use http if the session from the load balancer to your workload is HTTP without TLS, and use https if the session from the load balancer to your workload uses TLS encryption.

## PROXY protocol

If your cloud provider supports it, you can use a Service set to type: LoadBalancer to configure a load balancer outside of Kubernetes itself, that will forward connections wrapped with the [PROXY protocol](#).

The load balancer then sends an initial series of octets describing the incoming connection, similar to this example (PROXY protocol v1):

```
PROXY TCP4 192.0.2.202 10.0.42.7 12345 7\r\n
```

The data after the proxy protocol preamble are the original data from the client. When either side closes the connection, the load balancer also triggers a connection close and sends any remaining data where feasible.

Typically, you define a Service with the protocol to TCP. You also set an annotation, specific to your cloud provider, that configures the load balancer to wrap each incoming connection in the PROXY protocol.

## TLS

If your cloud provider supports it, you can use a Service set to type: LoadBalancer as a way to set up external reverse proxying, where the connection from client to load balancer is TLS encrypted and the load balancer is the TLS server peer. The connection from the load balancer to your workload can also be TLS, or might be plain text. The exact options available to you depend on your cloud provider or custom Service implementation.

Typically, you set the protocol to TCP and set an annotation (usually specific to your cloud provider) that configures the load balancer to act as a TLS server. You would configure the TLS

identity (as server, and possibly also as a client that connects to your workload) using mechanisms that are specific to your cloud provider.

## Ports and Protocols

When running Kubernetes in an environment with strict network boundaries, such as on-premises datacenter with physical network firewalls or Virtual Networks in Public Cloud, it is useful to be aware of the ports and protocols used by Kubernetes components.

### Control plane

| Protocol | Direction | Port Range | Purpose                 | Used By              |
|----------|-----------|------------|-------------------------|----------------------|
| TCP      | Inbound   | 6443       | Kubernetes API server   | All                  |
| TCP      | Inbound   | 2379-2380  | etcd server client API  | kube-apiserver, etcd |
| TCP      | Inbound   | 10250      | Kubelet API             | Self, Control plane  |
| TCP      | Inbound   | 10259      | kube-scheduler          | Self                 |
| TCP      | Inbound   | 10257      | kube-controller-manager | Self                 |

Although etcd ports are included in control plane section, you can also host your own etcd cluster externally or on custom ports.

### Worker node(s)

| Protocol | Direction | Port Range  | Purpose            | Used By              |
|----------|-----------|-------------|--------------------|----------------------|
| TCP      | Inbound   | 10250       | Kubelet API        | Self, Control plane  |
| TCP      | Inbound   | 10256       | kube-proxy         | Self, Load balancers |
| TCP      | Inbound   | 30000-32767 | NodePort Services† | All                  |

† Default port range for [NodePort Services](#).

All default port numbers can be overridden. When custom ports are used those ports need to be open instead of defaults mentioned here.

One common example is API server port that is sometimes switched to 443. Alternatively, the default port is kept as is and API server is put behind a load balancer that listens on 443 and routes the requests to API server on the default port.

## Virtual IPs and Service Proxies

Every [node](#) in a Kubernetes [cluster](#) runs a [kube-proxy](#) (unless you have deployed your own alternative component in place of kube-proxy).

The kube-proxy component is responsible for implementing a *virtual IP* mechanism for [Services](#) of type other than [ExternalName](#). Each instance of kube-proxy watches the Kubernetes [control plane](#) for the addition and removal of Service and EndpointSlice [objects](#). For each Service, kube-proxy calls appropriate APIs (depending on the kube-proxy mode) to configure the node to capture traffic to the Service's clusterIP and port, and redirect that traffic to one of the Service's endpoints (usually a Pod, but possibly an arbitrary user-provided IP address). A control loop

ensures that the rules on each node are reliably synchronized with the Service and EndpointSlice state as indicated by the API server.

### **Virtual IP mechanism for Services, using iptables mode**

A question that pops up every now and then is why Kubernetes relies on proxying to forward inbound traffic to backends. What about other approaches? For example, would it be possible to configure DNS records that have multiple A values (or AAAA for IPv6), and rely on round-robin name resolution?

There are a few reasons for using proxying for Services:

- There is a long history of DNS implementations not respecting record TTLs, and caching the results of name lookups after they should have expired.
- Some apps do DNS lookups only once and cache the results indefinitely.
- Even if apps and libraries did proper re-resolution, the low or zero TTLs on the DNS records could impose a high load on DNS that then becomes difficult to manage.

Later in this page you can read about how various kube-proxy implementations work. Overall, you should note that, when running kube-proxy, kernel level rules may be modified (for example, iptables rules might get created), which won't get cleaned up, in some cases until you reboot. Thus, running kube-proxy is something that should only be done by an administrator which understands the consequences of having a low level, privileged network proxying service on a computer. Although the kube-proxy executable supports a cleanup function, this function is not an official feature and thus is only available to use as-is.

Some of the details in this reference refer to an example: the backend [Pods](#) for a stateless image-processing workloads, running with three replicas. Those replicas are fungible—frontends do not care which backend they use. While the actual Pods that compose the backend set may change, the frontend clients should not need to be aware of that, nor should they need to keep track of the set of backends themselves.

## **Proxy modes**

The kube-proxy starts up in different modes, which are determined by its configuration.

On Linux nodes, the available modes for kube-proxy are:

### [iptables](#)

A mode where the kube-proxy configures packet forwarding rules using iptables.

### [ipvs](#)

a mode where the kube-proxy configures packet forwarding rules using ipvs.

### [nftables](#)

a mode where the kube-proxy configures packet forwarding rules using nftables.

There is only one mode available for kube-proxy on Windows:

### [kernel-space](#)

a mode where the kube-proxy configures packet forwarding rules in the Windows kernel

## **iptables proxy mode**

*This proxy mode is only available on Linux nodes.*

In this mode, kube-proxy configures packet forwarding rules using the iptables API of the kernel netfilter subsystem. For each endpoint, it installs iptables rules which, by default, select a backend Pod at random.

## Example

As an example, consider the image processing application described [earlier](#) in the page. When the backend Service is created, the Kubernetes control plane assigns a virtual IP address, for example 10.0.0.1. For this example, assume that the Service port is 1234. All of the kube-proxy instances in the cluster observe the creation of the new Service.

When kube-proxy on a node sees a new Service, it installs a series of iptables rules which redirect from the virtual IP address to more iptables rules, defined per Service. The per-Service rules link to further rules for each backend endpoint, and the per- endpoint rules redirect traffic (using destination NAT) to the backends.

When a client connects to the Service's virtual IP address the iptables rule kicks in. A backend is chosen (either based on session affinity or randomly) and packets are redirected to the backend without rewriting the client IP address.

This same basic flow executes when traffic comes in through a node-port or through a load-balancer, though in those cases the client IP address does get altered.

## Optimizing iptables mode performance

In iptables mode, kube-proxy creates a few iptables rules for every Service, and a few iptables rules for each endpoint IP address. In clusters with tens of thousands of Pods and Services, this means tens of thousands of iptables rules, and kube-proxy may take a long time to update the rules in the kernel when Services (or their EndpointSlices) change. You can adjust the syncing behavior of kube-proxy via options in the [iptables section](#) of the kube-proxy [configuration file](#) (which you specify via kube-proxy --config <path>):

```
...
iptables:
 minSyncPeriod: 1s
 syncPeriod: 30s
...
```

### minSyncPeriod

The minSyncPeriod parameter sets the minimum duration between attempts to resynchronize iptables rules with the kernel. If it is 0s, then kube-proxy will always immediately synchronize the rules every time any Service or Endpoint changes. This works fine in very small clusters, but it results in a lot of redundant work when lots of things change in a small time period. For example, if you have a Service backed by a [Deployment](#) with 100 pods, and you delete the Deployment, then with minSyncPeriod: 0s, kube-proxy would end up removing the Service's endpoints from the iptables rules one by one, for a total of 100 updates. With a larger minSyncPeriod, multiple Pod deletion events would get aggregated together, so kube-proxy might instead end up making, say, 5 updates, each removing 20 endpoints, which will be much more efficient in terms of CPU, and result in the full set of changes being synchronized faster.

The larger the value of `minSyncPeriod`, the more work that can be aggregated, but the downside is that each individual change may end up waiting up to the full `minSyncPeriod` before being processed, meaning that the iptables rules spend more time being out-of-sync with the current API server state.

The default value of 1s should work well in most clusters, but in very large clusters it may be necessary to set it to a larger value. Especially, if kube-proxy's `sync_proxy_rules_duration_seconds` metric indicates an average time much larger than 1 second, then bumping up `minSyncPeriod` may make updates more efficient.

### Updating legacy `minSyncPeriod` configuration

Older versions of kube-proxy updated all the rules for all Services on every sync; this led to performance issues (update lag) in large clusters, and the recommended solution was to set a larger `minSyncPeriod`. Since Kubernetes v1.28, the iptables mode of kube-proxy uses a more minimal approach, only making updates where Services or EndpointSlices have actually changed.

If you were previously overriding `minSyncPeriod`, you should try removing that override and letting kube-proxy use the default value (1s) or at least a smaller value than you were using before upgrading.

If you are not running kube-proxy from Kubernetes 1.30, check the behavior and associated advice for the version that you are actually running.

### `syncPeriod`

The `syncPeriod` parameter controls a handful of synchronization operations that are not directly related to changes in individual Services and EndpointSlices. In particular, it controls how quickly kube-proxy notices if an external component has interfered with kube-proxy's iptables rules. In large clusters, kube-proxy also only performs certain cleanup operations once every `syncPeriod` to avoid unnecessary work.

For the most part, increasing `syncPeriod` is not expected to have much impact on performance, but in the past, it was sometimes useful to set it to a very large value (eg, 1h). This is no longer recommended, and is likely to hurt functionality more than it improves performance.

## IPVS proxy mode

*This proxy mode is only available on Linux nodes.*

In ipvs mode, kube-proxy uses the kernel IPVS and iptables APIs to create rules to redirect traffic from Service IPs to endpoint IPs.

The IPVS proxy mode is based on netfilter hook function that is similar to iptables mode, but uses a hash table as the underlying data structure and works in the kernel space. That means kube-proxy in IPVS mode redirects traffic with lower latency than kube-proxy in iptables mode, with much better performance when synchronizing proxy rules. Compared to the iptables proxy mode, IPVS mode also supports a higher throughput of network traffic.

IPVS provides more options for balancing traffic to backend Pods; these are:

- rr (Round Robin): Traffic is equally distributed amongst the backing servers.

- **wrr** (Weighted Round Robin): Traffic is routed to the backing servers based on the weights of the servers. Servers with higher weights receive new connections and get more requests than servers with lower weights.
- **lc** (Least Connection): More traffic is assigned to servers with fewer active connections.
- **wlc** (Weighted Least Connection): More traffic is routed to servers with fewer connections relative to their weights, that is, connections divided by weight.
- **lblc** (Locality based Least Connection): Traffic for the same IP address is sent to the same backing server if the server is not overloaded and available; otherwise the traffic is sent to servers with fewer connections, and keep it for future assignment.
- **lblcr** (Locality Based Least Connection with Replication): Traffic for the same IP address is sent to the server with least connections. If all the backing servers are overloaded, it picks up one with fewer connections and add it to the target set. If the target set has not changed for the specified time, the most loaded server is removed from the set, in order to avoid high degree of replication.
- **sh** (Source Hashing): Traffic is sent to a backing server by looking up a statically assigned hash table based on the source IP addresses.
- **dh** (Destination Hashing): Traffic is sent to a backing server by looking up a statically assigned hash table based on their destination addresses.
- **sed** (Shortest Expected Delay): Traffic forwarded to a backing server with the shortest expected delay. The expected delay is  $(C + 1) / U$  if sent to a server, where  $C$  is the number of connections on the server and  $U$  is the fixed service rate (weight) of the server.
- **nq** (Never Queue): Traffic is sent to an idle server if there is one, instead of waiting for a fast one; if all servers are busy, the algorithm falls back to the sed behavior.

#### **Note:**

To run kube-proxy in IPVS mode, you must make IPVS available on the node before starting kube-proxy.

When kube-proxy starts in IPVS proxy mode, it verifies whether IPVS kernel modules are available. If the IPVS kernel modules are not detected, then kube-proxy exits with an error.

### **Virtual IP address mechanism for Services, using IPVS mode**

#### **nftables proxy mode**

FEATURE STATE: Kubernetes v1.29 [alpha]

*This proxy mode is only available on Linux nodes.*

In this mode, kube-proxy configures packet forwarding rules using the nftables API of the kernel netfilter subsystem. For each endpoint, it installs nftables rules which, by default, select a backend Pod at random.

The nftables API is the successor to the iptables API, and although it is designed to provide better performance and scalability than iptables, the kube-proxy nftables mode is still under heavy development as of 1.30 and is not necessarily expected to outperform the other Linux modes at this time.

## kernel-space proxy mode

*This proxy mode is only available on Windows nodes.*

The kube-proxy configures packet filtering rules in the Windows *Virtual Filtering Platform* (VFP), an extension to Windows vSwitch. These rules process encapsulated packets within the node-level virtual networks, and rewrite packets so that the destination IP address (and layer 2 information) is correct for getting the packet routed to the correct destination. The Windows VFP is analogous to tools such as Linux nftables or iptables. The Windows VFP extends the *Hyper-V Switch*, which was initially implemented to support virtual machine networking.

When a Pod on a node sends traffic to a virtual IP address, and the kube-proxy selects a Pod on a different node as the load balancing target, the kernel-space proxy mode rewrites that packet to be destined to the target backend Pod. The Windows *Host Networking Service* (HNS) ensures that packet rewriting rules are configured so that the return traffic appears to come from the virtual IP address and not the specific backend Pod.

## Direct server return for kernel-space mode

FEATURE STATE: Kubernetes v1.14 [alpha]

As an alternative to the basic operation, a node that hosts the backend Pod for a Service can apply the packet rewriting directly, rather than placing this burden on the node where the client Pod is running. This is called *direct server return*.

To use this, you must run kube-proxy with the `--enable-dsr` command line argument **and** enable the WinDSR [feature gate](#).

Direct server return also optimizes the case for Pod return traffic even when both Pods are running on the same node.

## Session affinity

In these proxy models, the traffic bound for the Service's IP:Port is proxied to an appropriate backend without the clients knowing anything about Kubernetes or Services or Pods.

If you want to make sure that connections from a particular client are passed to the same Pod each time, you can select the session affinity based on the client's IP addresses by setting `.spec.sessionAffinity` to `ClientIP` for a Service (the default is `None`).

## Session stickiness timeout

You can also set the maximum session sticky time by setting `.spec.sessionAffinityConfig.clientIP.timeoutSeconds` appropriately for a Service. (the default value is 10800, which works out to be 3 hours).

## Note:

On Windows, setting the maximum session sticky time for Services is not supported.

## IP address assignment to Services

Unlike Pod IP addresses, which actually route to a fixed destination, Service IPs are not actually answered by a single host. Instead, kube-proxy uses packet processing logic (such as Linux iptables) to define *virtual* IP addresses which are transparently redirected as needed.

When clients connect to the VIP, their traffic is automatically transported to an appropriate endpoint. The environment variables and DNS for Services are actually populated in terms of the Service's virtual IP address (and port).

## Avoiding collisions

One of the primary philosophies of Kubernetes is that you should not be exposed to situations that could cause your actions to fail through no fault of your own. For the design of the Service resource, this means not making you choose your own IP address if that choice might collide with someone else's choice. That is an isolation failure.

In order to allow you to choose an IP address for your Services, we must ensure that no two Services can collide. Kubernetes does that by allocating each Service its own IP address from within the service-cluster-ip-range CIDR range that is configured for the [API Server](#).

## IP address allocation tracking

To ensure each Service receives a unique IP address, an internal allocator atomically updates a global allocation map in [etcd](#) prior to creating each Service. The map object must exist in the registry for Services to get IP address assignments, otherwise creations will fail with a message indicating an IP address could not be allocated.

In the control plane, a background controller is responsible for creating that map (needed to support migrating from older versions of Kubernetes that used in-memory locking). Kubernetes also uses controllers to check for invalid assignments (for example: due to administrator intervention) and for cleaning up allocated IP addresses that are no longer used by any Services.

## IP address allocation tracking using the Kubernetes API

FEATURE STATE: Kubernetes v1.27 [alpha]

If you enable the MultiCIDRServiceAllocator [feature gate](#) and the [networking.k8s.io/v1alpha1 API group](#), the control plane replaces the existing etcd allocator with a revised implementation that uses IPAddress and ServiceCIDR objects instead of an internal global allocation map. Each cluster IP address associated to a Service then references an IPAddress object.

Enabling the feature gate also replaces a background controller with an alternative that handles the IPAddress objects and supports migration from the old allocator model. Kubernetes 1.30 does not support migrating from IPAddress objects to the internal allocation map.

One of the main benefits of the revised allocator is that it removes the size limitations for the IP address range that can be used for the cluster IP address of Services. With MultiCIDRServiceAllocator enabled, there are no limitations for IPv4, and for IPv6 you can use IP address netmasks that are a /64 or smaller (as opposed to /108 with the legacy implementation).

Making IP address allocations available via the API means that you as a cluster administrator can allow users to inspect the IP addresses assigned to their Services. Kubernetes extensions, such as the [Gateway API](#), can use the IPAddress API to extend Kubernetes' inherent networking capabilities.

Here is a brief example of a user querying for IP addresses:

```
kubectl get services
```

| NAME       | TYPE      | CLUSTER-IP      | EXTERNAL-IP | PORT(S) | AGE  |
|------------|-----------|-----------------|-------------|---------|------|
| kubernetes | ClusterIP | 2001:db8:1:2::1 | <none>      | 443/TCP | 3d1h |

```
kubectl get ipaddresses
```

| NAME            | PARENTREF                     |
|-----------------|-------------------------------|
| 2001:db8:1:2::1 | services/default/kubernetes   |
| 2001:db8:1:2::a | services/kube-system/kube-dns |

Kubernetes also allow users to dynamically define the available IP ranges for Services using ServiceCIDR objects. During bootstrap, a default ServiceCIDR object named kubernetes is created from the value of the --service-cluster-ip-range command line argument to kube-apiserver:

```
kubectl get servicecidrs
```

| NAME       | CIDRS        | AGE |
|------------|--------------|-----|
| kubernetes | 10.96.0.0/28 | 17m |

Users can create or delete new ServiceCIDR objects to manage the available IP ranges for Services:

```
cat <<'EOF' | kubectl apply -f -
apiVersion: networking.k8s.io/v1alpha1
kind: ServiceCIDR
metadata:
 name: newservicecidr
spec:
 cidrs:
 - 10.96.0.0/24
EOF
```

```
servicecidr.networking.k8s.io/newcidr1 created
```

```
kubectl get servicecidrs
```

| NAME           | CIDRS        | AGE |
|----------------|--------------|-----|
| kubernetes     | 10.96.0.0/28 | 17m |
| newservicecidr | 10.96.0.0/24 | 7m  |

## IP address ranges for Service virtual IP addresses

FEATURE STATE: Kubernetes v1.26 [stable]

Kubernetes divides the ClusterIP range into two bands, based on the size of the configured service-cluster-ip-range by using the following formula  $\min(\max(16, \text{cidrSize} / 16), 256)$ . That formula paraphrases as *never less than 16 or more than 256, with a graduated step function between them*.

Kubernetes prefers to allocate dynamic IP addresses to Services by choosing from the upper band, which means that if you want to assign a specific IP address to a type: ClusterIP Service, you should manually assign an IP address from the **lower** band. That approach reduces the risk of a conflict over allocation.

## Traffic policies

You can set the `.spec.internalTrafficPolicy` and `.spec.externalTrafficPolicy` fields to control how Kubernetes routes traffic to healthy (“ready”) backends.

### Internal traffic policy

FEATURE STATE: Kubernetes v1.26 [stable]

You can set the `.spec.internalTrafficPolicy` field to control how traffic from internal sources is routed. Valid values are Cluster and Local. Set the field to Cluster to route internal traffic to all ready endpoints and Local to only route to ready node-local endpoints. If the traffic policy is Local and there are no node-local endpoints, traffic is dropped by kube-proxy.

### External traffic policy

You can set the `.spec.externalTrafficPolicy` field to control how traffic from external sources is routed. Valid values are Cluster and Local. Set the field to Cluster to route external traffic to all ready endpoints and Local to only route to ready node-local endpoints. If the traffic policy is Local and there are no node-local endpoints, the kube-proxy does not forward any traffic for the relevant Service.

If Cluster is specified all nodes are eligible load balancing targets *as long as* the node is not being deleted and kube-proxy is healthy. In this mode: load balancer health checks are configured to target the service proxy's readiness port and path. In the case of kube-proxy this evaluates to: `$_NODE_IP:10256/healthz`. kube-proxy will return either an HTTP code 200 or 503. kube-proxy's load balancer health check endpoint returns 200 if:

1. kube-proxy is healthy, meaning:
  - it's able to progress programming the network and isn't timing out while doing so (the timeout is defined to be:  $2 \times \text{iptables.syncPeriod}$ ); and
2. the node is not being deleted (there is no deletion timestamp set for the Node).

The reason why kube-proxy returns 503 and marks the node as not eligible when it's being deleted, is because kube-proxy supports connection draining for terminating nodes. A couple of important things occur from the point of view of a Kubernetes-managed load balancer when a node *is being* / *is* deleted.

While deleting:

- kube-proxy will start failing its readiness probe and essentially mark the node as not eligible for load balancer traffic. The load balancer health check failing causes load balancers which support connection draining to allow existing connections to terminate, and block new connections from establishing.

When deleted:

- The service controller in the Kubernetes cloud controller manager removes the node from the referenced set of eligible targets. Removing any instance from the load balancer's set of backend targets immediately terminates all connections. This is also the reason kube-proxy first fails the health check while the node is deleting.

It's important to note for Kubernetes vendors that if any vendor configures the kube-proxy readiness probe as a liveness probe: that kube-proxy will start restarting continuously when a node is deleting until it has been fully deleted. kube-proxy exposes a `/livez` path which, as opposed to the `/healthz` one, does **not** consider the Node's deleting state and only its progress programming the network. `/livez` is therefore the recommended path for anyone looking to define a `LivenessProbe` for kube-proxy.

Users deploying kube-proxy can inspect both the readiness / liveness state by evaluating the metrics: `proxy_livez_total` / `proxy_healthz_total`. Both metrics publish two series, one with the 200 label and one with the 503 one.

For Local Services: kube-proxy will return 200 if

1. kube-proxy is healthy/ready, and
2. has a local endpoint on the node in question.

Node deletion does **not** have an impact on kube-proxy's return code for what concerns load balancer health checks. The reason for this is: deleting nodes could end up causing an ingress outage should all endpoints simultaneously be running on said nodes.

The Kubernetes project recommends that cloud provider integration code configures load balancer health checks that target the service proxy's `healthz` port. If you are using or implementing your own virtual IP implementation, that people can use instead of kube-proxy, you should set up a similar health checking port with logic that matches the kube-proxy implementation.

## Traffic to terminating endpoints

FEATURE STATE: Kubernetes v1.28 [stable]

If the `ProxyTerminatingEndpoints` [feature gate](#) is enabled in kube-proxy and the traffic policy is Local, that node's kube-proxy uses a more complicated algorithm to select endpoints for a Service. With the feature enabled, kube-proxy checks if the node has local endpoints and whether or not all the local endpoints are marked as terminating. If there are local endpoints and **all** of them are terminating, then kube-proxy will forward traffic to those terminating endpoints. Otherwise, kube-proxy will always prefer forwarding traffic to endpoints that are not terminating.

This forwarding behavior for terminating endpoints exist to allow NodePort and LoadBalancer Services to gracefully drain connections when using `externalTrafficPolicy: Local`.

As a deployment goes through a rolling update, nodes backing a load balancer may transition from N to 0 replicas of that deployment. In some cases, external load balancers can send traffic to a node with 0 replicas in between health check probes. Routing traffic to terminating endpoints ensures that Node's that are scaling down Pods can gracefully receive and drain traffic to those terminating Pods. By the time the Pod completes termination, the external load balancer should have seen the node's health check failing and fully removed the node from the backend pool.

## Traffic Distribution

FEATURE STATE: Kubernetes v1.30 [alpha]

The `spec.trafficDistribution` field within a Kubernetes Service allows you to express preferences for how traffic should be routed to Service endpoints. Implementations like kube-proxy use the `spec.trafficDistribution` field as a guideline. The behavior associated with a given preference may subtly differ between implementations.

### PreferClose with kube-proxy

For kube-proxy, this means prioritizing sending traffic to endpoints within the same zone as the client. The EndpointSlice controller updates EndpointSlices with hints to communicate this preference, which kube-proxy then uses for routing decisions. If a client's zone does not have any available endpoints, traffic will be routed cluster-wide for that client.

In the absence of any value for `trafficDistribution`, the default routing strategy for kube-proxy is to distribute traffic to any endpoint in the cluster.

### Comparison with `service.kubernetes.io/topology-mode: Auto`

The `trafficDistribution` field with `PreferClose` and the `service.kubernetes.io/topology-mode: Auto` annotation both aim to prioritize same-zone traffic. However, there are key differences in their approaches:

- `service.kubernetes.io/topology-mode: Auto`: Attempts to distribute traffic proportionally across zones based on allocatable CPU resources. This heuristic includes safeguards (such as the [fallback behavior](#) for small numbers of endpoints) and could lead to the feature being disabled in certain scenarios for load-balancing reasons. This approach sacrifices some predictability in favor of potential load balancing.
- `trafficDistribution: PreferClose`: This approach aims to be slightly simpler and more predictable: "If there are endpoints in the zone, they will receive all traffic for that zone, if there are no endpoints in a zone, the traffic will be distributed to other zones". While the approach may offer more predictability, it does mean that you are in control of managing a [potential overload](#).

If the `service.kubernetes.io/topology-mode` annotation is set to `Auto`, it will take precedence over `trafficDistribution`. (The annotation may be deprecated in the future in favour of the `trafficDistribution` field).

## Interaction with Traffic Policies

When compared to the `trafficDistribution` field, the traffic policy fields (`externalTrafficPolicy` and `internalTrafficPolicy`) are meant to offer a stricter traffic locality requirements. Here's how `trafficDistribution` interacts with them:

- **Precedence of Traffic Policies:** For a given Service, if a traffic policy (`externalTrafficPolicy` or `internalTrafficPolicy`) is set to `Local`, it takes precedence over `trafficDistribution: PreferClose` for the corresponding traffic type (external or internal, respectively).
- **trafficDistribution Influence:** For a given Service, if a traffic policy (`externalTrafficPolicy` or `internalTrafficPolicy`) is set to `Cluster` (the default), or if the fields are not set, then `trafficDistribution: PreferClose` guides the routing behavior for the corresponding traffic type (external or internal, respectively). This means that an attempt will be made to route traffic to an endpoint that is in the same zone as the client.

## Considerations for using traffic distribution control

- **Increased Probability of Overloaded Endpoints:** The `PreferClose` heuristic will attempt to route traffic to the closest healthy endpoints instead of spreading that traffic evenly across all endpoints. If you do not have a sufficient number of endpoints within a zone, they may become overloaded. This is especially likely if incoming traffic is not proportionally distributed across zones. To mitigate this, consider the following strategies:
  - [Pod Topology Spread Constraints](#): Use Pod Topology Spread Constraints to distribute your pods more evenly across zones.
  - **Zone-specific Deployments:** If you expect to see skewed traffic patterns, create a separate Deployment for each zone. This approach allows the separate workloads to scale independently. There are also workload management addons available from the ecosystem, outside the Kubernetes project itself, that can help here.
- **Implementation-specific behavior:** Each dataplane implementation may handle this field slightly differently. If you're using an implementation other than kube-proxy, refer the documentation specific to that implementation to understand how this field is being handled.

## What's next

To learn more about Services, read [Connecting Applications with Services](#).

You can also:

- Read about [Services](#) as a concept
- Read about [Ingresses](#) as a concept
- Read the [API reference](#) for the Service API

## Setup tools

---

# Kubeadm

Kubeadm is a tool built to provide `kubeadm init` and `kubeadm join` as best-practice "fast paths" for creating Kubernetes clusters.

kubeadm performs the actions necessary to get a minimum viable cluster up and running. By design, it cares only about bootstrapping, not about provisioning machines. Likewise, installing various nice-to-have addons, like the Kubernetes Dashboard, monitoring solutions, and cloud-specific addons, is not in scope.

Instead, we expect higher-level and more tailored tooling to be built on top of kubeadm, and ideally, using kubeadm as the basis of all deployments will make it easier to create conformant clusters.

## How to install

To install kubeadm, see the [installation guide](#).

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to bootstrap a Kubernetes worker node and join it to the cluster
- [kubeadm upgrade](#) to upgrade a Kubernetes cluster to a newer version
- [kubeadm config](#) if you initialized your cluster using kubeadm v1.7.x or lower, to configure your cluster for kubeadm upgrade
- [kubeadm token](#) to manage tokens for kubeadm join
- [kubeadm reset](#) to revert any changes made to this host by `kubeadm init` or `kubeadm join`
- [kubeadm certs](#) to manage Kubernetes certificates
- [kubeadm kubeconfig](#) to manage kubeconfig files
- [kubeadm version](#) to print the kubeadm version
- [kubeadm alpha](#) to preview a set of features made available for gathering feedback from the community

## kubeadm init

This command initializes a Kubernetes control-plane node.

Run this command in order to set up the Kubernetes control plane

### Synopsis

Run this command in order to set up the Kubernetes control plane

The "init" command executes the following phases:

|           |                        |
|-----------|------------------------|
| preflight | Run pre-flight checks  |
| certs     | Certificate generation |

|                             |                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------|
| /ca                         | Generate the self-signed Kubernetes CA to provision identities for other Kubernetes components       |
| /apiserver                  | Generate the certificate for serving the Kubernetes API                                              |
| /apiserver-kubelet-client   | Generate the certificate for the API server to connect to kubelet                                    |
| /front-proxy-ca             | Generate the self-signed CA to provision identities for front proxy                                  |
| /front-proxy-client         | Generate the certificate for the front proxy client                                                  |
| /etcd-ca                    | Generate the self-signed CA to provision identities for etcd                                         |
| /etcd-server                | Generate the certificate for serving etcd                                                            |
| /etcd-peer                  | Generate the certificate for etcd nodes to communicate with each other                               |
| /etcd-healthcheck-client    | Generate the certificate for liveness probes to healthcheck etcd                                     |
| /apiserver-etcd-client      | Generate the certificate the apiserver uses to access etcd                                           |
| /sa                         | Generate a private key for signing service account tokens along with its public key                  |
| kubeconfig                  | Generate all kubeconfig files necessary to establish the control plane and the admin kubeconfig file |
| /admin                      | Generate a kubeconfig file for the admin to use and for kubeadm itself                               |
| /super-admin                | Generate a kubeconfig file for the super-admin                                                       |
| /kubelet                    | Generate a kubeconfig file for the kubelet to use *only* for cluster bootstrapping purposes          |
| /controller-manager         | Generate a kubeconfig file for the controller manager to use                                         |
| /scheduler                  | Generate a kubeconfig file for the scheduler to use                                                  |
| etcd                        | Generate static Pod manifest file for local etcd                                                     |
| /local                      | Generate the static Pod manifest file for a local, single-node local etcd instance                   |
| control-plane               | Generate all static Pod manifest files necessary to establish the control plane                      |
| /apiserver                  | Generates the kube-apiserver static Pod manifest                                                     |
| /controller-manager         | Generates the kube-controller-manager static Pod manifest                                            |
| /scheduler                  | Generates the kube-scheduler static Pod manifest                                                     |
| kubelet-start               | Write kubelet settings and (re)start the kubelet                                                     |
| upload-config               | Upload the kubeadm and kubelet configuration to a ConfigMap                                          |
| /kubeadm                    | Upload the kubeadm ClusterConfiguration to a ConfigMap                                               |
| /kubelet                    | Upload the kubelet component config to a ConfigMap                                                   |
| upload-certs                | Upload certificates to kubeadm-certs                                                                 |
| mark-control-plane          | Mark a node as a control-plane                                                                       |
| bootstrap-token             | Generates bootstrap tokens used to join a node to a cluster                                          |
| kubelet-finalize            | Updates settings relevant to the kubelet after TLS bootstrap                                         |
| /experimental-cert-rotation | Enable kubelet client certificate rotation                                                           |
| addon                       | Install required addons for passing conformance tests                                                |
| /coredns                    | Install the CoreDNS addon to a Kubernetes cluster                                                    |
| /kube-proxy                 | Install the kube-proxy addon to a Kubernetes cluster                                                 |
| show-join-command           | Show the join command for control-plane and worker node                                              |

kubeadm init [flags]

## Options

|                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------|
| --apiserver-advertise-address string                                                                                   |
| The IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |

|                                                                                                                                                                                                                                                                                                                                                                                                                    |                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| <code>--apiserver-bind-port int32</code>                                                                                                                                                                                                                                                                                                                                                                           | Default: 6443                  |
| Port for the API Server to bind to.                                                                                                                                                                                                                                                                                                                                                                                |                                |
| <code>--apiserver-cert-extra-sans strings</code>                                                                                                                                                                                                                                                                                                                                                                   |                                |
| Optional extra Subject Alternative Names (SANs) to use for the API Server serving certificate. Can be both IP addresses and DNS names.                                                                                                                                                                                                                                                                             |                                |
| <code>--cert-dir string</code>                                                                                                                                                                                                                                                                                                                                                                                     | Default: "/etc/kubernetes/pki" |
| The path where to save and store the certificates.                                                                                                                                                                                                                                                                                                                                                                 |                                |
| <code>--certificate-key string</code>                                                                                                                                                                                                                                                                                                                                                                              |                                |
| Key used to encrypt the control-plane certificates in the kubeadm-certs Secret. The certificate key is a hex encoded string that is an AES key of size 32 bytes.                                                                                                                                                                                                                                                   |                                |
| <code>--config string</code>                                                                                                                                                                                                                                                                                                                                                                                       |                                |
| Path to a kubeadm configuration file.                                                                                                                                                                                                                                                                                                                                                                              |                                |
| <code>--control-plane-endpoint string</code>                                                                                                                                                                                                                                                                                                                                                                       |                                |

| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --pod-network-cidr string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Specify range of IP addresses for the pod network. If set, the control plane will automatically allocate CIDRs for every node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Don't print the key used to encrypt the control-plane certificates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| --skip-phases strings                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| List of phases to be skipped                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --skip-token-print                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Skip printing of the default bootstrap token generated by 'kubeadm init'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --token string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The token to use for establishing bidirectional trust between nodes and control-plane nodes. The format is [a-z0-9]{6}.[a-z0-9]{16} - e.g. abcdef.0123456789abcdef |
| --token-ttl duration    Default: 24h0m0s                                                                                                                           |
| The duration before the token is automatically deleted (e.g. 1s, 2m, 3h). If set to '0', the token will never expire                                               |
| --upload-certs                                                                                                                                                     |
| Upload control-plane certificates to the kubeadm-certs Secret.                                                                                                     |

## Options inherited from parent commands

|                                                             |

| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## Init workflow

kubeadm init bootstraps a Kubernetes control-plane node by executing the following steps:

1. Runs a series of pre-flight checks to validate the system state before making changes. Some checks only trigger warnings, others are considered errors and will exit kubeadm until the problem is corrected or the user specifies `--ignore-preflight-errors=<list-of-errors>`.
2. Generates a self-signed CA to set up identities for each component in the cluster. The user can provide their own CA cert and/or key by dropping it in the cert directory configured via `--cert-dir` (`/etc/kubernetes/pki` by default). The APIServer certs will have additional SAN entries for any `--apiserver-cert-extra-sans` arguments, lowercased if necessary.
3. Writes kubeconfig files in `/etc/kubernetes/` for the kubelet, the controller-manager and the scheduler to use to connect to the API server, each with its own identity. Also additional kubeconfig files are written, for kubeadm as administrative entity (`admin.conf`) and for a super admin user that can bypass RBAC (`super-admin.conf`).
4. Generates static Pod manifests for the API server, controller-manager and scheduler. In case an external etcd is not provided, an additional static Pod manifest is generated for etcd.

Static Pod manifests are written to `/etc/kubernetes/manifests`; the kubelet watches this directory for Pods to create on startup.

Once control plane Pods are up and running, the kubeadm init sequence can continue.

5. Apply labels and taints to the control-plane node so that no additional workloads will run there.

- Generates the token that additional nodes can use to register themselves with a control-
6. plane in the future. Optionally, the user can provide a token via `--token`, as described in the [kubeadm token](#) docs.
  7. Makes all the necessary configurations for allowing node joining with the [Bootstrap Tokens](#) and [TLS Bootstrap](#) mechanism:
    - Write a ConfigMap for making available all the information required for joining, and set up related RBAC access rules.
    - Let Bootstrap Tokens access the CSR signing API.
    - Configure auto-approval for new CSR requests.

See [kubeadm join](#) for additional info.

8. Installs a DNS server (CoreDNS) and the kube-proxy addon components via the API server. In Kubernetes version 1.11 and later CoreDNS is the default DNS server. Please note that although the DNS server is deployed, it will not be scheduled until CNI is installed.

### **Warning:**

kube-dns usage with kubeadm is deprecated as of v1.18 and is removed in v1.21.

## **Using init phases with kubeadm**

Kubeadm allows you to create a control-plane node in phases using the `kubeadm init phase` command.

To view the ordered list of phases and sub-phases you can call `kubeadm init --help`. The list will be located at the top of the help screen and each phase will have a description next to it. Note that by calling `kubeadm init` all of the phases and sub-phases will be executed in this exact order.

Some phases have unique flags, so if you want to have a look at the list of available options add `--help`, for example:

```
sudo kubeadm init phase control-plane controller-manager --help
```

You can also use `--help` to see the list of sub-phases for a certain parent phase:

```
sudo kubeadm init phase control-plane --help
```

`kubeadm init` also exposes a flag called `--skip-phases` that can be used to skip certain phases. The flag accepts a list of phase names and the names can be taken from the above ordered list.

An example:

```
sudo kubeadm init phase control-plane all --config=configfile.yaml
sudo kubeadm init phase etcd local --config=configfile.yaml
you can now modify the control plane and etcd manifest files
sudo kubeadm init --skip-phases=control-plane,etcd --config=configfile.yaml
```

What this example would do is write the manifest files for the control plane and etcd in `/etc/kubernetes/manifests` based on the configuration in `configfile.yaml`. This allows you to modify the files and then skip these phases using `--skip-phases`. By calling the last command you will create a control plane node with the custom manifest files.

FEATURE STATE: Kubernetes v1.22 [beta]

Alternatively, you can use the `skipPhases` field under `InitConfiguration`.

## Using kubeadm init with a configuration file

### Caution:

The config file is still considered beta and may change in future versions.

It's possible to configure `kubeadm init` with a configuration file instead of command line flags, and some more advanced features may only be available as configuration file options. This file is passed using the `--config` flag and it must contain a `ClusterConfiguration` structure and optionally more structures separated by `---`. Mixing `--config` with others flags may not be allowed in some cases.

The default configuration can be printed out using the [kubeadm config print](#) command.

If your configuration is not using the latest version it is **recommended** that you migrate using the [kubeadm config migrate](#) command.

For more information on the fields and usage of the configuration you can navigate to our [API reference page](#).

## Using kubeadm init with feature gates

Kubeadm supports a set of feature gates that are unique to kubeadm and can only be applied during cluster creation with `kubeadm init`. These features can control the behavior of the cluster. Feature gates are removed after a feature graduates to GA.

To pass a feature gate you can either use the `--feature-gates` flag for `kubeadm init`, or you can add items into the `featureGates` field when you pass a [configuration file](#) using `--config`.

Passing [feature gates for core Kubernetes components](#) directly to kubeadm is not supported. Instead, it is possible to pass them by [Customizing components with the kubeadm API](#).

List of feature gates:

kubeadm feature gates

| Feature                          | Default | Alpha | Beta | GA |
|----------------------------------|---------|-------|------|----|
| EtcdLearnerMode                  | true    | 1.27  | 1.29 | -  |
| PublicKeysECDSA                  | false   | 1.19  | -    | -  |
| RootlessControlPlane             | false   | 1.22  | -    | -  |
| WaitForAllControlPlaneComponents | false   | 1.30  | -    | -  |

## Note:

Once a feature gate goes GA its value becomes locked to true by default.

Feature gate descriptions:

### EtcdLearnerMode

With this feature gate enabled, when joining a new control plane node, a new etcd member will be created as a learner and promoted to a voting member only after the etcd data are fully aligned.

### PublicKeysECDSA

Can be used to create a cluster that uses ECDSA certificates instead of the default RSA algorithm. Renewal of existing ECDSA certificates is also supported using `kubeadm certs renew`, but you cannot switch between the RSA and ECDSA algorithms on the fly or during upgrades.

### RootlessControlPlane

Setting this flag configures the kubeadm deployed control plane component static Pod containers for kube-apiserver, kube-controller-manager, kube-scheduler and etcd to run as non-root users. If the flag is not set, those components run as root. You can change the value of this feature gate before you upgrade to a newer version of Kubernetes.

### WaitForAllControlPlaneComponents

With this feature gate enabled kubeadm will wait for all control plane components (kube-apiserver, kube-controller-manager, kube-scheduler) on a control plane node to report status 200 on their `/healthz` endpoints. These checks are performed on `https://127.0.0.1:PORT/healthz`, where PORT is taken from `--secure-port` of a component. If you specify custom `--secure-port` values in the kubeadm configuration they will be respected. Without the feature gate enabled, kubeadm will only wait for the kube-apiserver on a control plane node to become ready. The wait process starts right after the kubelet on the host is started by kubeadm. You are advised to enable this feature gate in case you wish to observe a ready state from all control plane components during the kubeadm init or kubeadm join command execution.

List of deprecated feature gates:

kubeadm deprecated feature gates

| Feature                         | Default |
|---------------------------------|---------|
| UpgradeAddonsBeforeControlPlane | false   |

Feature gate descriptions:

### UpgradeAddonsBeforeControlPlane

This is as a **disabled** feature gate that was introduced for Kubernetes v1.28, in order to allow reactivating a legacy and deprecated behavior during cluster upgrade. For kubeadm versions prior to v1.28, kubeadm upgrades cluster addons (including CoreDNS and kube-proxy) immediately during kubeadm upgrade apply, regardless of whether there are other control plane instances that have not been upgraded. This may cause compatibility problems. Since v1.28, kubeadm defaults to a mode that always checks whether all the control plane instances have been upgraded before starting to upgrade the addons. This behavior is applied to both kubeadm upgrade apply and kubeadm upgrade node. kubeadm determines whether a control plane instance has been upgraded by checking whether the image of the kube-apiserver Pod has been upgraded. You must perform control plane instances upgrade sequentially or at least ensure that the last control plane instance upgrade is not started until all the other control plane instances have been

upgraded completely, and the addons upgrade will be performed after the last control plane instance is upgraded. The deprecated UpgradeAddonsBeforeControlPlane feature gate gives you a chance to keep the old upgrade behavior. You should not need this old behavior; if you do, you should consider changing your cluster or upgrade processes, as this feature gate will be removed in a future release.

List of removed feature gates:

kubeadm removed feature gates

| Feature                     | Alpha | Beta | GA   | Removed |
|-----------------------------|-------|------|------|---------|
| IPv6DualStack               | 1.16  | 1.21 | 1.23 | 1.24    |
| UnversionedKubeletConfigMap | 1.22  | 1.23 | 1.25 | 1.26    |

Feature gate descriptions:

IPv6DualStack

This flag helps to configure components dual stack when the feature is in progress. For more details on Kubernetes dual-stack support see [Dual-stack support with kubeadm](#).

UnversionedKubeletConfigMap

This flag controls the name of the [ConfigMap](#) where kubeadm stores kubelet configuration data. With this flag not specified or set to true, the ConfigMap is named kubelet-config. If you set this flag to false, the name of the ConfigMap includes the major and minor version for Kubernetes (for example: kubelet-config-1.30). Kubeadm ensures that RBAC rules for reading and writing that ConfigMap are appropriate for the value you set. When kubeadm writes this ConfigMap (during kubeadm init or kubeadm upgrade apply), kubeadm respects the value of UnversionedKubeletConfigMap. When reading that ConfigMap (during kubeadm join, kubeadm reset, kubeadm upgrade ...), kubeadm attempts to use unversioned ConfigMap name first; if that does not succeed, kubeadm falls back to using the legacy (versioned) name for that ConfigMap.

## Adding kube-proxy parameters

For information about kube-proxy parameters in the kubeadm configuration see:

- [kube-proxy reference](#)

For information about enabling IPVS mode with kubeadm see:

- [IPVS](#)

## Passing custom flags to control plane components

For information about passing flags to control plane components see:

- [control-plane-flags](#)

## Running kubeadm without an Internet connection

For running kubeadm without an Internet connection you have to pre-pull the required control-plane images.

You can list and pull the images using the kubeadm config images sub-command:

```
kubeadm config images list
kubeadm config images pull
```

You can pass `--config` to the above commands with a [kubeadm configuration file](#) to control the `kubernetesVersion` and `imageRepository` fields.

All default `registry.k8s.io` images that kubeadm requires support multiple architectures.

## Using custom images

By default, kubeadm pulls images from `registry.k8s.io`. If the requested Kubernetes version is a CI label (such as `ci/latest`) `gcr.io/k8s-staging-ci-images` is used.

You can override this behavior by using [kubeadm with a configuration file](#). Allowed customization are:

- To provide `kubernetesVersion` which affects the version of the images.
- To provide an alternative `imageRepository` to be used instead of `registry.k8s.io`.
- To provide a specific `imageRepository` and `imageTag` for `etcd` or `CoreDNS`.

Image paths between the default `registry.k8s.io` and a custom repository specified using `imageRepository` may differ for backwards compatibility reasons. For example, one image might have a subpath at `registry.k8s.io/subpath/image`, but be defaulted to `my.customrepository.io/image` when using a custom repository.

To ensure you push the images to your custom repository in paths that kubeadm can consume, you must:

- Pull images from the defaults paths at `registry.k8s.io` using `kubeadm config images {list|pull}`.
- Push images to the paths from `kubeadm config images list --config=config.yaml`, where `config.yaml` contains the custom `imageRepository`, and/or `imageTag` for `etcd` and `CoreDNS`.
- Pass the same `config.yaml` to `kubeadm init`.

## Custom sandbox (pause) images

To set a custom image for these you need to configure this in your [container runtime](#) to use the image. Consult the documentation for your container runtime to find out how to change this setting; for selected container runtimes, you can also find advice within the [Container Runtimes](#) topic.

## Uploading control-plane certificates to the cluster

By adding the flag `--upload-certs` to `kubeadm init` you can temporary upload the control-plane certificates to a Secret in the cluster. Please note that this Secret will expire automatically after 2 hours. The certificates are encrypted using a 32byte key that can be specified using `--certificate-key`. The same key can be used to download the certificates when additional control-plane nodes are joining, by passing `--control-plane` and `--certificate-key` to `kubeadm join`.

The following phase command can be used to re-upload the certificates after expiration:

```
kubeadm init phase upload-certs --upload-certs --config=SOME_YAML_FILE
```

**Note:**

A predefined `certificateKey` can be provided in `InitConfiguration` when passing the [configuration file](#) with `--config`.

If a predefined certificate key is not passed to `kubeadm init` and `kubeadm init` phase upload-certs a new key will be generated automatically.

The following command can be used to generate a new key on demand:

```
kubeadm certs certificate-key
```

## Certificate management with kubeadm

For detailed information on certificate management with kubeadm see [Certificate Management with kubeadm](#). The document includes information about using external CA, custom certificates and certificate renewal.

## Managing the kubeadm drop-in file for the kubelet

The kubeadm package ships with a configuration file for running the kubelet by systemd. Note that the kubeadm CLI never touches this drop-in file. This drop-in file is part of the kubeadm DEB/RPM package.

For further information, see [Managing the kubeadm drop-in file for systemd](#).

## Use kubeadm with CRI runtimes

By default kubeadm attempts to detect your container runtime. For more details on this detection, see the [kubeadm CRI installation guide](#).

## Setting the node name

By default, kubeadm assigns a node name based on a machine's host address. You can override this setting with the `--node-name` flag. The flag passes the appropriate [--hostname-override](#) value to the kubelet.

Be aware that overriding the hostname can [interfere with cloud providers](#).

## Automating kubeadm

Rather than copying the token you obtained from `kubeadm init` to each node, as in the [basic kubeadm tutorial](#), you can parallelize the token distribution for easier automation. To implement this automation, you must know the IP address that the control-plane node will have after it is started, or use a DNS name or an address of a load balancer.

1. Generate a token. This token must have the form `<6 character string>.<16 character string>`. More formally, it must match the regex: `[a-z0-9]{6}\.[a-z0-9]{16}`.

kubeadm can generate a token for you:

```
kubeadm token generate
```

- Start both the control-plane node and the worker nodes concurrently with this token. As
2. they come up they should find each other and form the cluster. The same `--token` argument can be used on both `kubeadm init` and `kubeadm join`.
  3. Similar can be done for `--certificate-key` when joining additional control-plane nodes. The key can be generated using:

```
kubeadm certs certificate-key
```

Once the cluster is up, you can use the `/etc/kubernetes/admin.conf` file from a control-plane node to talk to the cluster with administrator credentials or [Generating kubeconfig files for additional users](#).

Note that this style of bootstrap has some relaxed security guarantees because it does not allow the root CA hash to be validated with `--discovery-token-ca-cert-hash` (since it's not generated when the nodes are provisioned). For details, see the [kubeadm join](#).

## What's next

- [kubeadm init phase](#) to understand more about kubeadm init phases
- [kubeadm join](#) to bootstrap a Kubernetes worker node and join it to the cluster
- [kubeadm upgrade](#) to upgrade a Kubernetes cluster to a newer version
- [kubeadm reset](#) to revert any changes made to this host by kubeadm init or kubeadm join

# kubeadm join

This command initializes a Kubernetes worker node and joins it to the cluster.

Run this on any machine you wish to join an existing cluster

## Synopsis

When joining a kubeadm initialized cluster, we need to establish bidirectional trust. This is split into discovery (having the Node trust the Kubernetes Control Plane) and TLS bootstrap (having the Kubernetes Control Plane trust the Node).

There are 2 main schemes for discovery. The first is to use a shared token along with the IP address of the API server. The second is to provide a file - a subset of the standard kubeconfig file. The discovery/kubeconfig file supports token, client-go authentication plugins ("exec"), "tokenFile", and "authProvider". This file can be a local file or downloaded via an HTTPS URL. The forms are `kubeadm join --discovery-token abcdef.1234567890abcdef 1.2.3.4:6443`, `kubeadm join --discovery-file path/to/file.conf`, or `kubeadm join --discovery-file https://url/file.conf`. Only one form can be used. If the discovery information is loaded from a URL, HTTPS must be used. Also, in that case the host installed CA bundle is used to verify the connection.

If you use a shared token for discovery, you should also pass the `--discovery-token-ca-cert-hash` flag to validate the public key of the root certificate authority (CA) presented by the Kubernetes Control Plane. The value of this flag is specified as "`<hash-type>:<hex-encoded-value>`", where the supported hash type is "sha256". The hash is calculated over the bytes of the Subject Public Key Info (SPKI) object (as in RFC7469). This value is available in the output of "kubeadm init" or

can be calculated using standard tools. The `--discovery-token-ca-cert-hash` flag may be repeated multiple times to allow more than one public key.

If you cannot know the CA public key hash ahead of time, you can pass the `--discovery-token-unsafe-skip-ca-verification` flag to disable this verification. This weakens the kubeadm security model since other nodes can potentially impersonate the Kubernetes Control Plane.

The TLS bootstrap mechanism is also driven via a shared token. This is used to temporarily authenticate with the Kubernetes Control Plane to submit a certificate signing request (CSR) for a locally created key pair. By default, kubeadm will set up the Kubernetes Control Plane to automatically approve these signing requests. This token is passed in with the `--tls-bootstrap-token abcdef.1234567890abcdef` flag.

Often times the same token is used for both parts. In this case, the `--token` flag can be used instead of specifying each token individually.

The "join [api-server-endpoint]" command executes the following phases:

```
preflight Run join pre-flight checks
control-plane-prepare Prepare the machine for serving a control plane
/download-certs [EXPERIMENTAL] Download certificates shared among control-plane
nodes from the kubeadm-certs Secret
/certs Generate the certificates for the new control plane components
/kubeconfig Generate the kubeconfig for the new control plane components
/control-plane Generate the manifests for the new control plane components
kubelet-start Write kubelet settings, certificates and (re)start the kubelet
control-plane-join Join a machine as a control plane instance
/etc Add a new local etcd member
/update-status Register the new control-plane node into the ClusterStatus maintained in
the kubeadm-config ConfigMap (DEPRECATED)
/mark-control-plane Mark a node as a control-plane
wait-control-plane EXPERIMENTAL: Wait for the control plane to start
```

```
kubeadm join [api-server-endpoint] [flags]
```

## Options

|                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--apiserver-advertise-address</code> string                                                                                                                            |
| If the node should host a new control plane instance, the IP address the API Server will advertise it's listening on. If not set the default network interface will be used. |
| <code>--apiserver-bind-port</code> int32    Default: 6443                                                                                                                    |
| If the node should host a new control plane instance, the port for the API Server to bind to.                                                                                |
| <code>--certificate-key</code> string                                                                                                                                        |
| Use this key to decrypt the certificate secrets uploaded by init. The certificate key is a hex encoded string that is an AES key of size 32 bytes.                           |
| <code>--config</code> string                                                                                                                                                 |

|                                               |                                                                                                                                                                                                                                                                            |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                                               | A list of checks whose errors will be shown as warnings. Example: 'IsPrivilegedUser,Swap'. Value 'all' ignores errors from all checks.                                                                                                                                     |
| --node-name string                            |                                                                                                                                                                                                                                                                            |
|                                               | Specify the node name.                                                                                                                                                                                                                                                     |
| --patches string                              |                                                                                                                                                                                                                                                                            |
|                                               | Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". |

|                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --skip-phases strings                                                                                                                                                                                                                                                                                                |
| List of phases to be skipped                                                                                                                                                                                                                                                                                         |
| --tls-bootstrap-token string                                                                                                                                                                                                                                                                                         |
| Specify the token used to temporarily authenticate with the Kubernetes Control Plane while joining the node.                                                                                                                                                                                                         |
| --token string                                                                                                                                                                                                                                                                                                       |
| Use this token for both discovery-token and tls-bootstrap-token when those values are not provided.                                                                                                                                                                                                                  |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## The join workflow

kubeadm join bootstraps a Kubernetes worker node or a control-plane node and adds it to the cluster. This action consists of the following steps for worker nodes:

1. kubeadm downloads necessary cluster information from the API server. By default, it uses the bootstrap token and the CA key hash to verify the authenticity of that data. The root CA can also be discovered directly via a file or URL.
2. Once the cluster information is known, kubelet can start the TLS bootstrapping process.

The TLS bootstrap uses the shared token to temporarily authenticate with the Kubernetes API server to submit a certificate signing request (CSR); by default the control plane signs this CSR request automatically.

3. Finally, kubeadm configures the local kubelet to connect to the API server with the definitive identity assigned to the node.

For control-plane nodes additional steps are performed:

1. Downloading certificates shared among control-plane nodes from the cluster (if explicitly requested by the user).
2. Generating control-plane component manifests, certificates and kubeconfig.
3. Adding new local etcd member.

## Using join phases with kubeadm

Kubeadm allows you join a node to the cluster in phases using `kubeadm join phase`.

To view the ordered list of phases and sub-phases you can call `kubeadm join --help`. The list will be located at the top of the help screen and each phase will have a description next to it. Note that by calling `kubeadm join` all of the phases and sub-phases will be executed in this exact order.

Some phases have unique flags, so if you want to have a look at the list of available options add `--help`, for example:

```
kubeadm join phase kubelet-start --help
```

Similar to the [kubeadm init phase](#) command, `kubeadm join phase` allows you to skip a list of phases using the `--skip-phases` flag.

For example:

```
sudo kubeadm join --skip-phases=preflight --config=config.yaml
```

FEATURE STATE: Kubernetes v1.22 [beta]

Alternatively, you can use the `skipPhases` field in `JoinConfiguration`.

## Discovering what cluster CA to trust

The kubeadm discovery has several options, each with security tradeoffs. The right method for your environment depends on how you provision nodes and the security expectations you have about your network and node lifecycles.

### Token-based discovery with CA pinning

This is the default mode in kubeadm. In this mode, kubeadm downloads the cluster configuration (including root CA) and validates it using the token as well as validating that the root CA public key matches the provided hash and that the API server certificate is valid under the root CA.

The CA key hash has the format `sha256:<hex_encoded_hash>`. By default, the hash value is printed at the end of the `kubeadm init` command or in the output from the `kubeadm token create --print-join-command` command. It is in a standard format (see [RFC7469](#)) and can also be calculated by 3rd party tools or provisioning systems. For example, using the OpenSSL CLI:

```
openssl x509 -pubkey -in /etc/kubernetes/pki/ca.crt | openssl rsa -pubin -outform der 2>/dev/null | openssl dgst -sha256 -hex | sed 's/^.* //'
```

### Example kubeadm join commands:

For worker nodes:

```
kubeadm join --discovery-token abcdef.1234567890abcdef --discovery-token-ca-cert-hash sha256:1234..cdef 1.2.3.4:6443
```

For control-plane nodes:

```
kubeadm join --discovery-token abcdef.1234567890abcdef --discovery-token-ca-cert-hash sha256:1234..cdef --control-plane 1.2.3.4:6443
```

You can also call join for a control-plane node with `--certificate-key` to copy certificates to this node, if the `kubeadm init` command was called with `--upload-certs`.

#### **Advantages:**

- Allows bootstrapping nodes to securely discover a root of trust for the control-plane node even if other worker nodes or the network are compromised.
- Convenient to execute manually since all of the information required fits into a single `kubeadm join` command.

#### **Disadvantages:**

- The CA hash is not normally known until the control-plane node has been provisioned, which can make it more difficult to build automated provisioning tools that use `kubeadm`. By generating your CA in beforehand, you may work around this limitation.

### **Token-based discovery without CA pinning**

This mode relies only on the symmetric token to sign (HMAC-SHA256) the discovery information that establishes the root of trust for the control-plane. To use the mode the joining nodes must skip the hash validation of the CA public key, using `--discovery-token-unsafe-skip-ca-verification`. You should consider using one of the other modes if possible.

#### **Example kubeadm join command:**

```
kubeadm join --token abcdef.1234567890abcdef --discovery-token-unsafe-skip-ca-verification 1.2.3.4:6443
```

#### **Advantages:**

- Still protects against many network-level attacks.
- The token can be generated ahead of time and shared with the control-plane node and worker nodes, which can then bootstrap in parallel without coordination. This allows it to be used in many provisioning scenarios.

#### **Disadvantages:**

- If an attacker is able to steal a bootstrap token via some vulnerability, they can use that token (along with network-level access) to impersonate the control-plane node to other bootstrapping nodes. This may or may not be an appropriate tradeoff in your environment.

### **File or HTTPS-based discovery**

This provides an out-of-band way to establish a root of trust between the control-plane node and bootstrapping nodes. Consider using this mode if you are building automated provisioning using `kubeadm`. The format of the discovery file is a regular Kubernetes [kubeconfig](#) file.

In case the discovery file does not contain credentials, the TLS discovery token will be used.

## Example kubeadm join commands:

- `kubeadm join --discovery-file path/to/file.conf` (local file)
- `kubeadm join --discovery-file https://url/file.conf` (remote HTTPS URL)

## Advantages:

- Allows bootstrapping nodes to securely discover a root of trust for the control-plane node even if the network or other worker nodes are compromised.

## Disadvantages:

- Requires that you have some way to carry the discovery information from the control-plane node to the bootstrapping nodes. If the discovery file contains credentials you must keep it secret and transfer it over a secure channel. This might be possible with your cloud provider or provisioning tool.

## Use of custom kubelet credentials with kubeadm join

To allow kubeadm join to use predefined kubelet credentials and skip client TLS bootstrap and CSR approval for a new node:

1. From a working control plane node in the cluster that has `/etc/kubernetes/pki/ca.key` execute `kubeadm kubeconfig user --org system:nodes --client-name system:node:$NODE > kubelet.conf`. `$NODE` must be set to the name of the new node.
2. Modify the resulted `kubelet.conf` manually to adjust the cluster name and the server endpoint, or run `kubeadm kubeconfig user --config` (it accepts `InitConfiguration`).

If your cluster does not have the `ca.key` file, you must sign the embedded certificates in the `kubelet.conf` externally. For additional information, see [PKI certificates and requirements](#) and [Certificate Management with kubeadm](#).

1. Copy the resulting `kubelet.conf` to `/etc/kubernetes/kubelet.conf` on the new node.
2. Execute `kubeadm join` with the flag `--ignore-preflight-errors=FileAvailable--etc-kubernetes-kubelet.conf` on the new node.

## Securing your installation even more

The defaults for kubeadm may not work for everyone. This section documents how to tighten up a kubeadm installation at the cost of some usability.

### Turning off auto-approval of node client certificates

By default, there is a CSR auto-approver enabled that basically approves any client certificate request for a kubelet when a Bootstrap Token was used when authenticating. If you don't want the cluster to automatically approve kubelet client certs, you can turn it off by executing this command:

```
kubectrl delete clusterrolebinding kubeadm:node-autoapprove-bootstrap
```

After that, `kubeadm join` will block until the admin has manually approved the CSR in flight:

1. Using `kubectl get csr`, you can see that the original CSR is in the Pending state.

```
kubectl get csr
```

The output is similar to this:

| NAME                                                 | AGE | REQUESTOR | CONDITION |
|------------------------------------------------------|-----|-----------|-----------|
| node-csr-c69HXe7aYcqkS1bKmH4faEnHAWxn6i2bHZ2mD04jZyQ | 18s |           |           |
| system:bootstrap:878f07                              |     | Pending   |           |

2. `kubectl certificate approve` allows the admin to approve CSR. This action tells a certificate signing controller to issue a certificate to the requestor with the attributes requested in the CSR.

```
kubectl certificate approve node-csr-c69HXe7aYcqkS1bKmH4faEnHAWxn6i2bHZ2mD04jZyQ
```

The output is similar to this:

```
certificatesigningrequest "node-csr-c69HXe7aYcqkS1bKmH4faEnHAWxn6i2bHZ2mD04jZyQ" approved
```

3. This would change the CRS resource to Active state.

```
kubectl get csr
```

The output is similar to this:

| NAME                                                 | AGE | REQUESTOR       | CONDITION |
|------------------------------------------------------|-----|-----------------|-----------|
| node-csr-c69HXe7aYcqkS1bKmH4faEnHAWxn6i2bHZ2mD04jZyQ | 1m  |                 |           |
| system:bootstrap:878f07                              |     | Approved,Issued |           |

This forces the workflow that `kubeadm join` will only succeed if `kubectl certificate approve` has been run.

## Turning off public access to the cluster-info ConfigMap

In order to achieve the joining flow using the token as the only piece of validation information, a ConfigMap with some data needed for validation of the control-plane node's identity is exposed publicly by default. While there is no private data in this ConfigMap, some users might wish to turn it off regardless. Doing so will disable the ability to use the `--discovery-token` flag of the `kubeadm join` flow. Here are the steps to do so:

- Fetch the cluster-info file from the API Server:

```
kubectl -n kube-public get cm cluster-info -o jsonpath='{.data.kubeconfig}' | tee cluster-info.yaml
```

The output is similar to this:

```
apiVersion: v1
kind: Config
clusters:
```

```
- cluster:
 certificate-authority-data: <ca-cert>
 server: https://<ip>:<port>
 name: ""
contexts: []
current-context: ""
preferences: {}
users: []
```

- Use the cluster-info.yaml file as an argument to `kubeadm join --discovery-file`.
- Turn off public access to the cluster-info ConfigMap:

```
kubectrl -n kube-public delete rolebinding kubeadm:bootstrap-signer-clusterinfo
```

These commands should be run after `kubeadm init` but before `kubeadm join`.

## Using kubeadm join with a configuration file

### Caution:

The config file is still considered beta and may change in future versions.

It's possible to configure `kubeadm join` with a configuration file instead of command line flags, and some more advanced features may only be available as configuration file options. This file is passed using the `--config` flag and it must contain a `JoinConfiguration` structure. Mixing `--config` with others flags may not be allowed in some cases.

The default configuration can be printed out using the [kubeadm config print](#) command.

If your configuration is not using the latest version it is **recommended** that you migrate using the [kubeadm config migrate](#) command.

For more information on the fields and usage of the configuration you can navigate to our [API reference](#).

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node.
- [kubeadm token](#) to manage tokens for `kubeadm join`.
- [kubeadm reset](#) to revert any changes made to this host by `kubeadm init` or `kubeadm join`.

# kubeadm upgrade

`kubeadm upgrade` is a user-friendly command that wraps complex upgrading logic behind one command, with support for both planning an upgrade and actually performing it.

## kubeadm upgrade guidance

The steps for performing an upgrade using `kubeadm` are outlined in [this document](#). For older versions of `kubeadm`, please refer to older documentation sets of the Kubernetes website.

You can use `kubeadm upgrade diff` to see the changes that would be applied to static pod manifests.

In Kubernetes v1.15.0 and later, `kubeadm upgrade apply` and `kubeadm upgrade node` will also automatically renew the kubeadm managed certificates on this node, including those stored in kubeconfig files. To opt-out, it is possible to pass the flag `--certificate-renewal=false`. For more details about certificate renewal see the [certificate management documentation](#).

#### Note:

The commands `kubeadm upgrade apply` and `kubeadm upgrade plan` have a legacy `--config` flag which makes it possible to reconfigure the cluster, while performing planning or upgrade of that particular control-plane node. Please be aware that the upgrade workflow was not designed for this scenario and there are reports of unexpected results.

## kubeadm upgrade plan

Check which versions are available to upgrade to and validate whether your current cluster is upgradeable.

### Synopsis

Check which versions are available to upgrade to and validate whether your current cluster is upgradeable. This command can only run on the control plane nodes where the kubeconfig file "admin.conf" exists. To skip the internet check, pass in the optional [version] parameter.

```
kubeadm upgrade plan [version] [flags]
```

### Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-experimental-upgrades</code>                                                                                                      |
| Show unstable versions of Kubernetes as an upgrade alternative and allow upgrading to an alpha/beta/release candidate versions of Kubernetes.   |
| <code>--allow-missing-template-keys</code> Default: true                                                                                        |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
| <code>--allow-release-candidate-upgrades</code>                                                                                                 |
| Show release candidate versions of Kubernetes as an upgrade alternative and allow upgrading to a release candidate versions of Kubernetes.      |
| <code>--config</code> string                                                                                                                    |
| Path to a kubeadm configuration file.                                                                                                           |
| <code>-o, --experimental-output</code> string    Default: "text"                                                                                |

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm upgrade apply

Upgrade your Kubernetes cluster to the specified version

### Synopsis

Upgrade your Kubernetes cluster to the specified version

kubeadm upgrade apply [version]

## Options

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-experimental-upgrades         | Show unstable versions of Kubernetes as an upgrade alternative and allow upgrading to an alpha/beta/release candidate versions of Kubernetes.                                                                                                                                                                                                                                                                       |
| --allow-release-candidate-upgrades    | Show release candidate versions of Kubernetes as an upgrade alternative and allow upgrading to a release candidate versions of Kubernetes.                                                                                                                                                                                                                                                                          |
| --certificate-renewal   Default: true | Perform the renewal of certificates used by component changed during upgrades.                                                                                                                                                                                                                                                                                                                                      |
| --config string                       | Path to a kubeadm configuration file.                                                                                                                                                                                                                                                                                                                                                                               |
| --dry-run                             | Do not change any state, just output what actions would be performed.                                                                                                                                                                                                                                                                                                                                               |
| --etcd-upgrade   Default: true        | Perform the upgrade of etcd.                                                                                                                                                                                                                                                                                                                                                                                        |
| --feature-gates string                | A set of key=value pairs that describe feature gates for various features. Options are:<br>EtcdLearnerMode=true false (BETA - default=true)<br>PublicKeysECDSA=true false (DEPRECATED - default=false)<br>RootlessControlPlane=true false (ALPHA - default=false)<br>UpgradeAddonsBeforeControlPlane=true false (DEPRECATED - default=false)<br>WaitForAllControlPlaneComponents=true false (ALPHA - default=false) |
| -f, --force                           | Force upgrading although some requirements might not be met. This also implies non-interactive mode.                                                                                                                                                                                                                                                                                                                |

| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --patches string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Path to a directory that contains files named "target[suffix][+patchtype].extension". For example, "kube-apiserver0+merge.yaml" or just "etcd.json". "target" can be one of "kube-apiserver", "kube-controller-manager", "kube-scheduler", "etcd", "kubeletconfiguration". "patchtype" can be one of "strategic", "merge" or "json" and they match the patch formats supported by kubectl. The default "patchtype" is "strategic". "extension" must be either "json" or "yaml". "suffix" is an optional string that can be used to determine which patches are applied first alpha-numerically. |
| --print-config                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Specifies whether the configuration file that will be used in the upgrade should be printed or not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm upgrade node

Upgrade commands for a node in the cluster

### Synopsis

Upgrade commands for a node in the cluster

The "node" command executes the following phases:

```

preflight Run upgrade node pre-flight checks
control-plane Upgrade the control plane instance deployed on this node, if any
kubelet-config Upgrade the kubelet configuration for this node

```

## Options

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |               |

| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## What's next

- [kubeadm config](#) if you initialized your cluster using kubeadm v1.7.x or lower, to configure your cluster for kubeadm upgrade

# kubeadm config

During `kubeadm init`, kubeadm uploads the `ClusterConfiguration` object to your cluster in a `ConfigMap` called `kubeadm-config` in the `kube-system` namespace. This configuration is then read during `kubeadm join`, `kubeadm reset` and `kubeadm upgrade`.

You can use `kubeadm config print` to print the default static configuration that kubeadm uses for `kubeadm init` and `kubeadm join`.

### Note:

The output of the command is meant to serve as an example. You must manually edit the output of this command to adapt to your setup. Remove the fields that you are not certain about and kubeadm will try to default them on runtime by examining the host.

For more information on `init` and `join` navigate to [Using kubeadm init with a configuration file](#) or [Using kubeadm join with a configuration file](#).

For more information on using the kubeadm configuration API navigate to [Customizing components with the kubeadm API](#).

You can use `kubeadm config migrate` to convert your old configuration files that contain a deprecated API version to a newer, supported API version.

`kubeadm config validate` can be used for validating a configuration file.

`kubeadm config images list` and `kubeadm config images pull` can be used to list and pull the images that kubeadm requires.

## kubeadm config print

Print configuration

### Synopsis

This command prints configurations for subcommands provided. For details, see: <https://pkg.go.dev/k8s.io/kubernetes/cmd/kubeadm/app/apis/kubeadm#section-directories>

kubeadm config print [flags]

kubeadm config print init-defaults

Print default init configuration, that can be used for 'kubeadm init'

Synopsis

This command prints objects such as the default init configuration that is used for 'kubeadm init'.

Note that sensitive values like the Bootstrap Token fields are replaced with placeholder values like "abcdef.0123456789abcdef" in order to pass validation but not perform the real computation for creating a token.

kubeadm config print init-defaults [flags]

## kubeadm config migrate

Read an older version of the kubeadm configuration API types from a file, and output the similar config object for the newer version

## Synopsis

This command lets you convert configuration objects of older versions to the latest supported version, locally in the CLI tool without ever touching anything in the cluster. In this version of kubeadm, the following API versions are supported:

- kubeadm.k8s.io/v1beta3

Further, kubeadm can only write out config of version "kubeadm.k8s.io/v1beta3", but read both types. So regardless of what version you pass to the `--old-config` parameter here, the API object will be read, deserialized, defaulted, converted, validated, and re-serialized when written to stdout or `--new-config` if specified.

In other words, the output of this command is what kubeadm actually would read internally if you submitted this file to "kubeadm init"

```
kubeadm config migrate [flags]
```

## Options

|                                                                                                                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--allow-experimental-api</code>                                                                                                     |
| Allow migration to experimental, unreleased APIs.                                                                                         |
| <code>-h, --help</code>                                                                                                                   |
| help for migrate                                                                                                                          |
| <code>--new-config string</code>                                                                                                          |
| Path to the resulting equivalent kubeadm config file using the new API version. Optional, if not specified output will be sent to STDOUT. |
| <code>--old-config string</code>                                                                                                          |
| Path to the kubeadm config file that is using an old API version and should be converted. This flag is mandatory.                         |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--kubeconfig string</code> Default: "/etc/kubernetes/admin.conf"                                                                                       |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| <code>--rootfs string</code>                                                                                                                                 |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |

# kubeadm config validate

Read a file containing the kubeadm configuration API and report any validation problems

## Synopsis

This command lets you validate a kubeadm configuration API file and report any warnings and errors. If there are no errors the exit status will be zero, otherwise it will be non-zero. Any unmarshaling problems such as unknown API fields will trigger errors. Unknown API versions and fields with invalid values will also trigger errors. Any other errors or warnings may be reported depending on contents of the input file.

In this version of kubeadm, the following API versions are supported:

- kubeadm.k8s.io/v1beta3

```
kubeadm config validate [flags]
```

## Options

|                                                    |
|----------------------------------------------------|
| --allow-experimental-api                           |
| Allow validation of experimental, unreleased APIs. |
| --config string                                    |
| Path to a kubeadm configuration file.              |
| -h, --help                                         |
| help for validate                                  |

| Choose a container registry to pull control plane images from                                                                                                                                                                                                                                                                                                                                                       |                            |
| <code>--kubernetes-version</code> string                                                                                                                                                                                                                                                                                                                                                                            | Default: "stable-1"        |

Choose a specific Kubernetes version for the control plane.

## Options inherited from parent commands

|                                                                                                                                                              |                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| <code>--kubeconfig string</code>                                                                                                                             | Default: "/etc/kubernetes/admin.conf" |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |                                       |
| <code>--rootfs string</code>                                                                                                                                 |                                       |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |                                       |

## What's next

- [kubeadm upgrade](#) to upgrade a Kubernetes cluster to a newer version

# kubeadm reset

Performs a best effort revert of changes made by `kubeadm init` or `kubeadm join`.

Performs a best effort revert of changes made to this host by 'kubeadm init' or 'kubeadm join'

## Synopsis

Performs a best effort revert of changes made to this host by 'kubeadm init' or 'kubeadm join'

The "reset" command executes the following phases:

|                    |                             |
|--------------------|-----------------------------|
| preflight          | Run reset pre-flight checks |
| remove-etcd-member | Remove a local etcd member. |
| cleanup-node       | Run cleanup node.           |

`kubeadm reset [flags]`

## Options

|                                                                                                  |                                |
|--------------------------------------------------------------------------------------------------|--------------------------------|
| <code>--cert-dir string</code>                                                                   | Default: "/etc/kubernetes/pki" |
| The path to the directory where the certificates are stored. If specified, clean this directory. |                                |
| <code>--cleanup-tmp-dir</code>                                                                   |                                |
| Cleanup the "/etc/kubernetes/tmp" directory                                                      |                                |
| <code>--config string</code>                                                                     |                                |

|                                                                           |                                                                                                                                                                                              |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                           | Path to a kubeadm configuration file.                                                                                                                                                        |
| <code>--cri-socket</code> string                                          |                                                                                                                                                                                              |
|                                                                           | Path to the CRI socket to connect. If empty kubeadm will try to auto-detect this value; use this option only if you have more than one CRI installed or if you have non-standard CRI socket. |
| <code>--dry-run</code>                                                    |                                                                                                                                                                                              |

|-------------------------------------------------------------|
| <code>--rootfs</code> string                                |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## Reset workflow

kubeadm reset is responsible for cleaning up a node local file system from files that were created using the kubeadm init or kubeadm join commands. For control-plane nodes reset also removes the local stacked etcd member of this node from the etcd cluster.

kubeadm reset phase can be used to execute the separate phases of the above workflow. To skip a list of phases you can use the `--skip-phases` flag, which works in a similar way to the kubeadm join and kubeadm init phase runners.

## External etcd clean up

`kubeadm reset` will not delete any etcd data if external etcd is used. This means that if you run `kubeadm init` again using the same etcd endpoints, you will see state from previous clusters.

To wipe etcd data it is recommended you use a client like `etcdctl`, such as:

```
etcdctl del "" --prefix
```

See the [etcd documentation](#) for more information.

## Graceful kube-apiserver shutdown

If you have your kube-apiserver configured with the `--shutdown-delay-duration` flag, you can run the following commands to attempt a graceful shutdown for the running API server Pod, before you run `kubeadm reset`:

```
yq eval -i '.spec.containers[0].command = []' /etc/kubernetes/manifests/kube-apiserver.yaml
timeout 60 sh -c 'while pgrep kube-apiserver >/dev/null; do sleep 1; done' || true
```

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to bootstrap a Kubernetes worker node and join it to the cluster

# kubeadm token

Bootstrap tokens are used for establishing bidirectional trust between a node joining the cluster and a control-plane node, as described in [authenticating with bootstrap tokens](#).

`kubeadm init` creates an initial token with a 24-hour TTL. The following commands allow you to manage such a token and also to create and manage new ones.

## kubeadm token create

Create bootstrap tokens on the server

### Synopsis

This command will create a bootstrap token for you. You can specify the usages for this token, the "time to live" and an optional human friendly description.

The `[token]` is the actual token to write. This should be a securely generated random token of the form `"[a-z0-9]{6}.[a-z0-9]{16}"`. If no `[token]` is given, `kubeadm` will generate a random token instead.

```
kubeadm token create [token]
```

|                                                                                                                                                                                                                                  |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| --certificate-key string                                                                                                                                                                                                         |  |
| When used together with '--print-join-command', print the full 'kubeadm join' flag needed to join the cluster as a control-plane. To create a new certificate key you must use 'kubeadm init phase upload-certs --upload-certs'. |  |
| --config string                                                                                                                                                                                                                  |  |
| Path to a kubeadm configuration file.                                                                                                                                                                                            |  |
| --description string                                                                                                                                                                                                             |  |
| A human friendly description of how this token is used.                                                                                                                                                                          |  |
| --groups strings    Default: "system:bootstrappers:kubeadm:default-node-token"                                                                                                                                                   |  |
| Extra groups that this token will authenticate as when used for authentication. Must match "\Asystem:bootstrappers:[a-z0-9:-]{0,255}[a-z0-9]\z"                                                                                  |  |
| -h, --help                                                                                                                                                                                                                       |  |
| help for create                                                                                                                                                                                                                  |  |
| --print-join-command                                                                                                                                                                                                             |  |
| Instead of printing only the token, print the full 'kubeadm join' flag needed to join the cluster using the token.                                                                                                               |  |
| --ttl duration    Default: 24h0m0s                                                                                                                                                                                               |  |
| The duration before the token is automatically deleted (e.g. 1s, 2m, 3h). If set to '0', the token will never expire                                                                                                             |  |
| --usages strings    Default: "signing,authentication"                                                                                                                                                                            |  |
| Describes the ways in which this token can be used. You can pass --usages multiple times or provide a comma separated list of options. Valid options: [signing,authentication]                                                   |  |

## Options inherited from parent commands

|                                                              |  |
|--------------------------------------------------------------|--|
| --dry-run                                                    |  |
| Whether to enable dry-run mode or not                        |  |
| --kubeconfig string    Default: "/etc/kubernetes/admin.conf" |  |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --rootfs string                                                                                                                                              |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |

## kubeadm token delete

Delete bootstrap tokens on the server

### Synopsis

This command will delete a list of bootstrap tokens for you.

The [token-value] is the full Token of the form "[a-z0-9]{6}.[a-z0-9]{16}" or the Token ID of the form "[a-z0-9]{6}" to delete.

```
kubeadm token delete [token-value] ...
```

### Options

|                 |
|-----------------|
| -h, --help      |
| help for delete |

### Options inherited from parent commands

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --dry-run                                                                                                                                                    |
| Whether to enable dry-run mode or not                                                                                                                        |
| --kubeconfig string   Default: "/etc/kubernetes/admin.conf"                                                                                                  |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --rootfs string                                                                                                                                              |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |

## kubeadm token generate

Generate and print a bootstrap token, but do not create it on the server

## Synopsis

This command will print out a randomly-generated bootstrap token that can be used with the "init" and "join" commands.

You don't have to use this command in order to generate a token. You can do so yourself as long as it is in the format "[a-z0-9]{6}.[a-z0-9]{16}". This command is provided for convenience to generate tokens in the given format.

You can also use "kubeadm init" without specifying a token and it will generate and print one for you.

```
kubeadm token generate [flags]
```

## Options

|                   |
|-------------------|
| -h, --help        |
| help for generate |

## Options inherited from parent commands

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --dry-run                                                                                                                                                    |
| Whether to enable dry-run mode or not                                                                                                                        |
| --kubeconfig string   Default: "/etc/kubernetes/admin.conf"                                                                                                  |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --rootfs string                                                                                                                                              |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |

## kubeadm token list

List bootstrap tokens on the server

## Synopsis

This command will list all bootstrap tokens for you.

```
kubeadm token list [flags]
```

## Options

|                                               |
|-----------------------------------------------|
| --allow-missing-template-keys   Default: true |
|-----------------------------------------------|

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and jsonpath output formats. |
| -o, --experimental-output string    Default: "text"                                                                                             |
| Output format. One of: text json yaml go-template go-template-file template templatefile jsonpath jsonpath-as-json jsonpath-file.               |
| -h, --help                                                                                                                                      |
| help for list                                                                                                                                   |
| --show-managed-fields                                                                                                                           |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                   |

## Options inherited from parent commands

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --dry-run                                                                                                                                                    |
| Whether to enable dry-run mode or not                                                                                                                        |
| --kubeconfig string    Default: "/etc/kubernetes/admin.conf"                                                                                                 |
| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --rootfs string                                                                                                                                              |
| [EXPERIMENTAL] The path to the 'real' host root filesystem.                                                                                                  |

## What's next

- [kubeadm join](#) to bootstrap a Kubernetes worker node and join it to the cluster

# kubeadm version

This command prints the version of kubeadm.

Print the version of kubeadm

## Synopsis

Print the version of kubeadm

```
kubeadm version [flags]
```

## Options

|                                                                 |
|-----------------------------------------------------------------|
| -h, --help                                                      |
| help for version                                                |
| -o, --output string                                             |
| Output format; available options are 'yaml', 'json' and 'short' |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

# kubeadm alpha

### Caution:

kubeadm alpha provides a preview of a set of features made available for gathering feedback from the community. Please try it out and give us feedback!

Currently there are no experimental commands under kubeadm alpha.

## What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster

# kubeadm certs

kubeadm certs provides utilities for managing certificates. For more details on how these commands can be used, see [Certificate Management with kubeadm](#).

## kubeadm certs

A collection of operations for operating Kubernetes certificates.

Renew certificates for a Kubernetes cluster

## Synopsis

This command is not meant to be run on its own. See list of available subcommands.

```
kubeadm certs renew [flags]
```

## Options

|            |
|------------|
| -h, --help |
|------------|

|                |
|----------------|
| help for renew |
|----------------|

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

Renew all available certificates

## Synopsis

Renew all known certificates necessary to run the control plane. Renewals are run unconditionally, regardless of expiration date. Renewals can also be run individually for more control.

```
kubeadm certs renew all [flags]
```

## Options

|                                                                                                                                                              |                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| --cert-dir string                                                                                                                                            | Default: "/etc/kubernetes/pki"        |
| The path where to save the certificates                                                                                                                      |                                       |
| --config string                                                                                                                                              |                                       |

Renew the certificate embedded in the kubeconfig file for the admin to use and for kubeadm itself

## Synopsis

Renew the certificate embedded in the kubeconfig file for the admin to use and for kubeadm itself.

Renewals run unconditionally, regardless of certificate expiration date; extra attributes such as SANs will be based on the existing file/certificates, there is no need to resupply them.

Renewal by default tries to use the certificate authority in the local PKI managed by kubeadm; as alternative it is possible to use K8s certificate API for certificate renewal, or as a last option, to generate a CSR request.

After renewal, in order to make changes effective, is required to restart control-plane components and eventually re-distribute the renewed certificate in case the file is used elsewhere.

```
kubeadm certs renew admin.conf [flags]
```

## Options

|                                                                                                                                                              |                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| <code>--cert-dir</code> string                                                                                                                               | Default: "/etc/kubernetes/pki"        |
| The path where to save the certificates                                                                                                                      |                                       |
| <code>--config</code> string                                                                                                                                 |                                       |
| Path to a kubeadm configuration file.                                                                                                                        |                                       |

Renew the certificate the apiserver uses to access etcd

## Synopsis

Renew the certificate the apiserver uses to access etcd.

Renewals run unconditionally, regardless of certificate expiration date; extra attributes such as SANs will be based on the existing file/certificates, there is no need to resupply them.

Renewal by default tries to use the certificate authority in the local PKI managed by kubeadm; as alternative it is possible to use K8s certificate API for certificate renewal, or as a last option, to generate a CSR request.

After renewal, in order to make changes effective, is required to restart control-plane components and eventually re-distribute the renewed certificate in case the file is used elsewhere.

```
kubeadm certs renew apiserver-etcd-client [flags]
```

Options

|                                                                                                                                                              |                                       |

Renew the certificate embedded in the kubeconfig file for the controller manager to use

## Synopsis

Renew the certificate embedded in the kubeconfig file for the controller manager to use.

Renewals run unconditionally, regardless of certificate expiration date; extra attributes such as SANs will be based on the existing file/certificates, there is no need to resupply them.

Renewal by default tries to use the certificate authority in the local PKI managed by kubeadm; as alternative it is possible to use K8s certificate API for certificate renewal, or as a last option, to generate a CSR request.

After renewal, in order to make changes effective, is required to restart control-plane components and eventually re-distribute the renewed certificate in case the file is used elsewhere.

```
kubeadm certs renew controller-manager.conf [flags]
```

Renewals run unconditionally, regardless of certificate expiration date; extra attributes such as SANs will be based on the existing file/certificates, there is no need to resupply them.

Renewal by default tries to use the certificate authority in the local PKI managed by kubeadm; as alternative it is possible to use K8s certificate API for certificate renewal, or as a last option, to generate a CSR request.

After renewal, in order to make changes effective, is required to restart control-plane components and eventually re-distribute the renewed certificate in case the file is used elsewhere.

kubeadm certs renew scheduler.conf [flags]

Options

|                                                                                                                                                              |                                       |

kubeadm certs certificate-key

This command can be used to generate a new control-plane certificate key. The key can be passed as --certificate-key to [kubeadm init](#) and [kubeadm join](#) to enable the automatic copy of certificates when joining additional control-plane nodes.

- [certificate-key](#)

Generate certificate keys

## Synopsis

This command will print out a secure randomly-generated certificate key that can be used with the "init" command.

You can also use "kubeadm init --upload-certs" without specifying a certificate key and it will generate and print one for you.

```
kubeadm certs certificate-key [flags]
```

## Options

|                          |
|--------------------------|
| -h, --help               |
| help for certificate-key |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |

## kubeadm certs check-expiration

This command checks expiration for the certificates in the local PKI managed by kubeadm. For more details see [Check certificate expiration](#).

- [check-expiration](#)

Check certificates expiration for a Kubernetes cluster

## Synopsis

Checks expiration for the certificates in the local PKI managed by kubeadm.

```
kubeadm certs check-expiration [flags]
```

## Options

|                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------|
| --allow-missing-template-keys    Default: true                                                                                                  |
| If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to goyaml and jsonpath output formats. |
| --cert-dir string    Default: "/etc/kubernetes/pki"                                                                                             |
| The path where to save the certificates                                                                                                         |
| --config string                                                                                                                                 |

|                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Path to a kubeadm configuration file.                                                                                                                        |
| -o, --experimental-output string    Default: "text"                                                                                                          |

| The kubeconfig file to use when talking to the cluster. If the flag is not set, a set of standard locations can be searched for an existing kubeconfig file. |
| --show-managed-fields                                                                                                                                        |
| If true, keep the managedFields when printing objects in JSON or YAML format.                                                                                |

## Options inherited from parent commands

|                                                             |
|-------------------------------------------------------------|
| --rootfs string                                             |
| [EXPERIMENTAL] The path to the 'real' host root filesystem. |

## kubeadm certs generate-csr

This command can be used to generate keys and CSRs for all control-plane certificates and kubeconfig files. The user can then sign the CSRs with a CA of their choice. To read more information on how to use the command see [Signing certificate signing requests \(CSR\) generated by kubeadm](#).

- [generate-csr](#)

Generate keys and certificate signing requests

### Synopsis

Generates keys and certificate signing requests (CSRs) for all the certificates required to run the control plane. This command also generates partial kubeconfig files with private key data in the "users > user > client-key-data" field, and for each kubeconfig file an accompanying ".csr" file is created.

This command is designed for use in [Kubeadm External CA Mode](#). It generates CSRs which you can then submit to your external certificate authority for signing.

The PEM encoded signed certificates should then be saved alongside the key files, using ".crt" as the file extension, or in the case of kubeconfig files, the PEM encoded signed certificate should

be base64 encoded and added to the kubeconfig file in the "users > user > client-certificate-data" field.

```
kubeadm certs generate-csr [flags]
```

Examples

```
The following command will generate keys and CSRs for all control-plane certificates and kubeconfig files:
kubeadm certs generate-csr --kubeconfig-dir /tmp/etc-k8s --cert-dir /tmp/etc-k8s/pki
```

Options

| --kubeconfig-dir string    Default: "/etc/kubernetes" |                                             |
|                                                       | The path where to save the kubeconfig file. |

Options inherited from parent commands

|                 |                                                             |
|-----------------|-------------------------------------------------------------|
| --rootfs string |                                                             |
|                 | [EXPERIMENTAL] The path to the 'real' host root filesystem. |

What's next

- [kubeadm init](#) to bootstrap a Kubernetes control-plane node
- [kubeadm join](#) to connect a node to the cluster
- [kubeadm reset](#) to revert any changes made to this host by kubeadm init or kubeadm join

kubeadm init phase

kubeadm init phase enables you to invoke atomic steps of the bootstrap process. Hence, you can let kubeadm do some of the work and you can fill in the gaps if you wish to apply customization.

kubeadm init phase is consistent with the [kubeadm init workflow](#), and behind the scene both use the same code.

# kubeadm init phase preflight

Using this command you can execute preflight checks on a control-plane node.

- [preflight](#)

Run pre-flight checks

## Synopsis

Run pre-flight checks for kubeadm init.

```
kubeadm init phase preflight [flags]
```

## Examples

```
Run pre-flight checks for kubeadm init using a config file.
kubeadm init phase preflight --config kubeadm-config.yaml
```
